**A supervisory control system operating entirely on alternating current and possessing great reliability is described in this article. With a suitable switchboard arrangement, the operator is said to be able to visualize switching conditions at a glance; the system has the further advantage of employing only equipment with which operators are familiar.**

BECAUSE of the rapid extension of electric power systems and the progress of electrification of railroads, the control engineer has been called upon to provide solutions to increasingly intricate control problems. Coordination between those operations led to their concentration into the hands of a single operator or dispatcher, and the adoption of automatic and of remotely controlled substations. In order to be able to control equipment located at appreciable distances it was necessary to reduce to a minimum the number of wires required for transmitting a large number of different signals; this led to the adoption of different designs of supervisory control. At the time of the adoption of those systems it was felt that only a d-c. system operating from a battery would be sufficiently reliable, as a system directly supplied by the power lines to be controlled would be affected by disturbances in these lines, at times when supervision most urgently is required.

Operating on alternating current the system described in this article thus is something of an innovation. Different means may be used for insuring a dependable a-c. supply: The supply can be obtained in any of the interconnected stations, and may consist of a small motor-generator set, supplied from the station battery. This may be dispensed with, however, if the house supply of a generating station can be made available, as this supply is not affected by any disturbances to the high voltage lines feeding the controlled substations. Another alternative is to obtain voltage from the power lines at the controlling station and at each controlled substation if these latter are fed from the same power system. In this case the supervisory system will be dead only if the power fails simultaneously at all feeding points. In either case disturbances in the low voltage side of the controlled substations will not affect the supervisory system.

In networks with many internal connections it may be felt that the presence of normal voltage on the substation bus may be depended on at all times, so that each station can be supplied independently of each other, thereby eliminating the necessity of running two supply line wires between stations; a single return wire then can be used instead. In some cases an additional degree of safety can be obtained if a supervisory control system of this kind is supplied from one high voltage network while controlling another independent network. Each individual case will indicate the best current supply to be used.

Great reliability has been the attribute most sought in the development of this control system. It employs equipment of a sturdy type used in the past in relay applications; such apparatus is little subject to disturbance by even severe inductive interference, and further it can be protected from disturbances by the insertion of insulating transformers into the lines. The system is of the synchronous selector type, each station comprising one selector, started from its rest position when an operation is to be performed, and returned to this position after the operation has been completed. In Fig. 1 is shown diagrammatically the connections of a controlling station *I* and a controlled station *II* connected by five line wires. Equipment sufficient

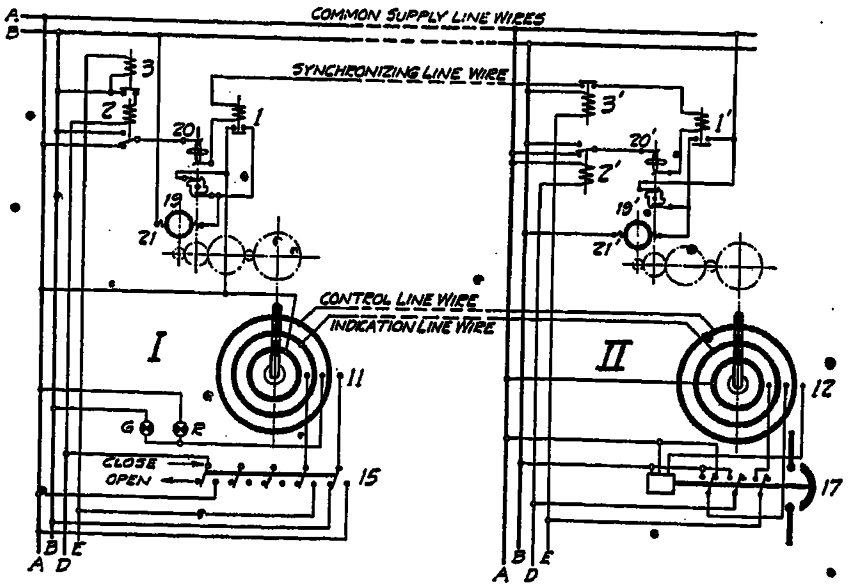

Fig. 1. Simplified diagram of a-c. supervisory system

only for illustrating the principle of operation of the selectors and the control of a circuit beaker is included in this diagram.

Selectors have been built with as many as 67 operating positions. These selectors are driven by a motor of remarkable simplicity and reliability, and one which has proved its worth in many years of service in central station and substation relays. (See Fig. 2.) It has been found that an operating time of from $^1/_3$ to $^1/_2$ sec. per step permits satisfactory operation of all the relays.

Referring to the simplified circuit of Fig. 1, the controlling station is assumed to be provided with an a-c. source supplying auxiliary busbars *A* and *B* and, over supply line wires, a set of similar auxiliary busbars, in the controlled station. Each station possesses also a starting bus *D* and a stopping bus *E* for controlling the operation of the selectors. If the selector arms are assumed to be in the rest position, as shown in Fig. 1, and it is desired to close circuit breaker *17*, control switch *15* of the circuit breaker is moved to the "close" position. This control switch is provided with several contacts, one of which connects starting bus *D* to busbar *A*, thereby energizing starting relay *2*. Until the starting relay is energized, the synchronizing line wire is connected to busbar *A* in both stations *I* and *II*, and therefore is without current. When the starting relay *2* operates, it connects one end of the synchronizing line to busbar *B;* the synchronizing line thus receives current, energizing selector relays *1* and *1'*. The latter connect to the busbars the selector motors *21* and *21'*, which start to rotate. This rotation is transmitted to contacts *19* and *19'*, which first connect the motors directly to the busbars, to contacts *20* and *20'* which open the synchronizing line, and through the two-tooth pinions to the selector arms which move to the first step. When this step is reached, contacts *20* and *20'* first reclose the synchronizing line, and contacts *19* and *19'* then disconnect the motors from the busbars. Starting relay *2* still being closed, another current impulse is sent over the synchronizing line, reenergizing selector relays *1* and *1'* before contacts *19* and *19'* open, thereby initiating another one step motion of the selector arms through the same sequence of operations.

Each selector arm thus can leave a step only if this step also has been reached by the other selector arm; motion of the selectors is obtained independently until they both again reach the following step. If one of the selectors should fail to operate while between two steps, the other selector would be unable to proceed; means are provided also for stopping the selectors if either one should jam on a step or fail to return to its rest position. In normal operation the two selector arms proceed over the

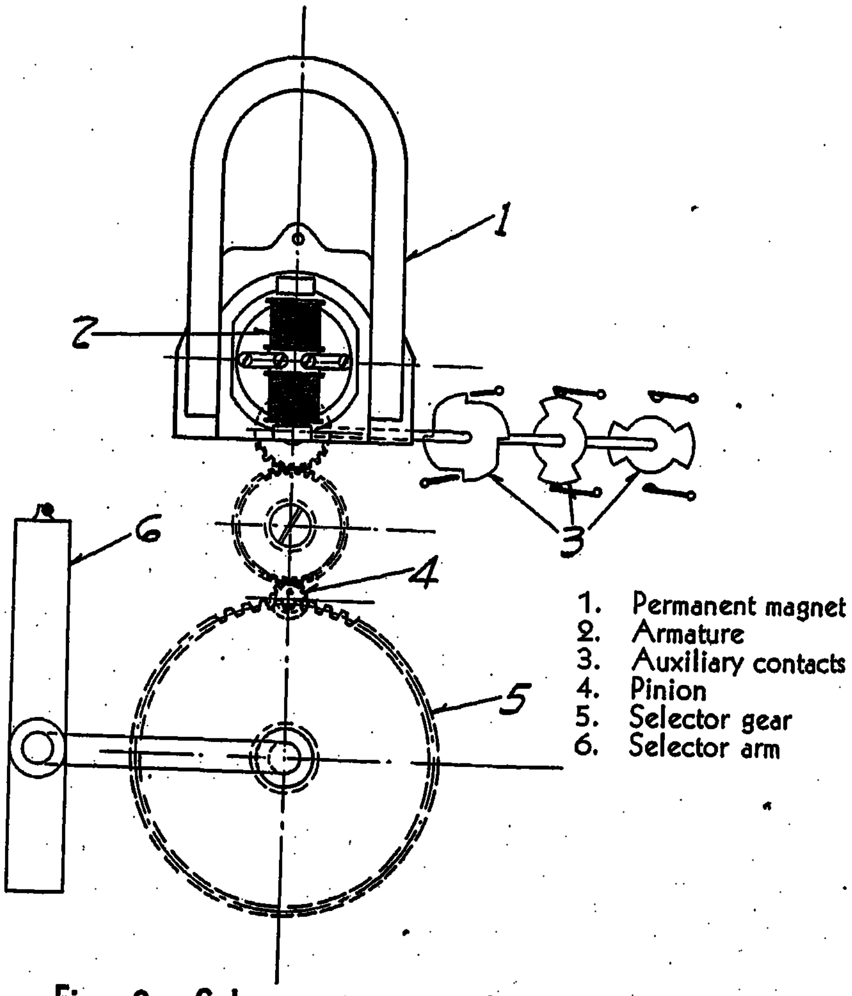

Fig. 2. Selector motor and driving mechanism

successive steps without stopping until both reach the step assigned for the control of circuit breaker *17*.

One of the brushes of selector *II* then connects busbar *A* through the control switch to the stopping bus *E;* stopping relay *3* then is energized and opens the circuit of starting relay *2*, which reconnects the synchronizing line to busbar *A* as when the system was at rest. Selector relays *1* and *1'* therefore are deenergized and the selector arms remain at standstill. Another brush of selector *II* then sends the control impulse over the control line wire and over selector *12* to the control circuit of the circuit breaker, causing it to close; the circuit breaker auxiliary contacts then send an indicating signal back over the indicating line wire.

When the circuit breaker trips automatically, it energizes starting relay *2'* which sets the two selectors in motion, in the same manner as when starting relay *2* is energized. The two selectors are stopped by means of stopping relay *3'* the return indication then being transmitted over the indicating line wire. The operator must acknowledge the tripping by moving the breaker control switch to the "open" position, and suitable relays prevent the initiation of a control operation or even the completion of an operation initiated before the tripping, until such acknowledgment is made. Thus when the operator wishes to perform a control operation, he is assured positively that while that operation is being completed, the equipment which this operation does not affect will still be in the condition shown by the indications on his switchboard. At the same time, this condition can be the result only of operations either initiated or acknowledged by himself by means of his control switches. In this manner the danger of the operator becoming confused and performing undesired operations is reduced to a minimum.

After an operation is completed, the selectors are returned by suitable relays to their rest positions. In addition to the foregoing provisions, proper control of a circuit breaker requires means for preventing automatic reclosing after tripping and consequent "pumping"; to take care of this, automatic tripping is indicated to the operator by blinking of the control lamp and by the ringing of a bell.

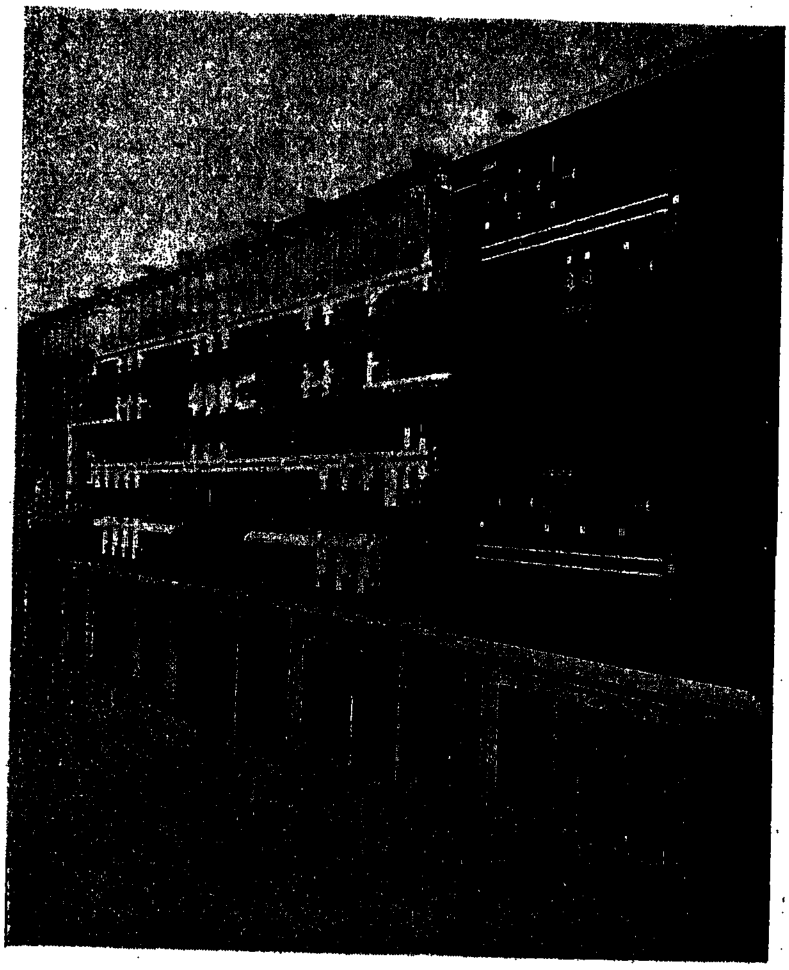

Fig. 3. Rear view of partially assembled luminous switchboard

Analogous circuits can be provided for other control and supervision operations such as the reading of meter indications, automatic position indication of manually operated disconnecting switches, alarm indications to warn of excessive temperatures, or other disturbances in the substation. The system can be modified easily to meet local conditions, and a single selector in the controlling station can be used for controlling several selectors in outlying stations.

Control switches, selectors, control lamps, and the various relays, can be mounted in different ways on switchboards or control desks. A suggested disposition applicable both to manual and to supervisory control which enables the operator to visualize at all times the condition of the system which he is controlling, is described as follows: The control switches are installed on a switch desk in front of the switchboard the handles of the switches forming part of a set of dummy buses so that the positions of all circuit breakers can be visualized. The switchboard is built from sheets of glass covered by an opaque paint leaving transparencies which form a diagram of the buses and lines duplicating the dummy set of buses on the switch desk. Indicating lamps are disposed behind the switchboard so as to show in proper colors the positions of the circuit breakers. Additional indicating lamps indicate whether or not the buses and lines are energized, for which purpose they are controlled by suitable relays connected to the circuit breaker controlling circuits. Additional transparencies provided in the lines can be used for indicating the readings of ammeters, voltmeters, or other instruments. Each of these transparencies discloses a meter box having a ground glass front graduated so as to provide a scale on which the readings are given by the shadow of the moving element of one or of several instruments. In this manner each meter is so located that it is immediately apparent to which circuit the reading refers. (See Figs. 3 and 4.)

This method of enabling the operator to visualize at a glance the condition of the network and the changes occurring therein, the position of the switching equipment, and the location of meter reading, greatly facilitates the supervisory operations and reduces the chances of performing wrong operations. In addition, the equipment is of a type with which the operators and maintenance crews are familiar, so that no special training is required for the personnel. These two advantages together with the flexibility and reliability of the equipment should make this system of particular interest to operating engineers.

COMMUNICATION has advanced in many respects during the past decade. In carrier current communication over submarine cables this advance has been such that three telephone circuits are provided over the new Key West-Havana cable where each of the three earlier cables, installed ten years ago, provide only one. Furthermore, the new cable is but little larger than the three previously installed. ("Key West-Havana Submarine Telephone Cable System," A.I.E.E. TRANS., v. 41, 1922, p. 1–19.) This latest cable was placed in service in January 1931, and like the three cables just mentioned is owned by the Cuban-American Telephone and Telegraph Company, an organization controlled jointly by the American Telephone and Telegraph Company and the Cuban Telephone Company, and providing telephone facilities between the United States and Cuba.

The new cable, which has been designated the 1930 cable is the longest deep sea telephone cable in existence; also it is unique in being the longest telephone cable circuit without intermediate repeaters and without inductive loading. It is about 3.7 nautical miles (1 nautical mile = 6,087 ft.) longer than the longest of the 1921 cables. The design of the cable is such as to satisfy economically the need for more circuits by an adaptation of standard carrier apparatus. The design was made sufficiently liberal, however, so that certain further development work would make it possible to obtain over the same cable still more facilities when these are required.

a transmission standpoint, the feature of most interest is the unusually low receiving levels at which operation is carried on successfully. (See Fig. 1.) Of importance also is the fact that the new cable is operated over a far wider frequency range than are the older cables. Whereas the old cables are operated only up to 3,800 cycles per sec., the new cable at present is being operated at frequencies as high as 28,000 cycles per sec., and can operate at still higher frequencies.

## PARAGUTTA INSULATION USED

Paragutta insulation is the feature of the new cable which has enabled such great improvement to be attained. This material developed at the Bell Telephone Laboratories is composed of deproteinized rubber, deresinated balata, and wax. It has been described in detail by A. R. Kemp ("Paragutta, A New Insulating Material for Submarine Cables," *Jl. of the Franklin Inst.*, v. 211, Jan. 1931, p. 37). Heretofore submarine cables having waterproof insulation have almost invariably been insulated with gutta-percha or balata, or a mixture of these substances; an exception to this is the Catalina Island cables which are insulated with a special rubber mixture ("Carrier Current Communication on Submarine Cables," H. W. Hitchcock, A.I.E.E. TRANS., v. 45, 1926, p. 923–9). Paragutta has better electrical properties than any of these materials.

As shown by Table I, paragutta possesses a smaller dielectric constant and a smaller leakance than

. New Key West-Havana Carrier Telephone Cable," presented at nter convention, New York, N. Y., Jan. 25–29, 1932.

gutta-percha. (The term leakance as used here includes all energy losses in the dielectric.) This property permits a considerable reduction in the size of a cable for a given attenuation. The decrease in size due to the use of paragutta varies of course with the size of the cable, but some idea of its amount may be obtained from the fact that a cable insulated with gutta-percha of the sort used in the 1921 cables would weigh 45 per cent more and cost about 65 per cent more than the new cable.

Use of this new material in the manufacture of a cable gave rise to numerous problems, one of which, namely that of jointing the paragutta, deserves particular mention. In this connection a new technique of jointing was developed which not only produces good joints in paragutta-insulated cable, but also produces better joints in gutta-percha-insulated cable than can be made by the conventional process which has been in general use since the latter were first manufactured.

## Cable Design

Except that it is not loaded, the new cable is similar in type to the 1921 cables. It is provided with copper return tapes ("Transmission Characteristics of the Submarine Cable," Carson and Gilbert, *Jl. of the Franklin Inst.*, v. 192, 1921, p. 705) and also with a thin copper tape under the return tapes for protection against marine organisms. The lay, or pitch, of the return tapes was made much longer ("U. S. Patent No. 1,700,476," Jan. 29, 1929) than in the 1921 cables. This brought about a substantial decrease in the effective resistance of the tapes themselves and reduced the eddy current losses which are due to the helical nature of the return tapes. Thickness of the insulation is much greater ("British Patent No. 343,093," May 7, 1931) compared with the diameter of the central conductor than is the case with low frequency cables, either telephone or telegraph.

In all matters of mechanical design, accepted cable practise was followed. A discussion of some of the mechanical features of cable design as well as some account of the general submarine cable problem has been given in the paper referred to in the first paragraph of this article.

Length of the new cable is 108.6 nautical miles (125.2 statute miles). It was manufactured by the Norddeutsche Seekabelwerke-A.G. of Nordenham, Germany, and laid by its cable steamer "Neptun." The maximum depth attained is 1,080 fathoms (6,480 ft.) as may be seen from Fig. 2. Cross-sections of the various types of cable used at different depths are shown in Fig. 3.

At carrier frequencies the effect of the armor wire is negligible from the standpoints of magnetic modulation and attenuation. Attenuation of the cable (see Fig. 4) is characteristic of a non-loaded cable in that it increases rapidly at low frequencies but less rapidly at high frequencies whereas in general the reverse is true of the loaded cable. Against electrical interference, but little shielding is needed beyond that furnished naturally by the sea water; the small additional shielding required is furnished by a wrought iron pipe enclosing the cable between the cable hut and the level of the lowest tides.

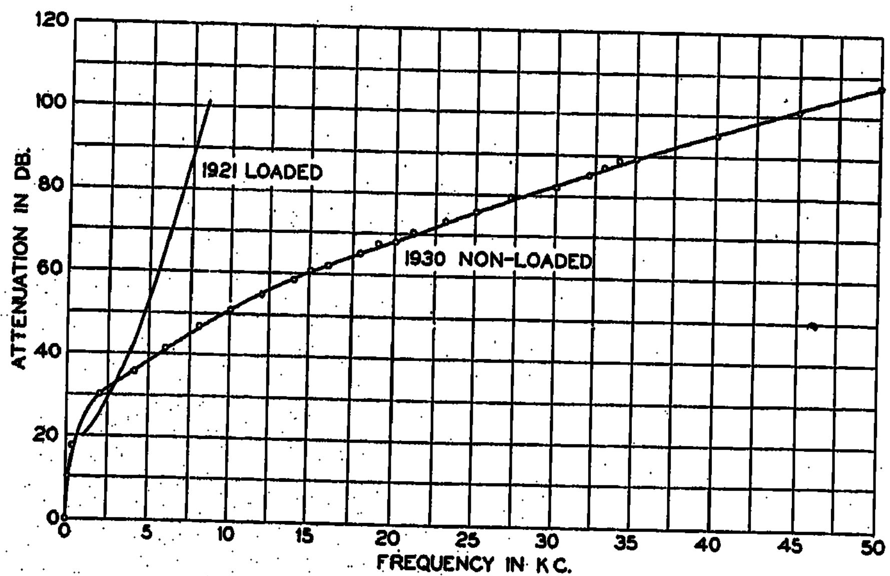

Fig. 4. Frequency-attenuation characteristics of 1921 and 1930 cables

## CARRIER SYSTEM

As noted previously, the three present telephone channels are obtained by an adaptation of carrier apparatus ordinarily used for long distance transmission over open-wire lines ("Carrier Systems on Long Distance Telephone Lines," Affel, Demarest, and Green, A.I.E.E. TRANS., v. 47, 1928, p. 1360-86). Special additional equipment consisting chiefly of receiving amplifiers and directional filters was added to care for the greater gain and selectivity needed to operate over the higher attenuation.

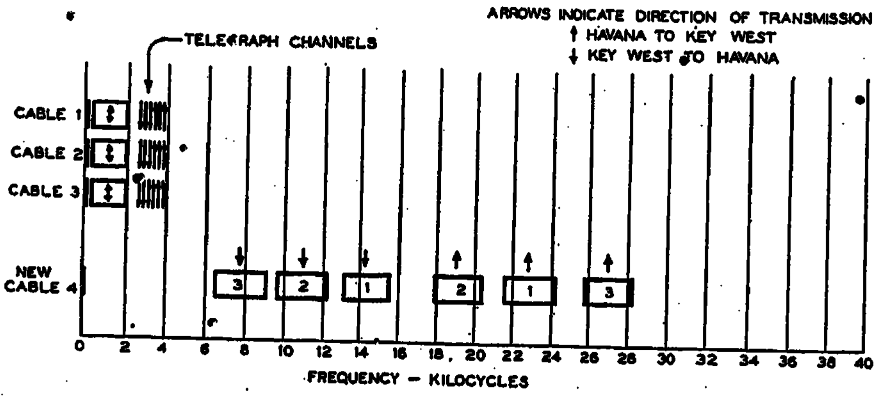

Fig. 5. Frequency allocation of communication channels in Key West-Havana cables

The six frequency bands (one for each direction for the three channels) are allocated as shown in Fig. 5; a d-c. telegraph channel also is indicated. This chart likewise shows the frequency allocation of the one telephone and four telegraph channels (three carrier and one d-c.) now carried over each of the three older cables. It may be noted that the frequency band width of the new telephone channels is much greater than that of the old ones, thus furnishing higher quality speech transmission. In addition, a large range of frequencies remains unused on the new cable; this range may be developed when additional message telephone, broadcasting, or telegraph facilities are needed.

Carrier apparatus is installed in existing telephone offices at Key West and Havana. In each case the office is somewhat over one mile from the cable but at the water's edge. The submarine cable circuit is connected to the apparatus in the offices through pairs of wire in an underground cable of the paper-insulated lead-covered type, which carries also the circuits of the older cables. In Fig. 6 is shown schematically the connections of the apparatus at the Havana end of the cable. The arrangements are practically identical at the two terminals except for differences incident to the fact that different frequency bands are transmitted in the opposite directions.

## SOME TRANSMISSION PROBLEMS

Satisfactory transmission over high cable attenuation involves several especially critical points. First of all, the transmitting amplifier must amplify to the high levels required without modulating sufficiently to produce troublesome new frequencies falling within its own group of frequency bands. New frequencies produced by the amplifier which fall outside of this group are suppressed by directional filters and cause no trouble.

Additional possible sources of modulation are the directional filters and impedance matching transformers; these must transmit the high levels coming from the amplifier but must not modulate them sufficiently to produce troublesome new frequencies falling within the oppositely directed group of bands. The latter are at an exceedingly low level and so the modulation in these circuit elements must be kept extremely small. Some ordinary resistances, mica condensers, and other apparatus,

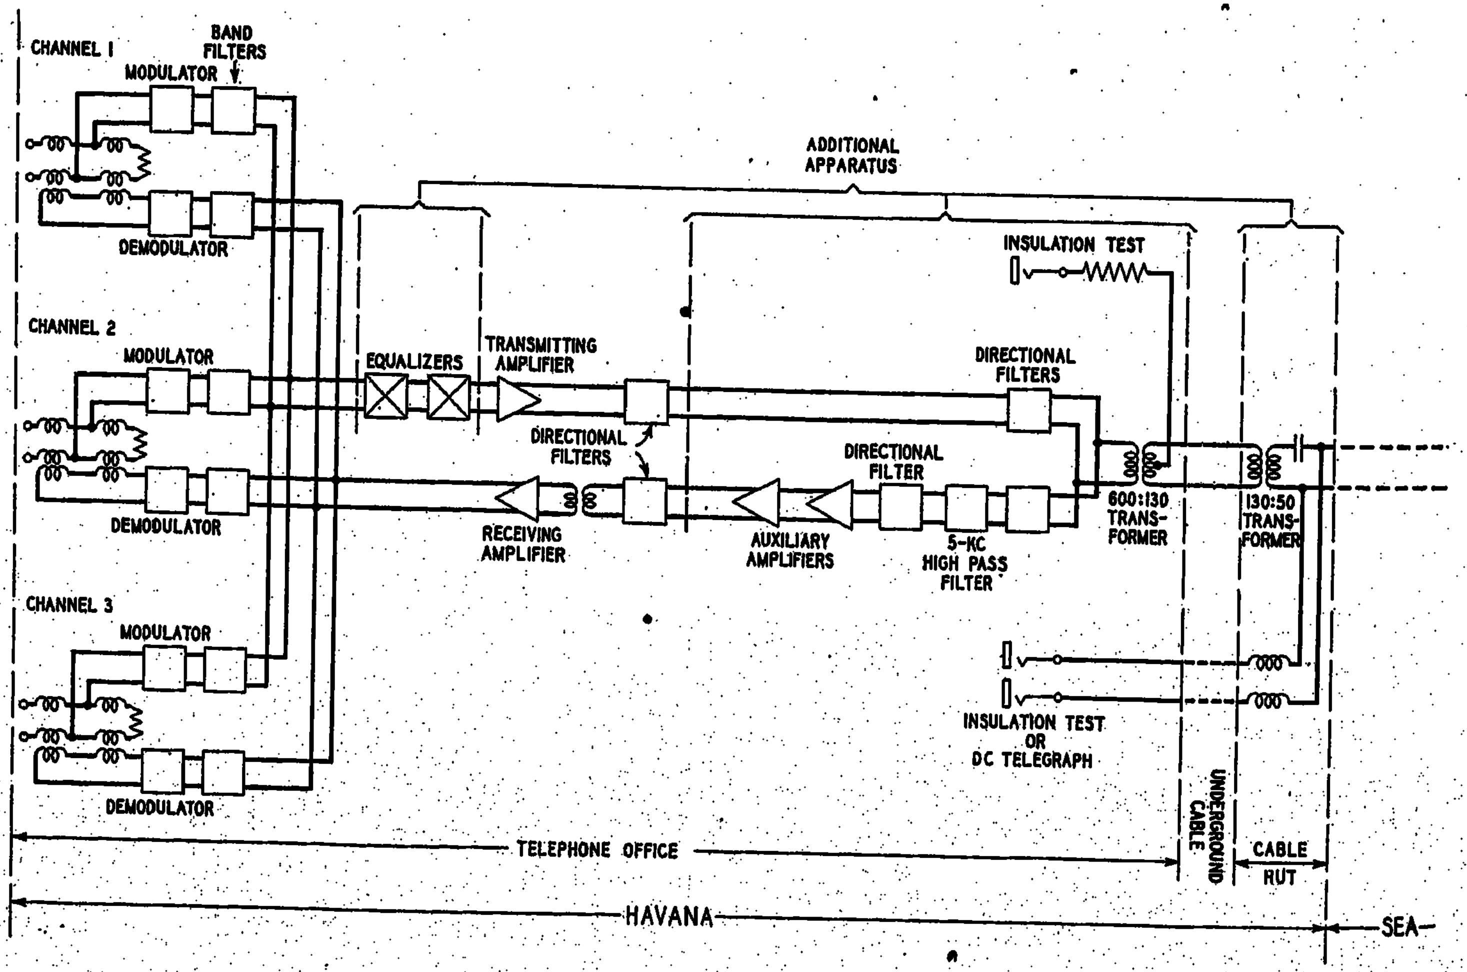

Fig. 6. Schematic diagram of carrier system used on the Havana end of the 1930 cable. Apparatus used on the Key West end is similar except of course it is designed for different frequencies

have been found to have enough modulation to be serious. In this respect ordinary iron core transformers are likely to be extremely troublesome; hence, special design is required to reduce the modulation in the impedance matching transformers to tolerable limits.

NOISE PREVENTION

At the cable ends the important problem naturally is to keep the low level receiving circuit free from interference. In taking the necessary precautions along these lines, many sources of noise were investigated and remedial measures provided. These included cross-talk from other carrier telephone or telegraph systems, high frequency oscillations set up by d-c. telegraph apparatus in the vicinity, radio stations, power wires, submarine telegraph cables, and many minor sources.

Of particular interest was the case where the Commercial Cable Company's submarine telegraph circuits from Havana to New York, a communication facility of low inherent frequency range, interfered with the carrier channels having frequencies up to 28 kc. This interference was found to originate by induction in the underground cable at Havana through which both circuits passed. In this case, by the generous cooperation of the Commercial Cable Company, frequency limiting equipment was added to its cable transmitter.

---

# Electrical Units and Their Application

**Progress and improvement in any art or science are not made without provision for suitable measurements. Many advances in the field of electrical units and their measurements have been scored within the past forty or fifty years. Developments in electrical measurements have been satisfactory in that they have kept slightly ahead of practical demands.**

By
L. T. ROBINSON*
FELLOW A.I.E.E.
General Elec. Co.,
Schenectady, N. Y.

ELECTRICAL UNITS are based upon or definitely related to units of length, mass, and time. In an ordinary sense the latter are not electrical, but because so much depends upon them it is of interest to know how definite and permanent they are; also how precisely they may be determined by reference to existing standards. Of interest also is the accuracy with which copies of the fundamental units may be made, and the degree of precision obtainable in producing for practical use multiples or submultiples of the fundamental unit chosen.

For ordinary work, accuracy of standard and precision of comparison considerably below the best obtainable are satisfactory. Workers in the field of primary reference standards, however, must be able to make determinations from 10 to 100 times more precise than those demanded in practise, so that the practical art has something to grow up to. Nevertheless, unusual practical requirements sometimes arise suddenly that can be met only with precision far greater than any previously employed. It is in this region of high precision that the national laboratories and some independent workers find a highly useful field; and in this class of work the U.S. Bureau of Standards ranks second to none.

For the fundamental units of length, mass, and time, perhaps the most familiar is the so-called c.g.s. system. In this system the centimeter is taken as the unit of length, the gram as the unit of mass, and the second as the unit of time. These units have been quite generally accepted for many years, and are likely to endure for some time to come.

FUNDAMENTAL C.G.S. UNITS

Mass standards are permanent and can be compared with a precision of one, or at least a very few parts in 100,000,000; standards of length are about the same. These therefore lie definitely in the $10^{-8}$ class. (A precision of from 1 to a possible 9 parts in 100,000,000 will be called $10^{-8}$, and so on down to $10^{-2}$.) Time, one of the fundamental elements in many things, hardly can be regarded as in the same class as length and mass. A minimum departure of about 0.001 sec. per day from a uniform rate is required in order that a clock may be included in the $10^{-8}$ class. This is better than has been attained over an extended period of time. The present status of time measurements places it in the $10^{-7}$ class; in fact it even has a tendency to slip into the $10^{-6}$ class.

Roughly 500 years ago the first instruments that really could be called clocks were brought out and were quite definitely in the $10^{-2}$ class, although probably the lower end of this band; in 300 years clocks were brought into the $10^{-6}$ class; and in about 150 years more, into the $10^{-7}$ class. During the

---

Based upon "Electrical Units and Their Application" (No. 31-120) presented at the A.I.E.E. summer convention, Asheville, N. C., June 22-26, 1931.

* Deceased (Nov. 3, 1931).

last few years the clocks of Shortt and of Schuler, each quite different from the other, have given unmistakable signs of being able to qualify for the $10^{-8}$ class. This shows remarkable progress, for twice within about the last 40 years the error in timekeepers has been divided by 10.

This brief consideration of time is not really a digression, for within the last few years the demand for accurate measurement of time on which frequency or wave-length measurements are based came almost too soon. This is a definite example of the precision desired in practical measurements coming too close for comfort to the precision maintainable in primary reference standards.

The time measurement situation, however, is not without its brighter side. The crystal oscillator, which in a certain way caused the trouble by requiring accurate adjustment and timing, has been found to be itself a most reliable timing device. First checked with clocks, it now bids fair to turn about and enter the higher timekeeping class itself. Comparisons between crystal oscillators now can be placed in the $10^{-8}$ class, and timing of crystals in the $10^{-7}$ class.

This brief discussion is of interest because it indicates the present status of units and measurements of the three fundamental standards. The conclusion is that they are in a fairly satisfactory position with time far in the rear, but rapidly advancing to a position of equality with length and mass. Therefore these units form an excellent basis upon which a system of electrical units may be built. Difficulties are experienced, however, in the steps necessary to realize electrical standards from standards of length, mass, and time; no doubt improvements in methods and procedure will be made in time so that the precision assignable to the three fundamental units may be realized more nearly in the electrical units used for fundamental reference.

## ELECTRICAL UNITS

Of primary interest in the field of electrical units are the ohm, the volt, and the ampere, or the absolute units of which these are derived multiples. As may be seen later a wide gap exists between the precision assignable to length, mass, and even time, and that assignable to the absolute values of the practical electrical units. This is so for very good reasons: Fundamental length and mass standards are in a sense arbitrary; this does not give concern because when once established such standards remain permanent within satisfactory limits. In considering electrical units, however, their relation to length, mass, and time must be known; also electrical units must not be arbitrary if agreement with mechanical and other units derived from length, mass, and time is to be maintained. Electrical standards therefore must be kept from change and at the same time must be brought into a definite and predetermined relation to the fundamental units, so that conversion factors may be as simple as possible.

The ohm now is defined as the resistance at 0 deg. cent. of a column of mercury approximately 106.30 cm. in height and having a cross-section of 1 sq. cm. The value of the ohm may be certain to five significant figures ($10^{-4}$) but can hardly be said to be known dependably to six figures ($10^{-5}$). However, work is being done constantly to better this situation. In general, copies and comparisons of resistances may be made to a precision of about $10^{-6}$ with a permanence of primary reference standards of about the same order.

On the basis of the foregoing, the ohm may be considered to be in a fairly satisfactory state of determination, but more certainty as to its absolute value is desirable (at least to a precision of $10^{-6}$). Gratifying progress in this direction has been made. Looking back to the first ohm established by the British Association committee, this unit was about 1.5 per cent smaller than the present ohm. It has taken nearly 50 years to eliminate the greater part of this error, although most of the change was made in one important step. Precision and permanence of the ohm have just about kept out of the way of progress in the practical field.

The volt had a rather bad start; in the early days it was derived primarily from the ampere and the ohm. With much time and care, galvanometers were constructed depending for their accuracy upon measurements of length, and upon the strength of the earth's magnetic field. Here again the unit was tied up with a property of the earth as is the present unit with time; unfortunately, however, amperes cannot be transmitted by telegraphic signal or radio, and although the earth's magnetic field is capable of precise determination, the ampere or multiple of it when realized could not very well be carried home and used. Instruments then were made which did not involve a permanent magnet and which did not depend upon the earth's magnetic field. Some of these electrodynamometers were very good, but were not always dependable or precise within the required limits.

## WESTON CELL AN IMPORTANT ADVANCE

No competitor of the galvanometer or electrodynamometer appeared until the advent of the Clark cell, although certain voltaic cells had been known for some time. The Clark cell could be reproduced in various localities with considerable precision. However, this cell had a marked temperature error, and also was fraught with other difficulties which prevented its general use. The situation regarding the volt was improved enormously, however, when Edward Weston introduced his Standard cell. It was this cell which, in one form or another, now is used, together with copies of the ohm or multiples of either or both, as the basic standard of most electrical measurements. The present status of the volt is such that it is practically in the same class as the ohm, that is the $10^{-4}$ class; as a result the ampere in terms of these two standards may lie perhaps in the same class. This refers to absolute values only; comparisons probably are possible to a precision of about $10^{-6}$.

Using standard cells and carefully compared resistances, a class of instruments has been developed for the determination or realization of ohms, volts, amperes, and watts. These commonly are known as bridges and potentiometers and are capable of giving multiples of the units over a wide range with a precision well up into the $10^{-5}$ class. These instruments are convenient to use and are permanent and reliable; they are employed primarily for the calibration of portable and working instruments. For these purposes, however, the precision of which they are capable is unnecessarily high. Still another class of instruments is represented by the deflection potentiometer, which falls perhaps in the middle part of the $10^{-4}$ class as regards precision.

These instruments may be used both as reference standards and for direct observations. As a result, for continuous currents it is possible at any time to secure definite and accurate measurements which in most cases excel the practical requirements in this respect.

## A-C. MEASUREMENTS

Many measurements must be made where alternating current is the medium; here, in special cases, the instrument commonly used employs some sort of a reflecting device for observing the indications of the moving part. As regards precision these instruments may be placed on the borderline between the $10^{-3}$ and $10^{-4}$ class, but they do not fill the requirements of this class with complete success.

Considering the instruments available for the intermediate class of work (between $10^{-6}$ and $10^{-8}$) of which so much must be done, time and patience surely are taxed to obtain the required results. For this type of work, instruments similar to the deflection potentiometer which would be conveniently usable on alternating current, would be extremely helpful. Another factor which must be considered in this regard is the step from d-c. to a-c. measurements which rests upon the assumption that for the same r.m.s. values, a given instrument will give the same indication on alternating current as it does on direct current. This step does not in all cases rest upon a perfectly secure basis.

## USE OF PORTABLE A-C. INSTRUMENTS

In using portable direct-reading instruments or instruments of the intermediate class on a-c. circuits or systems, it is difficult sometimes to realize the precision of which the instruments are capable. This is because of slow pulsations in the supply source and because all moving systems have not the same time of swing. In addition, a-c. measurements of necessity involve work on rotating machinery and this fact introduces more problems. Some success has been attained by recording photographically or by other means the positions of the pointers of a group of instruments, but this is not always satisfactory; it is usually best to record enough readings to overcome the effects of fluctuations. Although in a well equipped laboratory matters can be improved greatly by using refined regulators on the supply lines, this fills but a small part of the general need.

In dealing with large values of a-c. amperes, volts, and watts, usually it is not possible to employ resistances so precisely comparable with reference standards. In this field it has become customary to employ instrument transformers. These transformers are capable of quite precise work, and when carefully checked and properly used, may be placed in the lower part of the $10^{-4}$ class. Instrument transformers serve the purpose also of protecting the observer from contact with the circuit voltage.

Within comparatively recent years the electrical measurement art has required expansion into the high frequency field and also into the field of very low power-factor measurements; here new requirements are met involving many curious effects which must be guarded against. The recording of wave fronts expressed in microseconds, together with a great variety of problems connected with sound and communication systems using wires and with the radio art, have been met for the most part with a fair degree of satisfaction. This general group cannot be referred to in detail; a tremendous range of voltage, current, power, and frequency must be covered from comparatively small values up to millions of volts, thousands of amperes, and millions of cycles per second.

## OTHER DEVELOPMENTS

Great increases in sensitivity and decreases in the amount of power required to make measurements have been made possible by the use of vacuum tubes; hence a large expansion in this field may be looked for. Permanence and reliability if they could be increased would enhance the usefulness of these methods.

Capacitors or condensers are very useful devices for, when charged with a voltage which can be determined very precisely from standard cells and suitable multiplying arrangements, they are able to give out a definite quantity of electricity. However, condensers are not permanent and reliable to the same extent as resistors and standard cells, and improvements along this line would be desirable. For example, in magnetic measurements it would be much simpler to work from a reference standard condenser than to use mutual inductances determined by some of the well-known methods of comparison, or by direct reference to length standards.

Materials for resistance standards have been improved greatly and at present there appears to be but little need for further improvement. Accuracy with which comparisons can be made is perhaps ten times greater than the precision or permanence of resistance units assembled in practical apparatus without taking undue precautions; such precautions need not be taken if the temperature effects were less than they are now.

Increased development of instruments in the intermediate class ($10^{-4}$) is hoped for; devices are needed which will stand in the a-c. field (at normal and if possible at high frequencies and at low power factor) in the same place that the deflection potentiometer, resistances, and standard cells occupy with respect to d-c. applications.

Among practical workers but little advance has been made along the line of combining and weighing of results, and in the application of well-known and simple probability relations. It is possible to do much along this line; a few simple relations would cover most cases and would be of enormous advantage. Experience can develop an intuitive sense in this regard and if the results obtained with a number of determinations are made use of, and sufficient care taken to control the conditions under which the observations are made, it is surprising what can be done with comparatively crude apparatus.

## SUMMARY

It is not intended that the conclusion to be drawn from this brief review is that conditions regarding electrical units are unsatisfactory. Of course the point of view might be taken that satisfactory progress has not been made in the last 50 years and that the best reference standards are not at all in the same class with available standards of length, mass, and time. Ordinary portable electrical instruments seem crude in comparison with portable and every day instruments for determining mass, length, and time; but the situation should not be regarded at all in this light. Length, mass, and time standards have had at least ten times as long a period of development as have electrical standards.

The one fundamental unit that has advanced the most is time; this advance has been about 100 fold in the past 40 years. Electrical reference standards and the precision of comparison with such standards have been advanced in relation to the fundamental units, by about the same amount in the same length of time. In the portable instrument field and in indicating instruments generally, errors have been divided by about 10 within the same period. Therefore, the situation may be reviewed with some degree of satisfaction. Progress in the field of electrical units has equaled by comparison the rate of progress in other branches, but there is still much to be done and much to be learned by occasional excursions into other lines a little outside of the electrical field. Most important of all, the interest in going forward assuredly is undiminished, and during the next few years further and important advances will be made.

# The Unit of Electrical Resistance

**The mercury ohm, long recognized as a standard of resistance, with its elaborate technique and many disadvantages has become obsolescent. The reasons for this, together with a brief historical sketch of the ohm, are presented in this article.**

By
H. B. BROOKS
FELLOW A.I.E.E.

Bureau of Standards,
Washington, D. C.

IN SPITE OF the vast amount of high class technical labor which has been expended upon the mercury ohm it seems physically impossible to push its limit of reproducibility beyond that attained thirty years ago, namely, a few parts in 100,000. On the other hand, the technique of absolute measurements has improved continuously, until now it is at least on a par with the mercury ohm as regards reproducibility. The technique of absolute measurements undoubtedly can be improved; but even if no better than the present parity (as to reproducibility) with the mercury ohm were maintained, the latter, always a necessary evil, has no further reason for existence. Recognizing these facts the advisory committee on electricity of the International Committee of Weights and Measures, at its 1930 meeting held in Paris, adopted the following resolution:

> "With regard to the unit of resistance, the ohm, considering that methods of determining the absolute ohm are sufficiently advanced and that the agreement between the measurement of the coils (secondary standards) of the different (national) laboratories remains within the limits of precision of the measurements, it is not necessary at present to undertake further comparisons of the resistance coils with mercury ohms."

In order to bring out the full significance of this seemingly radical proposal and the sound reasons for the ultimate abandonment of the mercury ohm as a legalized material standard, a brief historical review of the ohm may be of interest.

## EARLY WIRE STANDARDS

After the announcement by Ohm in 1827 of his famous law, electrical workers began to feel the need for a unit of electrical resistance. As a result several arbitrary standards were suggested by different scientists, these consisting mostly of specified lengths of certain kinds of metallic wire. All of these early proposals, however, were faulty; simple metals were difficult to obtain in sufficient purity, and their resistivity was affected by internal stresses and by the degree of annealing. In addition the alloy wires advocated by some were not of definite or exactly reproducible composition.

---

Based upon "The Unit of Electrical Resistance: Past History and Impending Change" (No. 31-110) presented at the A.I.E.E. summer convention, Asheville, N. C., June 22-26, 1931.

Use of mercury as an ideal metal for an electrical resistance standard seems to have been suggested first by Marie-Davy, but in 1860 Werner Siemens made the first practical proposal concerning it, namely, that the unit of resistance should be "the resistance at 0 deg. cent. of a prism of mercury 1 m. long and 1 sq. mm. in cross-section." He demonstrated that he could reproduce a unit of resistance by means of mercury in glass tubes with an error of less than 5 parts in 10,000. The unit he proposed came into use under the name *Siemens Einheit* (Siemens unit) denoted in the older literature by the abbreviation *S.E.*

In 1861 at the suggestion of Sir William Thomson (later Lord Kelvin) the British Association for the Advancement of Science appointed a committee on standards of electrical resistance. This "B.A." committee as it was known, recognized the necessity for material standards of resistance, but also desired that such standards refer ultimately to an absolute basis; such a material standard when once established was to be regarded as a prototype standard and never to be changed even though succeeding absolute measurements might show it to be appreciably in error. As the absolute basis upon which to establish the proposed standard, the committee finally adopted the centimeter-gram-second, or ordinary c.g.s. system.

### B.A. UNIT ESTABLISHED

Three members of the B.A. committee in 1863 and 1864 made absolute measurements of resistance at King's College, by rotating a short-circuited coil of copper wire about a vertical diameter and with a measured velocity, observing the resulting deflection of a magnetic needle at the center of the coil. From the known angular velocity, the deflection of the magnet, and the linear measurements of the coil, the resistance of the coil was computed in absolute units. Upon the basis of this work, the committee constructed standard coils of platinum-silver wire, and began to issue copies of the "B.A. Unit." The committee was dissolved in 1870, but in 1878 the investigations of Rowland at Baltimore showed that the B.A. unit was more than 1 per cent smaller than the value ($10^9$ c.g.s. electromagnetic units) which the committee had intended to give it. This result was verified soon afterward by other investigators, and in 1880 the B.A. committee was reappointed.

In the meantime several mercury standards of resistance had been set up in accordance with the proposal of Werner Siemens. From the standpoint of that time, agreement between these standards was satisfactory and the results of absolute determinations consequently had been referred directly or indirectly to the Siemens Unit.

### EARLY ATTEMPTS TO LEGALIZE THE MERCURY OHM

In 1881 an International Congress of Electricians met at Paris for the purpose of establishing definitions of the electrical units in a form suitable for enactment into legislation. This congress adopted a resolution proposing: that the ohm preserve its previous definition, namely, $10^9$ c.g.s. electromagnetic units; that it be represented by a column of mercury 1 sq. mm. in cross-section, at a temperature of 0 deg. cent.; and that an international commission be charged with the determination, by new experiments, of the length of the mercury column to have a resistance of $10^9$ c.g.s. electromagnetic units. At its second meeting, held at Paris in 1884, this commission known as the International Conference for the Determination of the Electrical Units, adopted 106 cm. as the length of the mercury column, in spite of the fact that the best absolute determinations indicated 106.3 cm. to be more nearly correct. This compromise with the facts was made because it was considered advisable for a provisional value to be correct to the last figure given. The unit of resistance so defined was given the misleading name *legal ohm*, but although it was used to some extent, it was never legalized.

The B.A. committee mentioned previously continued its work during the next succeeding few years, adopting the legal ohm in its standardizing work with a supplementary statement of the value of the legal ohm in B.A. units. In 1892, however, this committee discontinued issuing standards in terms of the legal ohm in favor of the ohm defined as a resistance of a column of mercury 106.3 cm. long. In the meantime this committee had experienced difficulties from variations in the relative values of its wire standards. These difficulties effectually negatived the committee's original plan for a wire standard never to be altered, and established the fact that some independent and reliable method for checking the constancy of the wire standards was required.

### MERCURY OHM ADOPTED INTERNATIONALLY

Another important development came about during the Chicago Exposition of 1893, when an international electrical congress met with representatives of ten governments in attendance. This congress adopted resolutions defining eight electrical units, and to distinguish them from their predecessors these units were called *international* units. The international ohm was defined as being based upon $10^9$ c.g.s. units of resistance, and as represented by the resistance offered to an unvarying electric current by a column of mercury 14.4521 g. in mass at the temperature of melting ice, having a length of 106.3 cm. and a constant cross-sectional area.

Because of certain defects and inconsistencies in the resolutions of the Chicago congress, the six national governments which afterward legislated on the matter defined the electrical units in different ways. One of the outstanding defects of the Chicago resolutions was that the ohm, ampere, and volt, which are physically related by Ohm's law, all were defined in terms of material standards.

The next international congress on electrical units and standards was held in 1908 at London, with delegates from 21 countries. At this meeting resolutions were adopted which for the first time clearly differentiated between the fundamental (absolute) electrical units, and a system of units representing the fundamental units, and sufficiently near them for practical use and to serve as a basis for legislation. Recommendations made by this conference, however, did not affect the value of the ohm; hence the international unit of resistance remained as defined at the Chicago exposition congress of 1893, and has not been altered since that time.

Time and patience required in making mercury ohm determinations are so great, however, that in spite of its legal standing, only a relatively small number of outstanding determinations have been made during the past thirty years. The elaborate technique of cleaning, calibrating, and cutting off the tubes, measuring their length, determining the mass of contained mercury, and of comparing the resistances of the tubes with existing wire standards, is too laborious and involved to be outlined here. To be worth doing at all, this technique must be carried out by scientific men of great manipulative ability, with the observance of extreme precautions against errors in various parts of the measurement.

## Advantages and Disadvantages of Mercury Ohm

Principal advantages of the mercury-ohm standard are as follows: The conducting material is free from internal molecular stresses and is purifiable to a high degree. Because it can be reproduced from specifications, the mercury-ohm standard serves to record the unit of resistance of any given period within a few parts in 100,000 for future reference. The standard is simple in construction, but for many years its numerous drawbacks have caused it to be much neglected, even in countries which have legalized it.

Disadvantages of the mercury-ohm standard are: The conducting material has a high temperature coefficient of resistance, which in conjunction with the high thermal resistivity of glass makes it difficult to measure the temperature of the mercury with sufficient exactness and limits the allowable test current through the mercury column to a small value. It is known now that mercury is not a simple substance, but a mixture of isotopes. (This is not a serious objection from the practical standpoint, because the particular mixture of isotopes of mercury found in nature seems to be very closely the same everywhere.) The mercury is liable to slight contamination from the metal electrodes immersed in it. Glass tubes cannot be made straight and of uniform bore, and the error arising from waviness of the bore, though of known sign, is of indeterminable magnitude. Terminal bulbs which are necessary to make connection to the ends of the mercury column introduce an uncertainty because as yet no method has been found for definitely calculating the terminal resistance with sufficient accuracy; this makes it necessary to adopt an empirically chosen size of end bulb. The wires which lead the current into the terminal bulbs must be small so as to minimize the conduction of heat to the mercury; they are therefore of relatively high resistance, which is a drawback in some methods of effecting electrical comparisons.

It may be of interest to summarize some of the other major reasons for the original adoption of the mercury ohm and its present obsolescence. The mercury ohm originally was proposed at a time when electrical workers were isolated. Existing means of communication were slow and imperfect, and hence each worker felt the need of preparing his own standards. Although the underlying absolute electrical units were recognized from the beginning of the B.A. committee's work, the crudities of apparatus and technique of absolute measurements resulted in such a scattering of values obtained, as to constitute an imperative reason for a physical standard of resistance reproducible from specifications.

The situation has altered greatly since the beginning of the present century. The day of the isolated worker, setting up his own standards, has passed, and now great national standardizing laboratories not only establish standards with an accuracy beyond the resources of most individual workers, but have a legal status which gives the stamp of authority to their certified values. By the exchange of standards, these national laboratories keep in touch with one another, thus securing a measure of international uniformity.

## Absolute Measurements

It is beyond the scope of this article to give more than the briefest reference to absolute measurements. The spinning coil of the B.A. committee already has been mentioned. The Lorenz apparatus is an elementary dynamo in which a non-magnetic metallic disk is rotated within the magnetic field of two solenoids wound on non-magnetic cores and traversed by a steady direct current from an external source. The apparatus thus constitutes a sort of homopolar generator in which an e.m.f. is induced radially in the rotating disk. At a certain definite speed, this induced e.m.f. will just balance the *IR* drop between the potential terminals of a four-terminal resistance standard through which passes the steady current circulating in the solenoids. From the accurately determined speed of rotation, and from mechanical measurements of the dimensions of the disk and of the field coils, the resistance of the standard between its potential terminals can be calculated in terms of the c.g.s. absolute electromagnetic unit. The most outstanding Lorenz apparatus built thus far is that at the British National Physical Laboratory.

An absolute apparatus, simpler in some respects, is used at the German Reichsanstalt and at the United States Bureau of Standards. It employs single-layer solenoids wound upon accurately machined cylindrical forms of non-magnetic material such as marble. In terms of the fundamental units, the self-inductance of such a coil can be computed with high accuracy from measurements of its dimensions. The self-inductance also can be measured in terms of the international ohm and the second of time by means of a-c. methods, using currents of which the frequency is known accurately. From the two results may be derived the ratio of the international henry to the absolute henry ($10^9$ c.g.s. units of inductance). It may be shown that this ratio, which is 1.00052 plus or minus a few units in the last place, is also the ratio of the international ohm to the absolute ohm. Results obtained by this a-c. method are in close agreement with those obtained with the Lorenz apparatus.

### Legalized Standards Needed

It would be premature to attempt to set even an approximate date for the establishment of the absolute electrical units on a *legalized* basis, but there are urgent reasons for reaching this goal as soon as possible. Rapid development of electrical technology in recent years has imposed new and exacting demands for accuracy of measurement and permanency of standards. Nowhere is this demand more impressive than in some phases of the radio art where for example frequency measurements are carried out and standards of frequency have been developed to an accuracy so great (a few parts in ten million) as to threaten to expose the failings of even the most highly developed timekeepers used in observatories. The world-wide sweep of radio makes international uniformity of frequency standards an imperative necessity.

Electrical standards of various kinds, embodying errors known to exist in the present units, are being made and distributed more widely than ever. This is an added incentive toward legalization of absolute units, for the longer such action is deferred, the more costly and troublesome will be the necessary readjustment of the standards used in engineering and science when such legalization ultimately is accomplished.

# International Standard of Electromotive Force

**Although unremitting care must be exercised in their manufacture and handling, cadmium cells have proved to be convenient and reliable sources of standard e.m.f. Principal characteristics of these units and precautions to be observed in their use are pointed out in this article.**

By
MARION EPPLEY
MEMBER A.I.E.E.

Eppley Research Lab.,
Newport, R. I.

THE INTERNATIONAL VOLT is defined in terms of the mercury ohm and the silver voltameter. This combination, in addition to being unsuitable for routine work, requires that an unchanging potential drop be maintained across the standard ohm which in turn demands that a source of constant e.m.f. be available to maintain a constant current through the voltameter. Such a source of constant e.m.f. when so used undergoes calibration and thus may become useful as a standard of e.m.f. without combination with the voltameter and the ohm. If such sources are to serve as primary standards, for convenience they should be reproducible.

In practise, galvanic cells provide serviceable standard sources of e.m.f., and are known as *standard cells* when they fulfil the necessary requirements. Two general types of construction are to be had, namely, the portable form in which the constituents are kept in place by a plug or septum of porous material, and the non-portable type without a septum, gravity holding the constituents in place. Generally the container is a glass vessel made of tubing in the form of an H.

In addition to this purely physical distinction in standard cells, there is a more fundamental difference between *normal* or *saturated* cells and *unsaturated* cells. The normal cell contains an excess of the salt of the electrolyte, and it is reproducible at all temperatures within its range. The unsaturated cell has an electrolyte saturated at some temperature below the customary range of room temperatures. Therefore, due to difficulties of technique, the unsaturated cell is not reproducible. However, it is constant in e.m.f. and has a lower temperature coefficient than does the normal cell. Temperature coefficient of the unsaturated cell can be taken as less than −0.00001 volt per deg. cent.; hence, though the normal or saturated cell makes the best primary standard, the best laboratory standard is the unsaturated cell calibrated against the normal cell, the latter in turn having a value based upon the ohm and the voltameter.

### Weston Introduced Cadmium Cell in 1893

Although several different standard cell systems have been introduced, all except one now are of historic interest only. The specific system in general use today is that proposed by Dr. Edward Weston; its unsaturated form was patented by him in 1893, and consists of mercury-mercurous sulphate-aqueous solution of cadmium sulphate-cadmium amalgam. In his honor, the two types of this cell are known, respectively, as the normal Weston cell or the

---

Based upon "International Standard of Electromotive Force and Its Low-Temperature-Coefficient Form" (No. 31-121) presented at the A.I.E.E. summer convention, Asheville, N. C., June 22–26, 1931.

saturated Weston cell, and as the unsaturated Weston cell or simply the Weston cell. These cells are known also as the cadmium cells, the terms cadmium cell and Weston cell being synonymous as applied to the composition of the system, but the latter requiring no further qualification to denote that it specifies an unsaturated element.

Materials used in cells require careful chemical treatment. Mercurous sulphate is particularly sensitive, but when mixed with finely divided mercury can be prepared by electrolysis; this is the best preparation found so far. Cadmium sulphate would seem to require more rigorous purification than it has received at the hands of many investigators in the past, more especially to eliminate salts of manganese. Mercury must be redistilled after washing in acid, and only the purest cadmium must be used.

### Use of Standard Cells

Since current should not be drawn from standard cells when making comparisons against such units, only a null-point or compensation method should be used; some form of potentiometer provides this. ("A Simple Direct-Reading Potentiometer for Standard Cell Comparisons," Eppley & Gray, *Jl. Opt. Soc. Am.*, v. 6, 1922, No. 8, p. 859–64, and "An Improved Fuessher Type Potentiometer," Eppley & Gray, *Rev. Sci. Inst.*, v. 2, 1931, No. 4, p. 242–9.) Usually the entire e.m.f. of the cell used as standard is compared against the entire e.m.f. of the cell being checked; in this method the potential drop in the potentiometer acts as a transfer-standard. This drop must be kept constant, so that it is well to lag the storage cell (which furnishes the potentiometer current) with heat-insulating material to prevent changes in room temperature from causing fluctuations in the measuring current, or potential drop. For best results, accumulators should be kept on a stand above the floor in order to avoid drafts. With this precaution, and by shifting from standard to unknown several times with readjustment of the measuring current if necessary and the attainment of a new balance with the unknown, results can be obtained with a potentiometer of proper design that will be reproducible from day to day within 6 microvolts. Furthermore, this method has the convenience of being direct-reading.

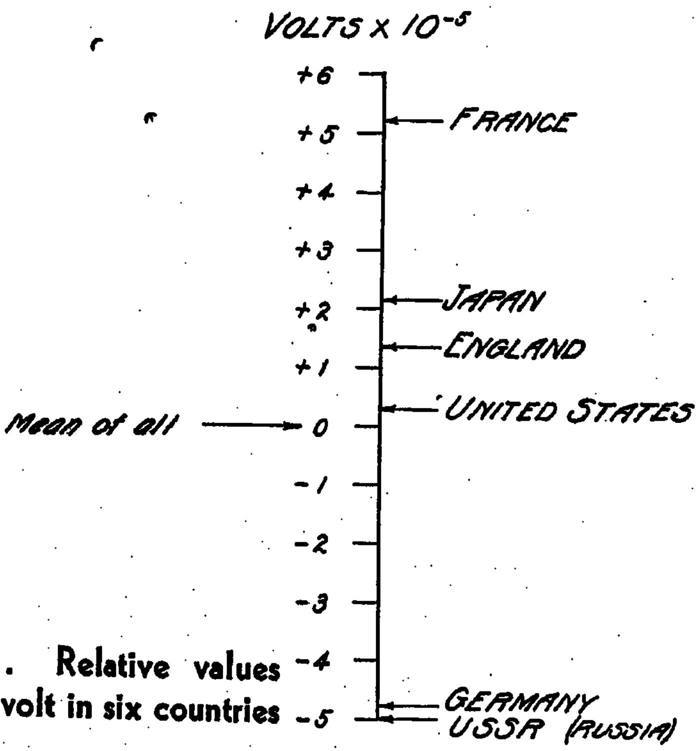

**Fig. 1. Relative values of the volt in six countries**

By Vinal, *Trans.* Am. Electrochemical Soc., 54, 251 (1928) Fig. 1

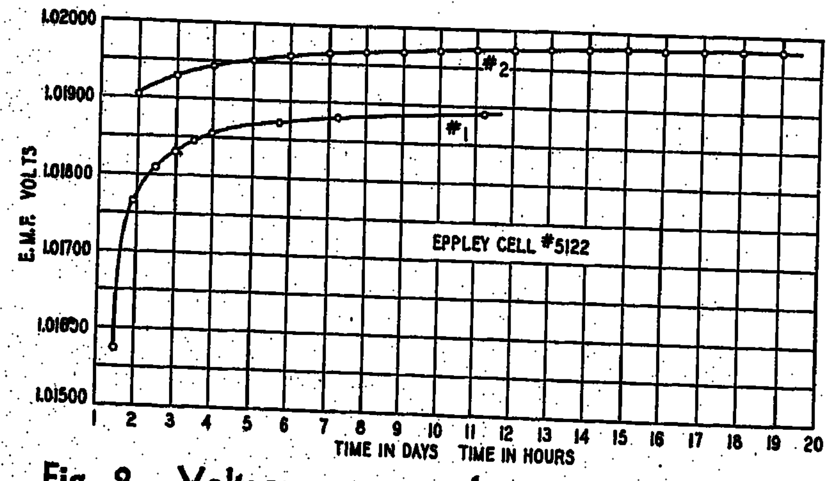

**Fig. 2. Voltage recovery of an unsaturated cadmium cell after 30-min. short circuit**

Curve 1—voltage vs. hours for first day
Curve 2—voltage vs. days from second day
Volts before short circuit—1.019875
Volts after 36 days' recovery—1.019800

One disadvantage of the method just described, though perhaps more theoretical than real, is that the standard and the unknown are not compared at the same instant. For measurements beyond criticism, therefore, it is best to oppose the unknown and the standard, reading the difference in e.m.f. on a potentiometer or by some other suitable means. This reduces to a minimum the effect of fluctuations in the measuring current, and makes use of only one or two dials of the potentiometer with a corresponding reduction in the number of corrections to be applied. This method is not direct-reading, however, and the sign of the residual must be watched carefully. Whatever method be used, the measuring current must be made such that it will have come to a steady state. Careful attention should be given also to shielding the installation against stray leakage currents.

### Voltage of the Weston Cell

Looking forward to its ultimate use as the international standard of e.m.f. in place of the Clark cell, the London International Electrical Congress in 1908 adopted specifications for the Weston normal cell provisionally fixing its e.m.f. at 1.0184 international volts at 20 deg. cent. On January 1, 1911, however, after much experimentation by the International Technical Committee (composed of delegates from the national standardizing laboratories of Great Britain, France, Germany, and the United States) the e.m.f. of the normal cadmium cell was adopted by the Bureau of Standards as 1.01830 volts at 20 deg. cent. for the United States. During the interval 1924 to 1928, the reference cell at the Bureau of Standards has agreed to within 8 microvolts with the mean of the primary reference group (a group of 36 cells left at the Bureau by delegates of the International Technical Committee). The value of e.m.f. at the Bureau of Standards is about 3 microvolts higher than the mean of the values of the cells maintained in France, Japan, England, the United States, Germany, and the U.S.S.R. (See Fig. 1.)

All cadmium cells show a temperature hysteresis of e.m.f.; although this can be made very small, it still exists. Hence cells should not be subjected to sudden changes of temperature. Cooling from 30 to 25 deg. cent. in 70 min. caused a divergence of 0.02 per cent in one group and 0.027 per cent in two groups of cells respectively, the basic value being the mean of the e.m.f.'s obtained before the cells were run through a temperature cycle from 15 to 50 deg. cent. and back to 25 deg. cent. as above.

Unsaturated or Weston cells show a drop in e.m.f. of about 0.003 per cent per annum, so that for an accuracy of 0.01 per cent they should be recertified at least once every two years. This drop is explained best by the diffusion of mercurous ions to the amalgam face where it is discharged, mercury depositing out and cadmium going into solution; this increases the cadmium concentration of the electrolyte with a resultant drop in e.m.f. When the concentration of the normal or saturated cell is reached, the e.m.f. should remain constant at 1.01830 volts at 20 deg. cent., but an increase in the temperature coefficient will have been brought about. Some cells drop in e.m.f. more rapidly than 0.003 per cent per annum, and do not come to a constant e.m.f. when the value of the saturated cell is reached; this is due to the systems not having been set up properly. Such cells usually show marked hysteresis effects when subjected to temperature changes, and should be discarded accordingly.

### CARE AND HANDLING OF CELLS

Cells should not be short-circuited as this is likely to upset permanently the original equilibrium of the electrolyte. In a special test three cells short-circuited for ten minutes required seven hours to return to within 0.02 per cent of their original values. (See Fig. 2.) Furthermore, it is best never to draw more than 0.0001 ampere from a cell even if the circuit is closed momentarily only.

Cells should not be exposed to heat even as much as that radiating from an electric light bulb. Such heating, when greater on one side of a cell than on the other, has given rise in unmounted cells to variations of from 0.01 per cent to 0.02 per cent, even though the lamp was rated at only 25 watts and was 15 in. away from one leg of cells. (The exposure was for five minutes only.) Similar effects have been observed in cells mounted in molded cases. Drafts as well as heating due to handling also should be avoided.

Shaking seems to have no effect upon properly made portable cells, provided it is neither too vigorous nor too long. However, after a cell has been shipped, it is better, as a safety measure, to let it stand for two or three days at least before placing reliance upon it.

If an accuracy of at least 0.02 per cent is wished, cells should not be used at temperatures below 15 deg. cent., although even freezing in some cases has seemed to have had no permanently injurious effect. Recovery from cooling, say to about 12 deg. cent., is rapid requiring only an hour or so at the most to restore the proper e.m.f.

This brief discussion may have raised doubts as to the reliability of the cadmium cell as a standard of e.m.f. It is true that the cell is by no means foolproof, but few precision devices are. Ceaseless care must be given to its manufacture, and a thorough knowledge of its chemistry gained in order to insure the maximum of constancy and agreement. Nevertheless, there are few if any other electrical measurements in which so high a precision (0.01 per cent) can be secured with so few precautions as in the determination of e.m.f. by means of a standard cell and some form of potentiometer.

---

# Recent Developments in Magnetic Units

**To overcome confusion in the use of electromagnetic units, the International Electrotechnical Commission through its subcommittee on electric and magnetic magnitudes and units has been working for several years toward standardization in definition and nomenclature. In this article, recent actions in that direction are discussed and a brief summary of earlier contingent actions is given.**

By
A. E. KENNELLY
FELLOW A.I.E.E.

Harvard University
Cambridge, Mass.

EXAMINATION of the technical literature of the magnetic circuit during the past 30 years shows much ambiguity and misunderstanding among writers in all parts of the world, as to the definition and meaning of the magnitudes of units in general use. In particular, the name "gauss" has been used by some writers for the c.g.s. unit of magnetizing force $H$, by others for the c.g.s. unit of magnetic flux density $B$, and by still others for both $H$ and $B$ indiscriminately. Moreover, the important and much used quantity permeability $\mu$, admittedly defined as the ratio $B/H$, has been regarded by some as having physical dimensions, and by others as having zero dimensions or as being a mere numeric. This confusion

---

Prepared especially for ELECTRICAL ENGINEERING and based in part upon the minutes of the London 1931 meeting of the International Electrotechnical Commission held September 18, 1931. *Not published in pamphlet form.*

of definitions apparently has pervaded the literature of all countries. It gives rise to much misunderstanding and perplexity in the study of either basic or applied magnetism. These differences of thought and expression are found in text-books both of physics and of electrical engineering. It is this confusion brought about in electrotechnical literature that is the main source of complaint.

From a practical standpoint, the underlying philosophy of the electromagnetic field is of lesser importance than the arithmetical meaning of the formulas necessarily used in engineering; hence the urgency of international agreement upon the definitions involved, even though it may be admitted that these rest upon mere conventions. This brief and unofficial account of efforts to arrive at such agreement may be of service to readers of electrotechnical journals who may not have been fully informed of what the International Electrotechnical Commission already has been able to accomplish in this direction. It is hoped also that the article may be of value even to those who may read the official minutes, but who are not fully acquainted with the subject's history.

## SUMMARY OF EARLIER ACTIONS IN MAGNETIC UNITOLOGY

At the I.E.C. plenary meeting of 1927, in Bellagio, a proposal was introduced to adopt a unit of magnetic flux $\Phi$ in the practical or volt-ampere-ohm series of units. After discussion, this was referred for consideration and report to a special subcommittee of seven members representing as many different national committees. This subcommittee was unable to reach agreement, but recommended that the questions be studied by all the national committees and be brought up for discussion at the next plenary meeting of the I.E.C., set for 1930 in Scandinavia. (See "Magnetic Circuit Units," A. E. Kennelly, A.I.E.E. TRANS., v. 49, 1930, p. 486-93.)

Accordingly, the subcommittee on magnetic units convened at the 1930 meeting in Scandinavia. Its membership was increased to include twelve countries, and its name was changed to Section B of I.E.C. Advisory Committee No. 1 (nomenclature) on Electric and Magnetic Magnitudes and Units, hereafter referred to as the E.M.M.U. subcommittee.

During June and July 1930 the E.M.M.U. subcommittee held several meetings at Stockholm. Its first action was to agree unanimously on the convention that inasmuch as flux density $B$ and magnetizing force $H$, in free space have different physical dimensions; their ratio $\mu_0$ (space permeability) is a dimensional quantity and not a mere numeric unit. Also it was agreed unanimously that $\mu/\mu_0$, the ratio of the absolute permeability of a magnetic substance to space permeability, should be called its relative permeability and should be taken as a pure numeric. (See "Magnetic Circuit Units Adopted by I.E.C.," A. E. Kennelly, ELECTRICAL ENGINEERING, v. 50, 1931, p. 133.)

After disposing of this permeability question, the E.M.M.U. subcommittee next adopted the names for four c.g.s. magnetic units, either unanimously or by a large majority. These are given in Table I.

**Table I—C. G. S. Magnetic Units Adopted at Oslo in 1930 and Reendorsed at London in 1931**

| Unit | Symbol | Name |
|---|---|---|
| Magnetomotive force | $\mathcal{F}$ | gilbert |
| Magnetizing force | $H$† | oersted |
| Magnetic flux | $\Phi$ | *maxwell |
| Flux density | $B$† | gauss |

*The name "maxwell" had been adopted at Paris in 1900, with the same meaning.

†Script symbols $\mathcal{B}$ and $\mathcal{H}$ sometimes are used, but because of their convenience italic capitals as shown above are recommended.

The name "oersted" had been used in America for the c.g.s. unit of reluctance $\mathcal{R}$ but had not been adopted internationally. It was transferred to the unit of $H$, on the proposal of the Danish committee, partly because Oersted's discovery of 1820 related to $H$ and not to $\mathcal{R}$, and partly to indicate that "gauss" was considered inapplicable to $H$, after having been assigned to $B$ because of their accepted difference of dimensions.

In addition to the foregoing, the E.M.M.U. subcommittee adopted at Stockholm the practical unit of magnetic flux $\Phi$ with the value of $10^8$ maxwells, and with the name *pramaxwell*. It was agreed also to adopt the prefix "pra" as applicable to deriving practical units from corresponding c.g.s. units. Other actions taken concerned reactive power and power factors in a.-c. circuits. These have not been subjected to serious criticism since the Stockholm meeting and already have been adopted, at least to some extent, in various countries. They all are duly set forth in I.E.C. *document R.M.77* (French and English texts).

All of the actions mentioned were reported and unanimously approved at the I.E.C. plenary meeting in Oslo on July 9, 1930.

## EVENTS OCCURRING BETWEEN 1930 AND 1931

Actions taken in 1930 at Oslo regarding magnetic units gave rise to a great deal of discussion in electrotechnical journals throughout the world, and particularly in the pages of the *Revue Générale de l'Electricité*. Criticism centered mainly about two points: That the names of savants should not have been given to units inthe c.g.s. system, but should have been reserved for units in the practical system; and that the name "gauss" should not have been given to the unit of flux density $B$, but to that of magnetizing force $H$, in conformity with established usage in magnetic observatories.

Regarding the first objection, it has been pointed out that although up to and including the year 1893, the date of the Chicago international congress, names of savants were assigned exclusively to practical units, yet owing to the decisions of the Chicago congress that magnetic units should be kept within the c.g.s. system, the names "gauss" and "maxwell" were given purposely at the Paris congress in 1900, to c.g.s. magnetic units. Therefore, the I.E.C. meeting at Oslo merely followed the actions taken at Paris. It has been pointed out also that the earth's magnetic field has been recorded for many years in gauss or gammas of $10^{-5}$ gauss, yet this field always is measured in air, a feebly magnetizable medium; what actually is determined is a terrestrial flux density $B$ in the air. Consequently, although from a practical standpoint the numerical difference between $H$ and $B$ in air may be insignificant, yet no error in principle is created by speaking of the earth's field in gammas referring to $B$.

In view of the differences of opinion elicited by the publication of the decisions reached at Oslo, arrangements were made and announced early in 1931 to all the national committees, for holding a meeting of the E.M.M.U. subcommittee at London in September 1931.

## NEW COMMITTEE ESTABLISHED

In July 1931, the International Union of Pure and Applied Physics met at Brussels and for the first time established an international committee on "Symbols, Units, and Nomenclature" (S.U.N.). This committee elected as its chairman, Sir Richard Glazebrook, and as secretary, Dr. E. Griffiths. Since electrotechnical units fall within the scope of the S.U.N. committee, the members of that committee were invited to attend and participate in the London meeting of the E.M.M.U. subcommittee on September 18, 1931. The chairman and secretary of the S.U.N. committee were able to accept and took part in the meeting, as also the general secretary of the International Physical Union, Prof. H. A. Abraham.

## ACTIONS AT THE LONDON MEETING IN 1931

National committees of ten countries were represented at the opening E.M.M.U. subcommittee meeting in London on September 18, 1931; countries represented were: Denmark, France, Germany, Great Britain, Holland, Italy, Norway, Poland, Sweden, and U.S.A. Proposals considered and actions taken are reviewed briefly in the following paragraphs.

1. A proposal "that the c.g.s. magnetic units and their accepted names as fixed at the Oslo plenary meeting should remain undisturbed." This proposal was voted unanimously, two countries, however, abstaining (Holland and Italy).

2. A proposal relating to a series of practical magnetic units, based upon the volt-second or "pra-" system as adopted at the Stockholm meeting, with the ampere-turn as unit of m.m.f. After a lengthy discussion, during which considerable difference of opinion was revealed, it was unanimously voted to defer action on these practical units until the national committees should have had further opportunity for investigation; however, on the particular question of a practical unit of magnetomotive force $\mathfrak{F}$, and whether a coil of $N$ turns, carrying a steady current of $I$ amperes, should be taken as $\mathfrak{F} = 4\pi NI$ units or merely $\mathfrak{F} = NI$, a vote was called for, on the proposition that it should be the former. Three countries were in favor of the proposal (France, Holland, and Italy) while four voted against it (Germany, Great Britain, Sweden, and U.S.A.); two countries (Norway and Poland) abstained from voting. It is evident that there is much difference of international opinion over this important question.

3. Conventional interpretation of reactive power in unspecified a-c. right-angled power diagrams. The question considered was whether + *j vars* should be taken as signifying inductively reactive power or the reverse when the basis of the diagram is not specified. It was voted unanimously that a convention be adopted, but that decision as to direction be deferred until a new and definite American recommendation should be presented. Some difference of opinion had been raised as to whether the particular direction recommended ($+jP_r$ for inductively reactive power) was the more advantageous choice.

4. Proposed international adoption of the prefixes "ab" and "stat" applied to a practical unit, for the designation of a corresponding unit in the c.g.s. magnetic or in the c.g.s. electrostatic system, respectively. These prefixes have been and are in use to some extent in America, but never have been adopted internationally. For lack of support to the proposal, no action was taken.

At the conclusion of the foregoing considerations it was unanimously voted to ask the central I.E.C. office to invite the cooperation of the International Physical Union to participate in the formation of a joint committee to consider the question of the electrotechnical units under discussion. It was the general hope that there might be close cooperation in the future between the two organizations on all questions in which physics and electrotechnics jointly are involved.

## RESULTS OF THE LONDON MEETING OF 1931

Consequences of the London meeting of the E.M.M.U. subcommittee may be of far-reaching international importance in electrotechnics if they serve, as apparently they should, to terminate the confusion in the use of the c.g.s. magnetic units which has existed in the literature of electromagnetic engineering throughout the world for at least 30 years. The series of names and definitions for these units adopted in 1930 during the plenary meeting at Oslo has been discussed openly in many countries for more than a year, and these were reendorsed without opposition at the London meeting. It is to be hoped therefore that the units as adopted will come into general electrotechnical use.

There remain at least four c.g.s. magnetic units that as yet have received no names (permeance, permeability, reluctance, and reluctivity); but the four units to which definitions and names have been given (see Table I) probably are sufficient for present practical purposes. These are based upon the convention that space permeability is more than a mere number. There remain a certain minority of both physicists and engineers who disagree with that convention; but after so many years of ambiguous reading and writing it would be strange indeed if an immediate unanimity on this difficult question could be obtained in every country. It can only be hoped that a harmonious procedure through international convention will be secured, and this the recent London meeting has endorsed.

From a philosophical point of view, it is curious that the London endorsement of the I.E.C. Oslo action on magnetic units and their underlying convention should have been almost coincident with the London Faraday celebration of 1931. It is admitted generally that Faraday's researches made magnetic flux in space the salient phenomenon in magnetics, whereas the magnetic pole or quantity of magnetism on a polar surface previously had been the dominating concept. It has been suggested that the modern change in underlying convention reflected in the I.E.C. actions may be attributable to the change in views resulting from Faraday's work.

As for the series of practical magnetic units introduced by the adoption at Oslo of the *pramaxwell*, the whole question is to be discussed further by the national committees of the I.E.C. in cooperation, it is to be hoped, with the International Physical Union before proceeding further in that direction. For the present, we may remain well content to work with the c.g.s. system.

# Summer Convention Offers Attractive Program

FOR THE 48th annual summer convention of the A.I.E.E. to be held at Cleveland, Ohio, June 20–24, 1932, the Cleveland national convention committee has planned a program of entertainment, inspection trips, and recreation, supplementing the excellent technical sessions, all of which should cause this convention to be attractive as a vacation as well as of benefit professionally. Convention headquarters will be at the Hotel Cleveland, located on the Public Square of the city.

### TECHNICAL SESSIONS

Many papers covering a wide variety of interesting subjects in the field of electrical engineering will be presented in nine technical sessions scheduled during the week of the convention. Two of the sessions comprise well arranged symposiums, one on the combined aspects of reliability and economy in the operation of large electric systems; the other on conductor vibration. The former symposium will represent system operating practise in four different localities: Philadelphia, Detroit, Boston, and Chicago. The latter will present valuable data as a result of both laboratory and field investigations.

Besides these symposiums four other sessions, namely, electrical machinery, electrochemistry-electrometallurgy and research, protective devices, and automatic stations, will afford much of unusual interest in the fields of design, theory, research, and operation. The session devoted to communication should have a broad appeal because of the general interest in the subjects to be presented, and in addition, there will be interesting demonstrations. Still another session on selected topics will offer interesting papers, some of the subjects of which have originated in Cleveland and its environs. One of these relates to the method of wiring buildings as an essential to good illumination. Several others pertain to both synchronous motor and induction motor applications and performance.

For the first time in recent years a session will be devoted entirely to education. Even interests outside of the specific confines of the Institute are being attracted to this session which will start with a paper by Dr. W. E. Wickenden, president of Case School of Applied Science. In order to permit all to participate in this session, the three parallel meetings which occur in the morning will not begin until the conclusion of Doctor Wickenden's address.

### ENTERTAINMENT FEATURES

The opening day will stage the beginning of the annual golf tournament at the beautiful Canterbury Club course, and the beginning of the tennis tournament at the University Club courts. Qualifying rounds for the golf tournament must be played Monday. Those not participating in the tournament may play throughout the week at the Canterbury Club, the Mayfield Country Club, and other private courses.

The president's reception followed by dancing will take place Monday evening at the Hotel Cleveland. Tentative plans have been made for a possible boat trip on Tuesday evening.

An innovation this year will be the substitution of social afternoon and evening for men, women, and children, instead of the usual formal banquet. The entertainment is to be staged on the beautiful grounds of Nela Park, with various field events, dinner and dancing included.

Full details of the generous entertainment program and the several novel features planned for the convention will be given in a program folder being prepared by the Cleveland convention committee, and soon to be mailed by that committee.

### LADIES' ENTERTAINMENT

For the ladies a visit to the Art Museum on University Circle, a drive through the residential sections, and an afternoon tea at Shaker Tavern are planned for Monday. Golf, luncheon, and bridge at the Canterbury Club will be available for them on Tuesday, and among the trips arranged for their entertainment on the following days are visits to a model furnished home built in the Builders' Exchange Building, the Terminal Tower, a radio broadcasting studio and a large modern bakery as well as a drive through the beautiful Metropolitan Park system of the West Side.

### INSPECTION TRIPS

Inspection trips for all interested include the entire route of the recent electrification of the Union Terminal, Avon generating station, d-c. and a-c. substations, the new Ohio Bell Telephone building and exchange facilities, strip mills of the Otis Steel Company representing latest developments in electrification of such mills, and a trip to Akron to visit the many interesting places in that city.

In connection with the previously mentioned entertainment at Nela Park, inspection trips will be conducted during the afternoon. On Friday the entire con-

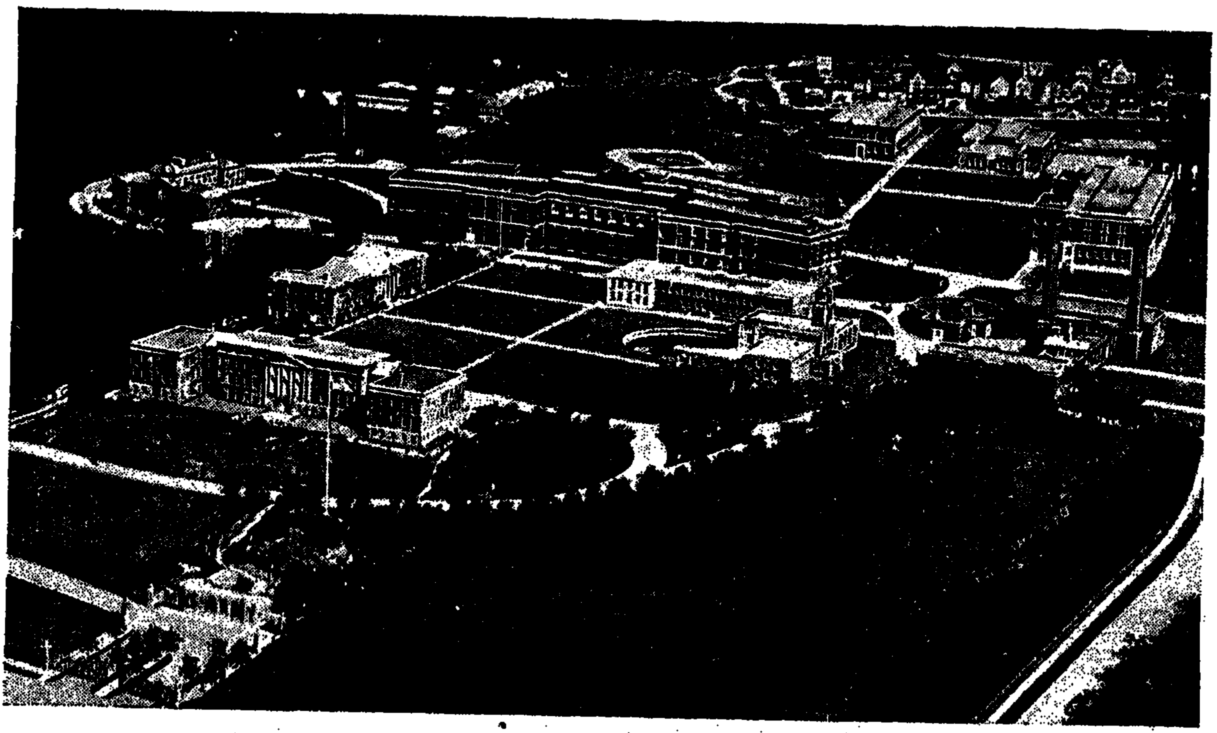
Canterbury Golf Club near Cleveland, Ohio, will be the scene of many hard-fought battles during the rapidly approaching summer convention of the Institute vention will be conducted on a drive through the East Side to observe an abundance of attractive features.

### Registration

There is no registration fee for attendance at the convention. Each member should register in advance by using the post-card to be mailed for that purpose, thus assisting the necessary advance preparation. Registration for the various sports also should be made on the card.

In connection with the entertainment features of the convention there will be a charge of $5 per person, payable upon registration. This fee covers all features except greens fees, and includes the special feature on Thursday which will replace the usual formal banquet.

All hotels noted in the accompanying table are within a five-minute walk of convention headquarters. Reservations for hotel accommodations should be made by writing directly to the hotel preferred.



**Nela Park, in Cleveland, where a novel entertainment feature will be staged this year during the afternoon and evening of Thursday, June 23**

Reduced railroad rates on the certificate plan will be available for those attending the meeting, and summer tourist fares at a lower rate will be in effect from certain western states.

## Program

All technical sessions and the opening of the convention will be held at the Hotel Cleveland. All events are scheduled in *Eastern Standard Time.* Abstracts of papers to be presented at the sessions are scheduled for publication in the June 1932, issue of Electrical Engineering.

| Hotel | Rooms | Single | Double |
|---|---|---|---|
| Cleveland (headquarters) | 1,000 | $3.00–$ 8.00 | $4.50–$10.00 |
| Hollenden | 1,050 | 3.00– 5.00 | 5.00– 9.00 |
| Statler | 1,300 | 3.50– 10.00 | 5.50– 10.00 |
| Winton | 525 | 2.50– 4.00 | 4.00– 5.50 |
| Allerton | 550 | 1.50– 3.00 | 2.50– 4.00 |
| Auditorium | 300 | 2.00– 3.00 | 3.50– 5.00 |
| Olmstead | 300 | 2.00– 3.00 | 4.00– 6.00 |

Hotel rates are for rooms with bath, European plan. Reservations for accommodations should be made by writing directly to the hotel preferred.

### Monday, June 20

**9:00 a.m.—Registration**

**10:00 a.m.—Opening Session**

Annual business meeting of the Institute

Annual report of the board of directors (in abstract)

Report of tellers' committee on election of officers; introduction of and response from president-elect.

Presentation of prizes for papers

Lamme Medal presentation

President's address, by C. E. Skinner

**2:00 p.m.—Conference of Officers, Delegates, and Members**

Inspection trips

**Evening—President's Reception**

### Tuesday, June 21

**9:30 a.m.—Special Session**

*Address on Education—W. E. Wickenden, president, Case School of Applied Science.

**10:15 a.m.—(A) Education**

*The Engineering Subjects, Electrical and Cognate in the Four-Year College Program of Electrical Engineering, A. H. Lovell, University of Michigan

Educational Aspects of Engineering and Management, R. E. Doherty, Yale University

†*Adult Technical Education in Metropolitan Areas, O. W. Eshbach, American Telephone & Telegraph Co.

**10:15 a.m.—(B) Symposium on Combined Aspects of Reliability and Economy in the Operation of Large Electric Systems**

Philadelphia Electric Company's System, J. W. Anderson and Herbert Astrada, Philadelphia Electric Co.

The Detroit Edison Company's System, A. P. Fugill, Detroit Edison Co.

The Edison Electric Illuminating Company of Boston's System, R. E. Dillon, The Edison Electric Illuminating Company of Boston

Chicago District, L. L. Perry and F. V. Smith, Sargent and Lundy, Inc.

**10:15 a.m.—(C) Electrochemistry—Electrometallurgy and Research**

*Electrical Equipment for Precipitation Service, H. Speight, Westinghouse Electric & Mfg. Co.

*Oxide Coatings on Aluminum, J. D. Edwards, Martin Tosterud and H. K. Work, Aluminum Company of America

*Calculation of Inductance and Current Distribution in Low Voltage Connections to Electric Furnaces, C. C. Levy, Westinghouse Electric & Mfg. Co.

*New Applications of Non-linear Circuits to Relay and Control Problems, C. G. Suits, General Electric Co.

**2:00 p.m.—Conference of Officers, Delegates, and Members (cont'd)**

Inspection Trips

### Wednesday, June 22

**9:30 a.m.—(D) Electrical Machinery**

The Coordination of Transformer Insulation With Line Insulation, V. M. Montsinger, General Electric Co., and W. M. Dann, Westinghouse Electric & Mfg. Co.

*Coordination of Distribution Transformers, E. D. Treanor and W. H. Cooney, General Electric Co.

*Load Ratio Control Circuits, L. F. Blume, General Electric Co.

Influence of Brush Contact Drop on Commutation, L. R. Ludwig and R. M. Baker, Westinghouse Electric & Mfg. Co.

*Single-Phase Short-Circuit Torques of Synchronous Machines, C. A. Nickle and M. L. Henderson, General Electric Co., and C. A. Pierce, Worcester Polytechnic Institute

†Transient Analysis of A-C. Machinery II, Extension to Salient-Pole Machines, Yu H. Ku, University of Chekiang

**9:30 a.m.—(E) Communication**

*Wire Communication Aids to Air Transportation, H. H. Nance, American Telephone & Telegraph Co.

*Characteristics of Electromagnetic Radiation From Aircraft in Flight, J. C. Coe and T. C. Rives, Signal Corps, War Department

*Vertical Sound Records, H. A. Frederick and H. C. Harrison, Bell Telephone Laboratories, Inc.

**2:00 p.m.—Trip to Akron**

## Notice of Annual Meeting

The annual meeting of the American Institute of Electrical Engineers will be held in the Hotel Cleveland, Cleveland, Ohio, at 10 a.m. on Monday, June 20, 1932. This will constitute one session of the annual summer convention, which is to be held this year in Cleveland, June 20–24.

At this meeting the annual report of the board of directors and the report of the committee of tellers concerning the ballots cast for the recent election of officers will be presented.

Such other business, if any, as properly may come before an annual business meeting may be considered.

(Signed) H. H. Henline
*Assistant National Secretary*

**Thursday, June 23**

**9:30 a.m.—(F) Selected Subjects and Technical Committee Reports**

*Adequate Wiring of Buildings, An Essential for Good Illumination, G. H. Stickney and Walter Sturrock, General Electric Co.

*Induction Motor Versatility—The Nature of Its Applications, E. W. Henderson, The Reliance Electric and Engineering Co.

Dynamic Braking of Synchronous Machines, E. E. Kilbourne and I. A. Terry, General Electric Co.

**9:30 a.m.—(G) Protective Devices**

Application of High Speed Relays, G. W. Gerell, Union Electric Light and Power Co.

A High Speed Reactance Relay, A. R. van C. Warrington, General Electric Co.

†Relay Operation From Bushing Potential Devices, P. O. Langguth and V. B. Jones, Westinghouse Electric & Mfg. Co.

†Operation of Relays From Carrier-Current Coupling Capacitors and Capacitance Transformer Bushings, J. E. Clem and R. M. Cordray, General Electric Co.

The Boric Acid Fuse, A. P. Strom and H. L. Rawlins, Westinghouse Electric & Mfg. Co.

**Afternoon and Evening—Entertainment at Nela Park**

**Friday, June 24**

**9:30 a.m.—(H) Automatic Stations**

*Torque Balance Telemetering, A. J. Johnston, General Electric Co.

*Developments in Two-Wire Supervisory Systems, J. H. Oliver, General Electric Co.

*Operating Experience With Supervisory Control on the Reading-Philadelphia Suburban Electrification, J. E. Pastoret, Reading Co.

*The Application and Performance of Automatic Equipment at Stations and Substations on The American Gas and Electric Company's System, Philip Sporn, Basil Lanphier and H. E. Turner, American Gas and Electric Co.

**9:30 a.m.—(I) Symposium on Conductor Vibration**

Stress-Strain Studies of Transmission Line Conductors, G. W. Stickley, Aluminum Research Laboratories

Vibration and Fatigue in Electrical Conductors, A. E. Davison, J. A. Inglis, and V. M. Martinoff, Hydro-Electric Power Commission of Ontario

*Vibration of Overhead Transmission Lines, R. A. Monroe and R. L. Templin, Aluminum Company of America

*Transmission Line Vibration Due to Sleet, J. P. Den Hartog, Westinghouse Electric & Mfg. Co.

---

* These papers are under consideration for presentation at the summer convention, but up to date of going to press have not been officially placed upon the program.

† These papers will not be published in the Transactions or in advance form by the Institute but copies may be made available by the respective authors.

### Rules on Presenting and Discussing Papers

At the technical sessions papers will be presented in abstract, ten minutes being allowed for each paper unless otherwise arranged, or the presiding officer meets with the authors preceding the session to arrange the order of presentation and allotment of time for papers and discussion.

Any member is free to discuss any paper when the meeting is thrown open for general discussion. Usually five minutes are allowed each discussor. When a member signifies a desire to discuss papers on other subjects or groups, he shall be permitted a five-minute period for each subject or group.

It is preferable that a member who wishes to discuss a paper give his name beforehand to the presiding officer of the session at which the paper is to be presented. Copies of discussion prepared in advance should be left with the presiding officer. Each discussor is to step to the front of the room and announce, so that all may hear, his name and professional affiliations. Discussions at the technical sessions are not reported. To be considered for publication, discussions should be written and mailed to the A.I.E.E., Editorial Department, 33 West 39th Street, New York, N. Y., on or before July 8, 1932.

# Summarized Review of Some Milwaukee Meeting Discussions

PRINCIPAL discussions of Milwaukee District meeting papers are summarized herewith. The papers to which these discussions refer were abstracted in Electrical Engineering for March 1932, p. 188–92. Additional articles based upon these papers are being presented in subsequent issues.

Only discussion submitted in writing in accordance with governing A.I.E.E. rules is summarized. Complete discussion together with all approved papers will be published in the Transactions.

### Toll Switching Plan for Wisconsin

In connection with this subject E. W. Neubauer (Chicago, Ill.) discussed several features in effect under the toll switching plan in Illinois. He explained that one of the important results of the application of the toll switching plan is the improved toll service to small communities located somewhat away from the larger cities.

Glen Ireland (New York, N. Y.) discussed the general toll switching plan as a whole which covers the entire United States and eastern Canada. Only a few per cent of the circuit groups required to complete the routing arrangements of the general toll switching plan within the Bell System remain to be placed, and these represent less than 1 per cent of the circuit miles now in service. He referred also to the excellent progress that has been made in providing terminal repeater-switching pad arrangements at the more important switching centers throughout the country.

R. C. Siegel (Milwaukee, Wis.) also discussed this subject and cited advantages of the toll switching plan. He explained that limiting switching to fewer toll centers results in the concentration of larger numbers of toll circuits on a smaller number of main routes and the concentration of equipment in fewer central offices. Plans in Wisconsin within the next few years and ultimate planning also were discussed briefly.

### Police Teletypewriter Communication

E. W. Neubauer (Chicago, Ill.) discussed this subject and referred to the various types of systems in use. The particular telegraph line system used for each link depends largely upon the length of the circuit and the type of telephone wires in use between the terminals. Maintenance methods for these police systems were explained and the importance of continuity of service at all times emphasized.

J. O. Carr (Park Ridge, Ill.) cited the many advantages from the use of this system by comparison with the older method of broadcasting and rebroadcasting telephone messages which permitted human error to enter into the problem and required a longer period of time on the receiving end of the system.

### Weather Resistant Insulation for Line Wires

C. D. Brown (Milwaukee, Wis.) stated that his experience with the use of tree wire indicated that its outer covering had in many cases the same deficiencies with respect to impregnating compound as was brought out in the paper regarding weatherproof insulation. He inquired if investigation had been made of the properties of the weather resistant covering for tree wire, and if so, what were the results?

James H. Foote (Jackson, Mich.) also discussed this subject and it is his belief that seven years' life of weatherproofing on overhead wire would seem to be abnormally short. He cited a case where triple braid weatherproof had been in service eighteen years without showing any appreciable amount of raggedness or deterioration easily visible from the ground.

### Waukegan Station

A. H. Lovell (Ann Arbor, Mich.) believed that to one not familiar with Chicago and its western surroundings, the choice of only 25,000-kw. units in 1923 and 65,000-kw. units in 1930 was puzzling. The authors were asked to discuss this reference to the size of the load in Chicago at those times.

W. S. Monroe (Chicago, Ill.) brought out that the history of this power station represented in a large measure the development of the power station industry in the Chicago district so far as steam pressure and steam temperature are concerned and the change of boiler furnaces from chain grate stoker to pulverized coal. He also explained that the last three units installed, numbers 3, 4, and 5, were each the largest single shaft units available at the time they were ordered.

### 115,000-Kw. Turbo-Alternator

S. H. Mortensen (West Allis, Wis.) discussed several of the design features of this generator which brought about a reduction of vibrations, stray fields, heating, etc. The advantages of substituting non-magnetic for magnetic coil supporting rings on the leakage fields and stray losses of a 2,500-kva., 3,600-r.p.m. generator were shown with curves.

One of the many points of interest discussed by C. J. Fechheimer (Milwaukee, Wis.) was the possible influence of the foundation of this generator, on its critical speed. He believes that in all probability the running speed is above the first critical speed and that it is important to remember that the influence of the foundation might lower the critical speed, and then there would be danger of encountering a higher critical speed near the running speed.

Philip Sporn (New York, N. Y.) inquired whether the use of hydrogen was given consideration in connection with the design. He believes that in addition to the improved performance of an 18-kv. winding possibly hydrogen would have raised the efficiency to a figure as high as 99 per cent and increased the rating by well over 1,000 kw. which would have justified considerable extra expenditure.

### Mercury Rectifiers for A-C. Railways

In connection with the use of rectifiers instead of commutators L. R. Ludwig (East Pittsburgh, Pa.) considers the rectifier as a unidirectional switch whereas the commutator and brush he pointed out would pass current in either direction. Also the rectifier for practical reasons must have a comparatively small number of anodes or segments, whereas the commutator usually has many. Therefore, the utilization of the windings on the motor it is believed would not be nearly so good as if a commutator were used.

R. E. Hellmund (East Pittsburgh, Pa.) discussed the scheme proposed in this paper and pointed out that while considerable progress has been made in the development of rectifiers and similar electronic devices, however, perhaps even greater advances have been made in the design of single-phase motors. It is believed that their relative position today is about the same as in the early days and that present rectifier arrangements cannot compete economically with single phase commutator motors.

E. F. W. Alexanderson (Schenectady, N. Y.) is of the opinion that this development will lead to a practical solution because progress of the vacuum tube technique is rapidly leading to new and superior forms which in their turn make possible improved methods of correlating the power system, the vacuum tube, and the motor.

R. G. McCurdy (New York, N. Y.) discussed the probable inductive effects that would result from the use of the controlled grid mercury arc rectifier which may be expected to complicate the problems of coordination between single-phase a-c. railways and telephone circuits.

H. M. Trueblood (New York, N. Y.) in connection with this subject analyzed several factors and general observations based upon a comparison of the use of single-phase 25-cycle and 60-cycle energy upon the contact wire of an electrified railway using the running rails for return.

### Mercury Rectifiers Versus Rotary Converters

D. C. West (East Pittsburgh, Pa.) emphasized the statements in the paper regarding the importance of service reliability. He also pointed out that within the past few years, the results of many years of development effort have brought the rectifier substation to the point where its existence is thoroughly justified throughout the field of d-c. railway power supply.

W. E. Gutzwiller (Milwaukee, Wis.) presented data which showed that the operating costs and service failures of the rectifiers mentioned in this paper were rather high in comparison with similar, but more modern, stations.

### A 60-Cycle Transmission System

C. L. Fortescue (East Pittsburgh, Pa.) discussed the protective features of the line of the Milwaukee Electric Railway and Light Company described in the paper. He believes the spacing and height of the ground wires above the line wires should produce good shielding effect. Also as a large part of the line follows the railroad right-of-way, good grounding should be obtained and with the liberal tower clearances, a good record against lightning should be obtained with this line.

### Insulator Sparkover

C. L. Fortescue (East Pittsburgh, Pa.) also discussed this subject and is of the belief that these papers cover research producing data which has been greatly needed by the industry; namely, the effect of humidity upon the 60-cycle flashover of different types of insulating structures.

In regard to this subject, A. O. Austin (Barberton, Ohio) pointed out that where humidity is high it is very important in making the tests that insulators be at room temperature, as otherwise large discrepancies may arise.

Philip Sporn (New York, N. Y.) referred to previous discrepancies in 60-cycle flashover of insulators as given by different manufacturers. Subsequent work of the lightning and insulator subcommittee showed that this was due largely to the different humidity conditions under which tests were made. Mr. Sporn believes that this paper definitely confirms the point and shows how consistently the results appear when plotted against relative humidity.

### A Limiting Gap for Station Apparatus

C. L. Fortescue (East Pittsburgh, Pa.) complimented the author on the good work which he had done, especially in pointing out the necessity of coordinating insulation for positive as well as negative surges.

W. L. Lloyd, Jr. (Pittsfield, Mass.) does not agree with conclusions 1 and 3 giving the requirements which an ideal gap should have and its use in the station; he believes also that a great many tests would be necessary before one could be certain that conclusion 2 was justified. It was felt that the value of the paper might possibly have been enhanced if the measured test points of the curves had been given.

J. T. Lusignan (Mansfield, Ohio) analyzed the two principles involved in connection with the control type of limiting gap which provides for a wide variation of electrostatic field in order to secure practically any sparkover characteristic desired. Reference was made to several simple gap arrangements to illustrate the effect of uniformity of voltage gradient across the gap upon time lag of the gap; also to illustrate the effect of an unsymmetrical electrostatic field upon the polarity at which a gap will have a lower breakdown voltage.

J. J. Torok (East Pittsburgh, Pa.) emphasized the importance of the following points in the paper: first, the differences between the positive and negative flashover characteristics of various gaps and their importance in coordination; second, the relations of flashover between waves of various durations and the volt-time curve obtained by a flat-topped wave.

J. F. H. Douglas (Milwaukee, Wis.) discussed this paper and he believes that the different behavior of points and spherical electrodes with positive and negative electrification were clearly shown to be in accord with the electrostatic field theory, and were verified amply by experimental tests. He thought that future work might well be directed toward some of the details which are not yet fully explained.

### Diameter and Spacing of Insulators

C. L. Fortescue (East Pittsburgh, Pa.) in his discussion of this subject emphasized that there was nothing untried in the type of insulators proposed. He explained that insulators of this diameter and larger have been in use on the Pacific Coast, giving good service; and they are just as sturdy as the standard 10-in. suspension insulator.

N. B. Obbard (of the American Bridge Company) discussed this subject in its relation to tower design. He believes this paper is one of the first in which the economic relation of the insulator string to the cost of the tower has been taken into consideration, and that both insulators and tower design should be considered at the same time and not as separate problems.

Another discussion of this subject by A. O. Austin (Barberton, Ohio) also pointed out that with the more efficient insulator it is possible to reduce the clearances and the height of tower, so that the probable number of hits to the line will be less. Also with less clearance the line reactance is reduced and capacitance is increased, so that more power may be transmitted and the stability bettered.

In connection with the part of this paper which deals with the question of diameter and spacing, Philip Sporn (New York, N. Y.) believes that the value of this information would have been greatly enhanced had the tests been confined to practical designs and to spacings and diameters within the commercial range.

W. L. Lloyd, Jr. (Pittsfield, Mass.) discussed the wave shapes used for the tests in this paper. With regard to the wave shape shown in Fig. 1-B, he believes that sparkover of a test piece would take place at or near the crest of such a wave or not at all; consequently, high sparkover values and impulse ratios are obtained. The laboratory wave shown in Fig. 2, he believes, should give values lower than those measured in the field.

FLASHOVER VALUES OF INSULATORS

A. O. Austin (Barberton, Ohio) in discussing the subject of normal frequency flashover values of insulators as affected by humidity and size, explained that there are so many factors involved which affect the flashover of an insulator that general laws cannot be established which apply to all types of insulators. The correction for humidity therefore must be determined largely by test on the particular insulator or one approximating its general characteristics.

Philip Sporn (New York, N. Y.) believes that this paper checks closely with the information furnished by Mr. Lloyd's paper. He believes that plotting data on the behavior of insulators under different humidity conditions against abscissas of vapor pressure is certainly the most scientific manner of presenting the data.

Another discussion of this subject by J. C. Rah (Chicago, Ill.) brought out that the results obtained on insulators from experiences of many observers indicated that air spaces are responsible for reduced flashover rather than wet surfaces, and therefore the wet flashovers are entirely a function of design.

# Summarized Review of Some Winter Convention Discussions—Continued

PRINCIPAL discussions of the majority of winter convention papers were summarized in ELECTRICAL ENGINEERING for April 1932, p. 272–9. The remainder is presented herewith. The papers to which these discussions refer were abstracted in ELECTRICAL ENGINEERING for January 1932, p. 39–49 and February 1932, p. 130–2, excepting only the papers given more complete treatment in these same issues; additional articles based upon these papers are being presented in subsequent issues.

Only discussion submitted in writing in accordance with governing A.I.E.E. rules is summarized. Complete discussion together with all approved papers will be published in the TRANSACTIONS.

## Electrical Machinery

PARALLELED ROTOR AND STATOR

In connection with this subject H. B. Hall (New Haven, Conn.) pointed out that the same performance as the authors obtain may be secured from a normally connected induction motor by running it on $\sqrt{2}$ times normal voltage. This, he explained, could be done to any induction motor even if its rotor and stator were wound for different voltages or if it had a squirrel cage rotor.

R. E. Hellmund (East Pittsburgh, Pa.) considered the probability of this special arrangement being used for general purpose work which he believes does not seem likely because usually the same results can be obtained with the ordinary induction motor. Nevertheless he thinks it might be useful in special cases, as, for instance, where speed-torque characteristics as shown in Fig. 12-C of the paper are desirable; therefore the publication of the results obtained should be considered a welcome
on to the art.

ortescue (East Pittsburgh, Pa.)
sed this subject and analyzed
y the method of symmetrical
It was shown that the output
e copper loss was increased
41.4 per cent. To offset this the inductance was doubled but the rotor iron loss and the stator iron loss would have approximately the same magnitude, so that the iron loss for the same applied voltage would be approximately double that in the regular induction motor.

DAMPER WINDINGS FOR MOTORS

M. R. Lory (East Pittsburgh, Pa.) said that the problem of the designer was to meet the torque requirements of the load and still keep the current drawn from the line to a minimum. He believes the paper gave a comprehensive summary of the various means by which the designer can accomplish this result. As a matter of interest in connection with two double-deck arrangements in the paper the discusser explained that he had calculated these two examples with two bars in parallel but in separate slots, making the permeance of the slot above each the same as the permeance which it has in the arrangement given in Fig. 7 of the paper. The values of the constants for the two bars were given.

Another discussion of this subject by R. E. Hellmund (East Pittsburgh, Pa.) answered the question as to why the various exciter and phase-advancer schemes for induction motors have not been commercially exploited in this country. He expressed belief that this paper is further evidence of the excellent progress which continuously has been made by American designers of synchronous motors in the development of motors suitable for the many commercial applications.

POWER TRANSFORMER DESIGN

R. E. Hellmund (East Pittsburgh, Pa.) in his discussion of this subject drew comparisons between the methods of surge testing now arrived at in this country, and those which were in effect with most manufacturing concerns in Europe during the summer of 1925. The practise now arrived at in this country is, as a result of the more deliberate method of developing it, in marked contrast to the European methods, and in regard to transformers, it is much more rigorous.

F. W. Peek (Pittsfield, Mass.) in his discussion of this subject attributed the paper by Palueff and Hagenguth as one of a pioneer series which has placed the subject of transients in transformer windings upon a scientific and engineering basis. In the light of new knowledge resulting from this series of papers the discusser again recommended that the committee on electrical machinery set up methods, waves, etc., for making a lightning test on transformers if such a test should seem desirable.

Another discussion by C. L. Fortescue (East Pittsburgh, Pa.) reviewed the historical background leading up to the present development of surge-proof insulation and winding in transformers. The other phase of Mr. Fortescue's interesting discussion predicted in the light of present knowledge the magnitude of the surges to which a transformer might be exposed in certain situations. His remarks were confined to transformers designed for 110-kv. operation, and the analysis considered only direct strokes on both wood pole and steel tower line construction. The latter was classified into three conditions, namely, unprotected lines, imperfectly protected lines and well protected lines.

F. W. Gay (Newark, N. J.) discussed this subject and proposed to provide a transformer with a resistance path in parallel with a winding to be protected, and electrostatically couple the resistance path with the winding and with the transformer terminals, so that relatively very great currents will pass to charge the winding for high frequency surges but relatively insignificant current will pass through the resistance at normal frequency. A surge winding of relatively few turns with the high frequency winding coupled to the transformer terminals by condensers also could be wound in juxtaposition with the many-turn low-frequency high-voltage winding. Thus an advantageous shunt path of very low surge impedance would be provided through the condenser and high-frequency few-turn surge winding.

A. B. Hendricks, Jr. (Pittsfield, Mass.) did not believe that some of the fundamental improvements claimed in the surge-proof construction were new. He submitted drawing of several test transformers, one of which he designed, built and put in service in 1906 to exemplify the fundamental principles involved. He described the winding which was of the concentric form with circular coils with insulation varied more or less in proportion with the voltages. By the use of interleaved cylinders, flanged rings and formed insulating casing, it presented an absolute barrier between the high voltage winding, low voltage winding, and core.

## Electrochemistry and Electrometallurgy

LOSSES IN ELECTROLYTIC CONDENSERS

J. Slepian (East Pittsburgh, Pa.) discussed this paper and he told of work which he carried on about twelve years ago in connection with the high power factor usually obtained. He found that the addition of a fractional per cent by weight of a soluble fluoride had an extremely beneficial effect upon the power factor and reduced the losses so that cells were made with power factors under 2 per cent. However, these cells with superposed d-c. excitation would not stay efficient and in the course of a year the power factor would become 5 or 6 per cent, and it would continue to rise slowly for years afterward. Investigation showed that there was a change in electrolyte which was assumed to have been the formation of colloidal aluminum hydroxide and the inquiry was made as to why such a substance should effect the losses in the cell.

H. H. Race (Schenectady, N. Y.) also discussed this paper with reference to an explanation of the power-factor frequency characteristics of electrolytic capacitors. He believes that if the coefficients of capacitance and resistance in Fig. 25 of the paper could be assumed to be independent of frequency then the complicated combination of series and parallel arrangements of resistance and capacitance could be reduced to an equivalent circuit. On the other hand he does not believe that the coefficients in Fig. 26, which may be only a special case of a more general form, could be assumed to be independent of frequency since the ionic concentration at a given point in the oxide film would change with time.

### ELECTRICAL PRECIPITATION

J. J. Torok (East Pittsburgh, Pa.) discussed this subject and believes that the authors presented very effectively the results of their experiments. He reviewed a treatise on this subject by Ladenburg which attacked the problem from a different point of view than that taken by the authors of this paper. From this analysis it was found that in precipitators the larger particles would be removed first and as time progressed the smaller particles also would be taken out.

Another discussion by J. C. Hale (Bound Brook, N. J.) took exception to a number of conclusions reached in the paper as well as some of the authors' equations. One of the points questioned by the discusser concerned the mathematical analysis leading to eq. 15 in the paper which shows that identical efficiencies will obtain whether precipitator units be connected in series or in parallel or in series parallel with respect to gas flow, provided the gas is properly divided in the case of unsymmetrical arrangements. For example, in a problem requiring a very low friction loss, eq. 15 points to the use of a large number of units in parallel. The discusser explained that it could be shown mathematically that the combined efficiency of parallel units decreases rapidly as the gas distribution becomes unequal. Equal distribution of gas through too many parallel units was believed to be most difficult and the selection of a proper number of units to be parallel was therefore not a matter of efficiency calculated on the basis of any formula, but a matter of experience with regard to distribution. The discusser felt that in justice to the scientists and engineers, who have devoted much work to the art that the part of the authors' conclusion which referred to work done heretofore should be sincerely questioned.

## Transportation

### THREE-POWER LOCOMOTIVES

W. S. H. Hamilton (New York, N. Y.) discussed the requirements and performance of these locomotives used by the New York Central around New York City. He explained that the size of the internal power plant (300 engine hp.) was based on requirements in the 60th Street yard where there was heavy switching and float work.

With regard to the ability of the internal power plant to meet emergency conditions it was explained that these locomotives successfully handled 2,000-ton trains in regular road service over a distance of 8 miles for a period of 11 months. It was pointed out that for the year 1931 the whole fleet of 36 locomotives was in service with crews on 61 per cent of the time and were available for service 85.5 per cent of the time. This performance with new locomotives and new crews was considered very creditable.

Another discussion of this paper by D. P. Orcutt (New York, N. Y.) considered the expected battery life on the three-power locomotive as compared with the straight storage battery locomotive for switching service. Data on the operation of the first three-power locomotive on the New York Central showed that in switching service about 85 per cent of the energy used by the traction motors flowed directly from the generator to the motors and 15 per cent from battery to the motors. This permits the use of a much smaller battery with a three-power unit, thus greatly reducing battery maintenance cost from that with a straight battery locomotive in switching service.

F. H. Craton (Erie, Pa.) discussed this subject and briefly described requirements in connection with the New York Central's west side improvement which were largely responsible for the development of the three-power locomotive. In comparing the three-power locomotive to the two-power design it was brought out that the engine-generator-battery type was best fitted for operation in service where peak demands are high and the load factor low. The three-power type also possesses the additional advantage of being able to operate on battery power into buildings or restricted areas.

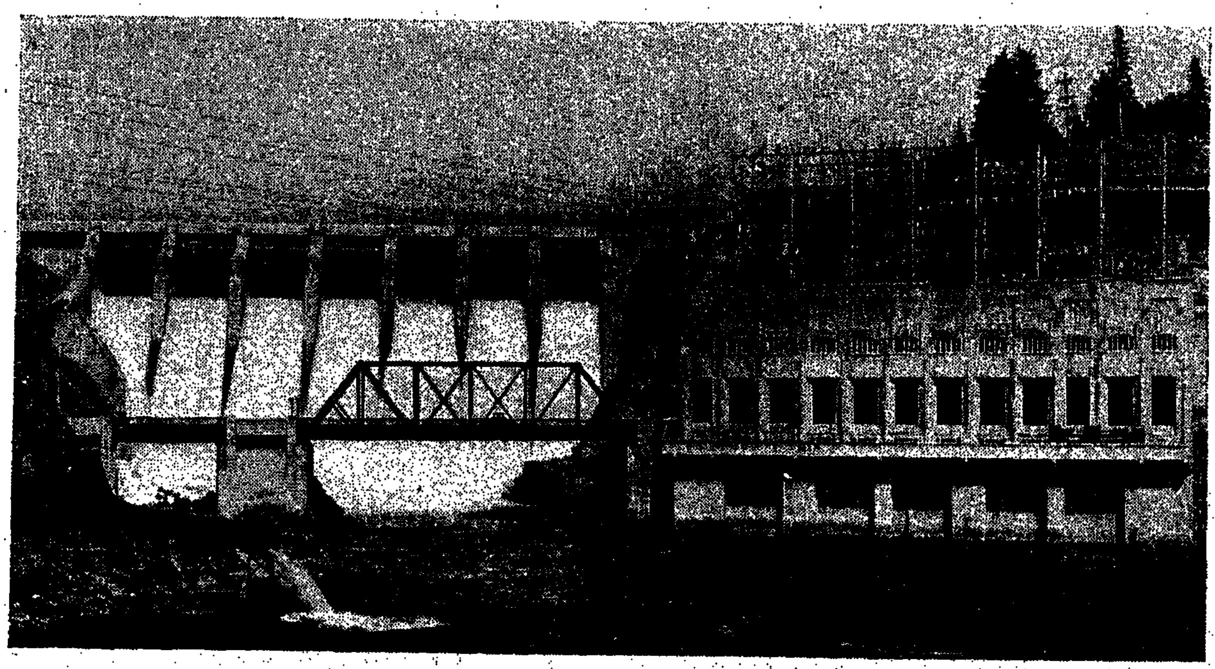
F. H. Brehob (Erie, Pa.) also discussed the subject and described a number of the difficult problems in mechanical design that had to be solved to meet the severe service requirements. The locomotive as developed represents the heaviest four-axle swivel truck locomotive in service today and it utilizes the heaviest axle loading using single-geared axle-hung motors. The weight in working order was limited to 257,000 lb. by utilizing material to best advantage.

Herman Lemp (New York, N. Y.) also discussed the paper and considered the advantages of another engine equipment of 300 hp. to take the place of the battery. He explained that this would not cost or weigh more than the battery which was good only for four years, while the engine equipment if properly maintained would be available at least for ten years.

### TEMPERATURE RISE OF RAILWAY MOTORS

John Basta (East Pittsburgh, Pa.) discussed this subject and explained that the actual heat runs used for verifying the calculated curves, however, did not give more than two, and in some cases even only one point. It was suggested that the author undertake another series of tests in which complete curves would be obtained. Instead of measuring the resistances of armature windings, as was done in the tests

## On Program for the Pacific Coast Convention



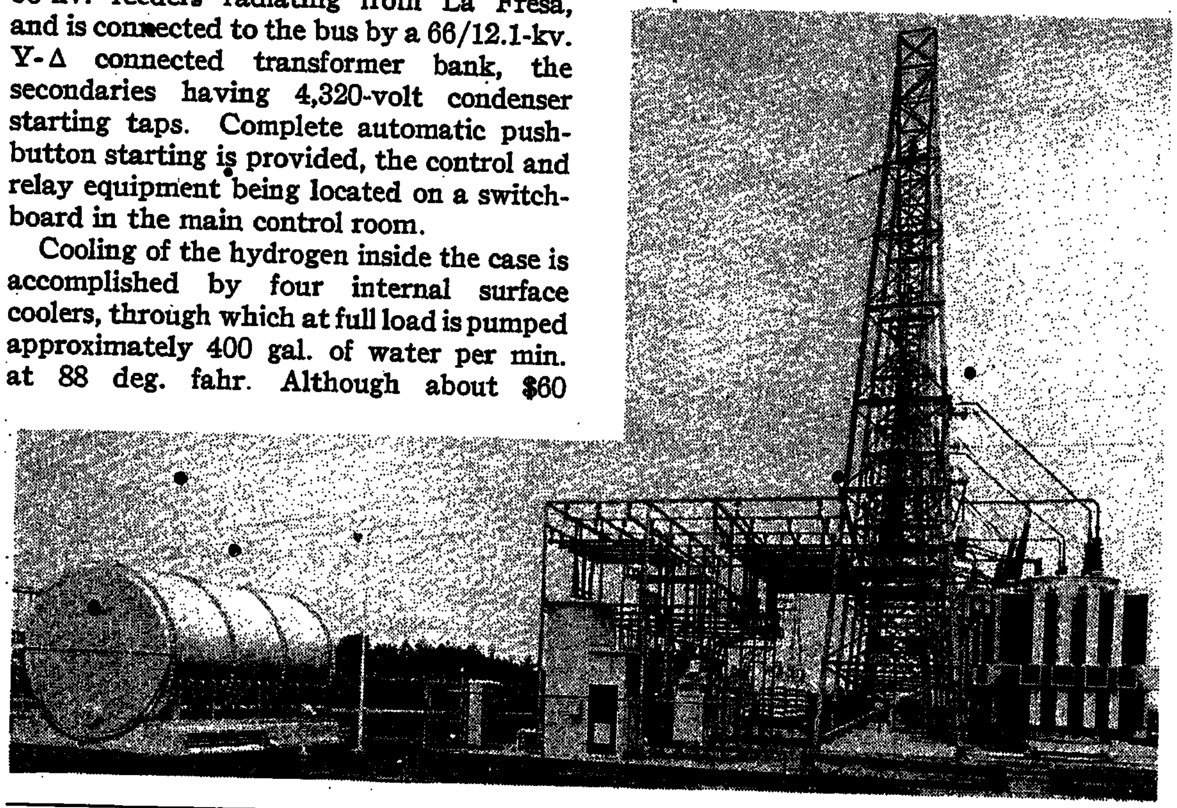
THE RUSKIN hydroelectric plant of the British Columbia Electric Railway Company may be visited by those attending the A.I.E.E. Pacific Coast convention which is planned to be held Aug. 30–Sept. 2, 1932, at Vancouver, B. C. One 47,000-hp. unit is now installed in the Ruskin plant, the ultimate capacity of which will be 188,000 hp. in four units.

# 50,000-Kva. Hydrogen-Cooled Condenser at La Fresa

Reduction of noise, reduced operating temperatures, decreased windage losses, increased efficiency, saving in installation cost, and elimination of the requirement for special fire-fighting equipment are among the benefits secured with this outdoor hydrogen-cooled synchronous condenser. Located at the La Fresa substation of the Southern California Edison Company, Ltd., this condenser is rated 50,000 kva., and is the largest hydrogen-cooled unit ever constructed. It is used for voltage regulation and power factor correction of the 66-kv. feeders radiating from La Fresa, and is connected to the bus by a 66/12.1-kv. $Y$-$\Delta$ connected transformer bank, the secondaries having 4,320-volt condenser starting taps. Complete automatic push-button starting is provided, the control and relay equipment being located on a switchboard in the main control room.

Cooling of the hydrogen inside the case is accomplished by four internal surface coolers, through which at full load is pumped approximately 400 gal. of water per min. at 88 deg. fahr. Although about $60 worth of hydrogen is needed to fill the machine, the cost of make-up hydrogen has averaged less than 10 cents per day during the first 4 months of operation.

The condenser and starting and running circuit breakers were manufactured by the General Electric Company, and the transformers by the Westinghouse Electric and Manufacturing Company. Four 1,250,000-cir. mil. 16-kv. Kerite insulated cables in parallel are used for each of the three main condenser leads.



presented, it was suggested that temperature detectors be placed into the winding which would be connected through slip-rings to meters, so that the distribution of temperatures along the winding could be ascertained at the same time.

C. J. Fechheimer (East Pittsburgh, Pa.) discussed several of the author's assumptions made in the paper. It was believed essential to make assumptions such as the author had done although these might not be the ones to adopt for some other class of apparatus. It was explained that the author's results were all based upon the average copper temperature as measured by resistance. For machines having long cores, the copper at the middle is usually at considerably higher temperature than the average, and consequently assumption *B* in the paper would introduce too large an error.

### Sectionalizing of Rectifier

A. W. Hull (Schenectady, N. Y.) discussed the part of the paper which related to the fundamental limitation of rectifiers, namely, the prophecy that "the major disadvantages which go with size appear to be fundamental and permanent. Larger units will always be less efficient and probably less reliable." He explained why theory and present experience did not seem to him to justify this conclusion. He believed that if large rectifiers were at present less efficient than small ones, it was a mere chance which was due to the relative state of development, and not a fundamental limitation of large rectifiers.

R. E. Hellmund (East Pittsburgh, Pa.) discussed the reliability and availability of the sectionalized designs versus large units. He cited as an analogy, discussion which took place in the early days of a-c. main-line electrification regarding the relative merits of locomotives having one or two large motors and those having many small motors. Practical experience showed that the reliability and availability with the large motors was low because such unavoidable accidents as the breaking of a single carbon might damage the commutator and keep the locomotive out of service. On the other hand a similar occurrence in the locomotives having many small motors, that is, sectionalized power, permitted quick replacement and much greater availability of the locomotives.

Another discussion by C. A. Butcher (New York, N. Y.) explained that heretofore he had not been an enthusiast for mercury arc power rectifiers but the advantages of the new development described in the paper and the indications, from extensive research laboratory work and testing, of a higher order of reliability have lead him for the first time to be enthusiastic about a rectifier.

W. E. Gutzwiller (Milwaukee, Wis.) also discussed this paper and it is his belief that the claims made for this rectifier were somewhat overemphasized. He pointed out that experience has shown that small sectional types have usually been later supplanted by large single-tank types for reason of simplicity and reliability except in very special cases where other considerations were dominant. This, he believes, is particularly true on fluctuating loads, such as heavy traction service where a real gain in reliability is of more importance than a slight gain in efficiency.

## Symposium on Time and Time Services

L. S. Harrison (New York, N. Y.) described a master clock system which hourly supervises the uniform agreement of electric secondary units. In this system the master clock, with a high-grade 60-beat pendulum regulator which is capable of rating within 2 to 3 sec. per month, transmits over an individual three-wire system its own accuracy to the secondary time pieces, both as to rate of advance and as to a point origin of time by means of a periodic time check. The system was introduced in 1924 and it has had wide application throughout the United States and Canada.

The inventions of Mathias Hipp, who was a pioneer in the art, were interestingly brought out by Herman Lemp (New York, N. Y.) in his discussion of this subject. It was explained that Mathias Hipp's electric clocks are known all over Europe. They have been in continuous service in the principal cities of Switzerland since about 1868 and furnish accurate time to a critical public, makers of Swiss watches and chronometers. This inventor was also the first to construct an astronomical pendulum of steel with mercury compensation.

J. D. Crawford (Cambridge A, Mass.) in his discussion of this subject referred to the series of experiments undertaken by the late Dr. A. A. Michelson. These experiments involved the determination of the time it took light to travel ten times between two sets of mirrors placed at the ends of an evacuated tube about a mile long. In making these measurements a crystal clock was used as the reference standard.

### Telegraph Time Service

In connection with this subject W. A. Dudley (New York, N. Y.) explained that usually one or more synchronized clocks in each office of the telegraph companies are provided with cam-operated contacts which, through suitable relays, are used for the control of timing and dating stamps. Thus these clocks, which are part of a synchronized time service described in the paper, provide an accurate means for controlling and checking the speed of service.

J. C. Wilcox (New York, N. Y.) also discussed this paper and referred to the movements, construction, and application of the subscribers' clocks. He pointed out that these clocks are independent operating units with the ability to operate continuously and accurately regardless of outside line interruptions. He explained that these self-winding clocks were found on every railroad and subway system in New York with the largest installation in the Grand Central Terminal where over 1,000 units are operated.

Another discussion by R. C. Thayer (St. Paul, Minn.) brought out the value of the noon beat signals as sent out by the two telegraph companies to the railroads of this country. These signals are redistributed throughout the railroad companies networks of communication circuits so that each of the railroad stations and train dispatchers receive the correct time daily.

SYNCHRONOUS ELECTRIC TIME SERVICE

This subject was discussed by Philip Sporn (New York, N. Y.) who believed that a reading of the paper was likely to give the wrong impression—that the question of frequency control by operators of large power systems was a simple matter, involving little more than the use of a master clock. Some of the difficulties involved in frequency regulation on an interconnected system were explained by the discusser and illustrated by load charts of a tie line which showed the wide fluctuations caused by close frequency regulation.

R. J. Wensley (Newark, N. J.) also discussed this subject and brought out that the first interest displayed by the central station industry in synchronous timekeeping was in the use of such methods for the integration of demand against definite time intervals. He also pointed out that at present the usual power system is not regulated with sufficient accuracy to permit the use of synchronous timing of extremely short intervals.

**The Bonbright Survey** of electric light and power companies of the United States, eighth edition, revised September 1931, recently was issued by the McGraw-Hill Publishing Company, Inc., of New York. According to the foreword in this volume the first edition of the survey was compiled in 1923 by Bonbright and Company, Inc., investment bankers closely identified with the electric power and light industry. Since January 1926, the publication has been compiled and issued by the McGraw-Hill company. In the present edition, corporate relationships and territories served are given as received until November 1931, in reports from the power companies concerned, while financial statistics are given, so far as was possible, as of June 30, 1931. The list of holding corporations and subsidiary companies has been revised; financial data have been augmented to include more of the municipal and smaller privately owned properties; listings of incorporated cities and towns having a population of not less than 2,500 have been augmented to include results of the 1930 census. The published price is $10 per copy.

**Successor to C. L. Edgar Appointed.**—Announcement has been made of the election of W. C. Baylies as president of the Edison Electric Illuminating Company of Boston, Mass., at a special meeting of its directors. He succeeds C. L. Edgar (A'96, F'12) who died suddenly April 14, 1932. Mr. Baylies graduated from Harvard in 1884, and previously was vice-president and chairman of the executive committee of the Edison Electric Illuminating Company.

## Forty Years of Manufacturing

At the annual meeting of the General Electric Company at Schenectady, N. Y., President Gerard Swope (A'99, F'22) cut a birthday cake in observance of the company's fortieth anniversary. In April 1892, the General Electric Company was formed by the consolidation of the Thomson-Houston and the Edison General Electric companies. The figure "40" composed of ornamental electric lights decorated the top of the cake.

## Southern California Utility Pioneer Dies

On the same day that the electric utility industry in the East lost one of its leaders of long standing through the death of C. L. Edgar of Boston, Mass. (see p. 359–360 this issue) a similar loss occurred on the Pacific Coast in the death of John Barnes Miller, chairman of the board of directors of the Southern California Edison Company, Ltd. Mr. Miller, who was 62 years of age, died on April 14, 1932, at Los Angeles, Calif.

After studying at the University of Michigan, Mr. Miller returned to his native city of Port Huron, Mich., in 1890, but after a few years' business experience there and in Louisana, went to California in 1896. In 1898 he was elected treasurer of the Edison Electric Company, later the Southern California Edison Company, becoming its president three years later. After being both president and chairman of the board for many years, he resigned the former position in 1928. He was also an officer and director in several other companies, and in 1925 was elected a vice-president of the National Electric Light Association.

Mr. Miller symbolized the pioneer spirit of the West, and under his direction many small companies were consolidated and reorganized into one company noted for its soundness as well as for its ease of operation. Teamwork among employees and customer ownership of stock were encouraged, much of the pioneer work in this latter activity having been done by Mr. Miller.

## A.S.M.E. to Hold Meetings

The sixth annual aeronautic meeting of The American Society of Mechanical Engineers will be held at the Hotel Statler, Buffalo, N. Y., June 6–8, 1932. The technical program will include some 30 papers and reports covering aerodynamics, navigation, engines, airplane carriers, design, and fuel. The technical sessions will be held on Monday and Tuesday, with Wednesday open for various plant inspection trips and a sightseeing tour around Niagara Falls.

At the same time, Buffalo will be host also to the first national process meeting of The American Society of Mechanical Engineers, with technical sessions on Monday and Tuesday, and the same trip to the Falls scheduled for Wednesday.

The American Society of Mechanical Engineers, with the cooperation of the Engineering Institute of Canada, will hold its 1932 spring meeting at Bigwin Inn, Lake of Bays, Ontario, Canada, June 27–July 1, 1932. This year the scope and magnitude of the meeting will be expanded and it is expected that it will include papers illustrative of British, Canadian, and American engineering practise.

Among the special trips available is a tour leaving New York, N. Y., on June 26 and Toronto, Ontario, Canada, on June 27. At the conclusion of the convention the trip will include seven additional days by boat and railroad through some of the most picturesque sections of Canada.

## Control of Foreign Investments

Because of its importance to citizens of this country who have investments abroad, and because of its close relation to the problem of investments in engineering projects undertaken within the limits of this country, the following editorial from the April 14, 1932, issue of *Engineering News-Record*, p. 533, is reprinted herewith in full:

### "Engineering Advice Needed"

"A service to the country generally has been done by the American Institute of Consulting Engineers in a statement addressed to the Senate finance committee giving pertinent facts concerning the investment of capital in Latin America. The

Senate finance committee has been investigating conditions surrounding the investment of funds from this country in foreign fields to determine why many investments so made have turned out to be a failure. It sought to learn where responsibility for this development lay. The Institute's (A.I.C.E.) report—prepared by engineers of long experience in Latin America—places responsibility squarely on the bankers for failure to get disinterested opinion on the soundness of the ventures they were financing and to set up proper checks upon the way money was spent.

"Money has been loaned to Latin American governments in the belief that it was to be used to construct useful public works without knowledge as to the need for or revenue-producing value of the proposed works, without stipulation that the money was to be spent only upon approved work, and without providing for proper control of its expenditures. As far back as 1919 the Institute (A.I.C.E.) began urging upon American bankers the desirability of universal adoption of a practise followed by most British bankers but by only a very few in America—namely, employing independent consultants to pass upon the feasibility of projects for which they have been asked to provide funds. If after investigation the project appears attractive, British bankers do not pass out the money without stipulating that they retain control over the manner in which it is spent, and usually even over the operation of the project when completed. A second time in 1923, again in 1928, and once again in 1929, the Institute (A.I.C.E.) urged the adoption of this practise upon the principal investment houses of this country. Their warnings went without effect.

"The bankers, it appears, saw only the Institute's (A.I.C.E.) selfish interest in urging engineering investigation and control and so ignored it, being content to take any bond issue that came along regardless of its merit so long as they could make a profit out of the underwriting, passing the bonds on to the trusting public which, in the end, 'holds the bag.' The folly of that practise is now all too obvious. Much of the money so invested has been squandered on ill-conceived undertakings, investors in this country have lost or stand to lose most or all of their principal, and confidence in the banking houses that sold them the bonds has been lost. Distrust of all Latin American investments has been developed. But worst of all, international distrust and ill-will have been built up just at a time when trust and good-will are most needed.

"A frank and convincing statement of what could have been done to protect American investments abroad, even though it comes from an interested party, cannot but help to insure the adoption of sound practises in the future. The Institute (A.I.C.E.) is to be congratulated for having risked arousing antagonism among bankers in order to put the facts clearly before the public."

# Letters to the Editor

## Heart Injury From Electric Shock

*To the Editor:*

I have read the Kouwenhoven article, "Heart Injury From Electric Shock," in the April 1932, issue of ELECTRICAL ENGINEERING, p. 242–4. Are we publishing an engineering journal or a medical journal devoted to vivisection?

I deplore the efforts of Doctor Kouwenhoven to link the American Institute of Electrical Engineers with vivisection and kindred surgical work. It is not our natural field and I do not believe the rank and file of our members approve of this excursion into territory so far removed from engineering.

Yours very truly,
F. G. STRONG (A'91, F'13 and Life Member) 120 Hartford Ave., Wethersfield, Conn.

## Nerve Injuries From Electric Shock

*To the Editor:*

I should like to commend ELECTRICAL ENGINEERING for the breadth of view shown in publishing the article "Nerve Injuries from Electric Shock," in the December 1931, issue, p. 929–32.

To me the article was of great interest and I welcomed it as being a genuine contribution toward the goal of resuscitating all who are so unfortunate as to receive violent electric shocks. The more not only members of the medical profession but also the laymen like ourselves know about the physiological effects of electricity, the more successful we are likely to be in reviving a person who has received an electric shock, in case, at any time we are confronted with such an emergency.

Very truly yours,
D. W. ROSEBRUGH (A'23, M'29)
(22 Baker St., Poughkeepsie, N. Y.)

## Suggested Changes in Dielectric Nomenclature

*To the Editor:*

In the study of dielectrics, the following names are suggested as being more logical than those now in use:

1. "Capacitance factor" is proposed to replace "dielectric constant."
2. "Loss factor" is given a slightly different meaning from that previously used.
3. "Capacitivity" is suggested to replace "permittivity" in systems of units where the latter quantity is now used.

There are always objections to changes in nomenclature, especially when such changes are suggested for names of concepts of long standing. Nevertheless our language is continually changing, so that suggestions for simpler or more logical terms should be encouraged and carefully considered in order that the best possible picture of a field of study will be conveyed by the nomenclature used.

From an experimental point of view an imperfect dielectric may be represented in terms of an equivalent parallel circuit of resistance and capacitance; in fact, most determinations of the a-c. properties of dielectrics employ bridge or substitution methods of measurement in which the characteristics of the sample are measured in terms of resistors having negligible distributed capacitance and capacitors having negligible loss in series or parallel combinations. The complex expression for the experimentally determined electrical properties of the dielectric is then

$$Y = G + i\,w\,C \tag{1}$$

where $G$, the equivalent parallel conductance, is a measure of the component of current in phase with the applied potential, and therefore of the total dielectric loss by whatever mechanism it may be produced. Also $C$, the equivalent parallel capacitance is a measure of the component of current in leading quadrature with the applied potential and therefore of the total charge stored per cycle per unit potential. From a theoretical point of view, Debye ("Polar Molecules," p. 94, The Chemical Catalogue Co., 1929) has used a set of symbols from which the expression corresponding to eq. 1 is

$$Y = i\,w\,C_v\,(\epsilon' - i\epsilon'')$$

which when expanded gives

$$Y = \epsilon''\,w\,C_v + i\,\epsilon'\,w\,C_v \tag{2}$$

In this relation two new names are suggested, namely, capacitance factor, $\epsilon'$, and loss factor, $\epsilon''$; the relation between them gives the well-known and generally used quantity

$$\text{Power factor} = \sin\,[\tan^{-1}(\epsilon''/\epsilon')] \tag{3}$$

The first named or capacitance factor is defined by the relation

$$\epsilon' = \frac{C_x}{C_v} \tag{4}$$

and is the ratio of the capacitance of the sample to the capitance of a vacuum space of the same size and shape. Generally this is called the specific inductive capacity or the dielectric constant of the material, but there are two objections to the latter name, which is most commonly used: First, $\epsilon'$ is not constant, but varies with temperature because of changes in density and with frequency if the sample contains polar molecules which can move in a viscous medium. Therefore it might better be called a coefficient or multiplying factor rather than a constant. Attention already has been called to this misuse of words by G. L. Addenbrooke (*Nature*, v. 126, Nov. 22, 1930, p. 808). Second, the word "dielectric" is general whereas the word "capacitance" specifically refers to the storage of charge or the component of current in leading quadrature with the applied potential. Therefore it seems that "capacitance factor" is more descriptive of the true meaning of the quantity $\epsilon'$.

The second of the two factors or loss factor, is defined in terms of experimental data by comparing eq. 1 and 2 from which

$$\epsilon'' = G/w\,C_v \tag{5}$$

In general, $\epsilon''$ is proportional to the loss per cycle per unit volume. It may be a function of all the experimental parameters, and in no way implies the mechanism or cause of the dielectric loss, of which it is a measure. There is precedence for the name "loss factor" ("A.S.T.M. Report of Committee D-9 on Electrical Insulation," 1931, p. 93), since it has been used to express the product of the dielectric constant and the power factor in per cent.

For small loss angles power factor = $G/\omega\epsilon' C$ so that by the A.S.T.M. definition the loss factor will be the same as given by eq. 5. For large loss angles, however, my definition will have a clearer physical meaning since $\epsilon''$ is taken to measure only the loss, independent of the capacitance, whereas the A.S.T.M. definition is influenced by the capacitance because power factor is defined exactly as the sine rather than the tangent of the loss angle.

Capacitance factor and loss factor are coefficients which vary as different functions of the experimental variables, and therefore a better understanding of the electrical properties of an insulating material can be obtained by studying each separately, than by studying power factor, which according to eq. 3 involves both. For example, according to Debye's theory of polar molecules, the variation of these two factors with frequency is given by the following relations (H. H. Race, *Phys. Rev.*, v. 37, Feb. 1931, p. 441):

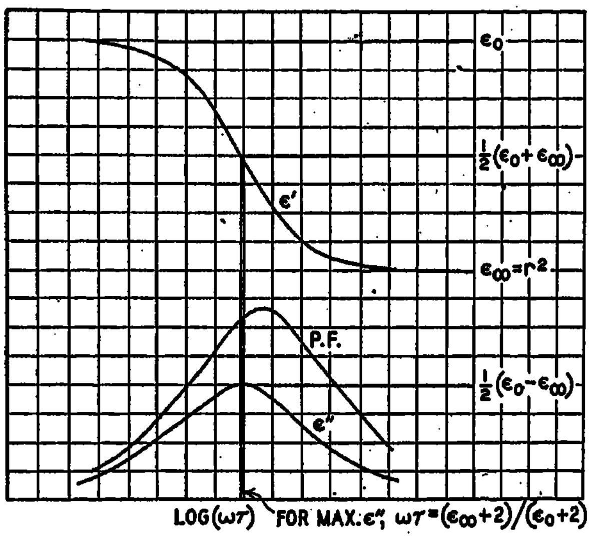
$$\epsilon' = \frac{\epsilon_0(\epsilon_\infty + 2)^2 + \omega^2\tau^2\epsilon_\infty(\epsilon_0 + 2)^2}{(\epsilon_\infty + 2)^2 + \omega^2\tau^2(\epsilon_0 + 2)^2} \qquad (6)$$

$$\epsilon'' = \frac{\omega\tau(\epsilon_0 - \epsilon_\infty)(\epsilon_\infty + 2)(\epsilon_0 + 2)}{(\epsilon_\infty + 2)^2 + \omega^2\tau^2(\epsilon_0 + 2)^2} \qquad (7)$$

where

$\epsilon'_0$ = capacitance factor at zero frequency
$\epsilon'_\infty$ = capacitance factor at infinite frequency
$\epsilon_\infty$ = (index of refraction)$^2$
$\tau$ = relaxation time

The above subscripts differ from those used by Debye and refer directly to the frequency at which the measurement is made.



Capacitance factor ($\epsilon'$), loss factor ($\epsilon''$), and power factor (P.F.) for a hypothetical polar liquid, using Debye's theory for case where $\epsilon_0/\epsilon_\infty = 2$.

To illustrate the variations of these three factors with frequency, the accompanying curves have been drawn for a hypothetical polar liquid in which $\epsilon_0 = 2\epsilon_\infty$. The power-factor curve is plotted to ten times the scale used for the other two, and illustrates the fact that this function is more complicated than $\epsilon''$ and that it is less difficult to determine the frequency for maximum loss factor than the frequency for maximum power factor as has been done by Whitehead (*Phil. Mag.*, v. 9, 1930, p. 865).

While I am discussing nomenclature for dielectrics, there is one more name which I should like to propose; the capacitance of a unit cube of dielectric is called its permittivity by some writers, but the name "capacitivity" seems much more appropriate. The word "permittance" is not in general use, while the word "capacitance" has been almost universally accepted. Therefore the capacitance per unit volume might better be called capacitivity. The accompanying table shows that this name is consistent with our present scheme of nomenclature:

| | | |
|---|---|---|
| Conductor | Resistor | Capacitor |
| Conductance | Resistance | Capacitance |
| Conductivity | Resistivity | Capacitivity |

Thus the capacitance of a homogeneous dielectric is given by the following relation

$$C = \epsilon' C_v = \epsilon'\epsilon_v(a/l) \qquad (8)$$

where $\epsilon_v$ = capacitivity of vacuum and $a$ and $l$ are, respectively, the effective area and length of the dielectric field. Thus the capacitivity of any dielectric is its capacitance factor multiplied by the capacitivity of vacuum; $\epsilon_v$ may be considered to be dimensionless and equal to unity or having both a dimensional formula and a numerical value, depending upon the system of units used. However, capacitance factor, loss factor, and power factor as defined are numerics in all systems of units.

Very truly yours,
Hubert H. Race (A'24)
(Research Engineer, General
Elec. Co., Schenectady, N. Y.)

# Engineering Foundation

## Personnel Research Federation Active

Toward meeting unemployment, the Personnel Research Federation, now over ten years old, has cooperated with agencies throughout the country by assembling and distributing information as to the methods of studying and dealing with employment. A conference was held jointly with the Social Science Research Council to determine the effects of part-time and lay-off on workers' efficiency and morale. Various other researches and investigations have been suggested and undertaken.

Continuing the investigation of causes and treatment of accident proneness on highways and in factories, a study has been made of accident susceptibility among 5,000 drivers over a 5-year period. In cooperation with the National Safety Council and other agencies, the Federation has undertaken to concentrate efforts on the diagnosis and cure of the relatively small proportion of the population who appear to be prone to accidents.

## Studies Made of Engineering Education

Studies of engineering education made by the education research committee of Engineering Foundation have been facilitated by cordial cooperation from coast to coast. Proposals for fundamental improvements are being examined by educational and engineering societies under the leadership of the Society for the Promotion of Engineering Education. Progress has been made on giving information to serve as a guide in the selection of a vocation.

A pioneer demonstration of another method was given by H. N. Davis, chairman of the committee and president of Stevens Institute of Technology. In August 1931, a camp for high school boys was conducted for two weeks, during which time simple examples of engineering and talks by different engineers were given, supplemented by a large variety of tests. The experiment was declared a success and is to be repeated in 1932.

The committee has given assistance also in the formulation of practical tests intended to appraise the qualifications of youths and men for various occupations. Other studies are receiving consideration and the committee is cooperating with the American Council on Education, and is continuing aid to the summer schools which are being conducted for engineering teachers by the Society for the Promotion of Engineering Education.

# American Engineering Council

## Pending Patent Legislation

Considerable legislation affecting the granting of patents and patent office procedure has been introduced into the present Congress. The views of American Engineering Council's patents committee have been given by its chairman, E. J. Prindle (A'06, M'20) to Congressman W. I. Sirovich, chairman of the committee on patents of the House of Representatives. Some of the more important bills, with the opinions transmitted by Mr. Prindle, are given below:

H. R. 10,152—To empower the assignees of inventor to file divisional, continuation, renewal, or reissue application. This bill is favored as an efficient simplification of procedure. The original bill has been superseded by H. R. 11,018, and slightly amended by the insertion of a clarifying phrase.

H. R. 10,153 superseded by H. R. 11,016—To limit the life of a patent to a term commencing with the date of application. Opposition to this bill was expressed because it does not give sufficient regard to the circumstances of the particular application for patents.

H. R. 10,154 superseded by H. R. 11,017—Permitting single signature in patent applications and validating joint patent for sole invention. This is considered a wise and constructive measure.

H. R. 10,155—To abolish the statute permitting renewal of patent applications. This bill was approved by Mr. Prindle, and the patents committee of the House has voted to report out the bill.

H. R. 10,156 superseded by H. R. 11,019—To limit inventors to priority of two years before filing application for patents. In effect this bill cuts down to a term substantially below two years the period in which the patentee might try out his invention on the market before applying for a patent. An extension of this limit to three years was suggested.

H. R. 10,157—To expedite prosecution of patent applications pending more than three years. This bill has been reported by the patents committee, and is supported by a special committee which carries very considerable weight and authority.

## Engineering Council Formed at Los Angeles

Local chapters of the four national engineering societies in Los Angeles, Calif., recently formed the "Los Angeles Engineering Council of Founders Societies." The preamble to its constitution is identical to that of American Engineering Council and reads: "The object of the Council shall be to further the public welfare wherever technical and engineering knowledge and experience are involved, and to consider and act upon matters of common concern to the engineering profession."

The executive committee is composed of Robert Linton, *president;* Carl Johnson (A'09, F'25), *vice-president;* L. W. Voorhees, *secretary-treasurer;* and A. F. Barnard. Among the other eight members of the council are two members of the Institute, A. P. Hill (A'23, M'29) and Prof. R. W. Sorenson (A'07, F'19).

## Muscle Shoals Bill Reported in House

A bill, No. 11,051, introduced by Representative Hill of Alabama, to provide for the leasing and other utilization of Muscle Shoals properties, in the interest of national defense and agriculture, was reported from the military affairs committee of the House of Representatives, April 4, 1932.

The measure is essentially different from the Norris bill in the Senate. It concerns all of the Government owned properties located at and near Muscle Shoals except the power plant and power generating facilities, and provides for a board of three authorized to lease and hold these properties for a period not exceeding 50 years from the date of enactment, and upon such terms and conditions as, in its judgment and subject to the limitations of the act, will best serve the interests of the United States in carrying out the purposes of this act.

**Spring Meeting of Administrative Board.**—Announcement has been made that the spring meeting of the administrative board of the American Engineering Council will be held May 13–14, 1932, at the Washington Hotel, Washington, D. C.

# Personal

W. G. Cady (M'19) professor of physics at Wesleyan University, Middletown, Conn., at a recent election of officers of the Institute of Radio Engineers was chosen to be its president. Doctor Cady is a native of Providence, R. I.; his Ph.B. degree was conferred upon him by Brown University in 1895; his A.M. the following year, and his Ph.D. was received from the University of Berlin, Germany, in 1900. For two years, he was magnetic observer of the United States Coast and Geodetic Survey, at Cheltenham, Md., the following year becoming instructor in physics at Wesleyan University, where for some time he has been in charge of all courses in electricity. His work in the piezoelectric field has been conspicuous and in 1928 resulted in his being awarded the Morris Liebmann memorial prize. This prize is an annual award made by the Institute of Radio Engineers and was made possible by a gift of $10,000 to perpetuate the memory of Col. Morris N. Liebmann, a communication engineer who lost his life in the World War; the annual accrual of interest upon this amount constitutes a cash prize of approximately $500, and the award is made for outstanding accomplishment in the field of communication. Doctor Cady has done some very important work in connection with the electric arc submarine signaling and the detection of vibrations due to feeble water disturbances. He also has contributed considerable of importance to research in both physics and electricity and has produced many valuable technical papers.

W. G. CADY

F. L. Rhodes (A'03, F'13) outside plant development engineer for the American Telephone and Telegraph Company, New York, N. Y., and through a term of service of over thirty years largely responsible for determining the present day standards of the company for outside plant construction, because of ill health retired from active service March 1932. Mr. Rhodes is a native of Boston, Mass., and obtained his B.S. degree from Massachusetts Institute of Technology in 1892. That year he entered the mechanical department of the American Bell Telephone Company of Boston and for several years was occupied chiefly with electrical measurement work relating to telephone transmission over open wire lines and cables; he also did work on the design and development of induction and repeating coils. In 1899 when the department was amalgamated with the engineering department of the American Telephone and Telegraph Company, Mr. Rhodes was chosen to specialize on the design and engineering of the outside plant of the telephone system, and in 1905 was placed in charge of the division of the engineering department responsible for the outside plant engineering. He was one of the principal members of the staff of Col. J. J. Carty. As liaison officer between the telephone companies and the electric light companies he accomplished much valuable work. He has been called upon to give expert testimony in legal cases both in the United States and Canada, and for three years served on the overhead line construction committee of the National Electric Light Association. Mr. Rhodes also has served the Institute on its board of examiners (1915–20), on its meetings and papers (now technical program) committee (1916–17), as chairman of the communication committee for a year besides serving as a member of the committee for three years; and for seven years he was a member of the standards committee.

K. B. McEachron (A'14, M'20) research engineer, L. H. Whitney (A'23) chemical engineer, and F. M. Clark (A'24) physicist, all of the General Electric Company, Pittsfield, Mass., and M. A. Savage (A'21) design engineer, and C. A. Nickle (A'25) an electrical engineer at the company's Schenectady works are participants with eighteen other General Electric employees in the 1932 award of the C. A. Coffin Foundation prize. This Foundation, established in 1922 to perpetuate the name of the founder and first president of the company, awards $11,000 annually for the most signal contributions by employees of the company toward increased efficiency or progress in the electrical art. No matter what the type of work, an employee is eligible for consideration for an award. With each prize is given a certificate of merit. Mr. McEachron received his award for outstanding accomplishment in the invention of Thyrite for use in lightning arresters; Mr. Whitney, for his valuable assistance to Mr. McEachron in this development; Mr. Clarke, for special contributions to the quality as well as reduction in cost, of capacitors; Mr. Savage, for unusual ability in the design and development of large steam driven generators; and Mr. Nickle for his exceptional ingenuity in the development of hysteresis motors of new and improved design.

J. F. Fairman (A'20, M'27) who for the past six years has been assistant electrical engineer for the Brooklyn Edison Company now has become electrical engineer for that company. His progress since joining the Brooklyn Edison Company in 1925 as assistant outside plant engineer has been marked, as was his advancement in his academic work on the teaching staff of the University of Michigan, from which he was graduated in 1918, and thereafter was first instructor and then assistant professor of electrical engineering. Following his discharge from military duty after the World War, he took the graduate student course of the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., thereafter returning to the university for further teaching.

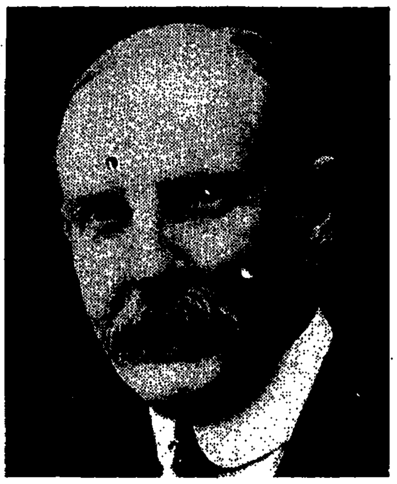
A. L. Nelson (A'16, F'29) who for twelve years has been a member of the firm of Jackson and Moreland, Boston, Mass., as well as manager of its construction department handling problems relating to plant investigation, operation, and construction, now has established a business of his own under the firm name of Arthur L. Nelson Engineers, for the same type of work as before. Mr. Nelson has served several of the engineering groups on committee work, including the A.I.E.E., A.S.M.E., N.E.L.A., and the Boston Society of Civil Engineers of all of which he is a member. From 1920 to 1924 he was on the faculty of the Massachusetts Institute of Technology, electrical engineering department, and gave lectures on power plant design, construction, and operation.

C. L. Law (A'20) general commercial manager of the New York Edison Company, New York, N. Y., now fills a similar position with the United Electric Light and Power Company, of New York. He has been with the Edison company since 1906 in various managerial capacities and received his appointment as general commercial manager in 1929. Only recently he was elected president of the Electrical Association of New York, and through his membership in other representative bodies including the American Association for the Advancement of Science, has been actively executive.

J. R. North (A'21, M'29) who has been assistant investigations engineer for the electrical engineering department of the Allied Engineers, Inc., Jackson, Mich., now has become general engineer of the Commonwealth and Southern Corporation, also at Jackson. Mr. North is serving on the foreign systems coordination committee (national) and various project committees of the joint subcommittee on development and research of the National Electric Light Association and the Bell System.

N. E. Wunderlich (A'27) engineering executive for the R. C. A. Victor Company, Incorporated, at Camden, N. J., recently established a new system for improved radio reception. This system, which bears the name of its inventor and was exhibited with success at the Chicago radio show, consists of a special yet simple circuit and a new type of tube serving the three-fold purpose of detection, amplification, and automatic volume control. Preliminary tests and measurements by two nationally recognized laboratories confirm its claims.

A. E. Kennelly (A'88, F'13, and past-president) professor emeritus of electrical engineering of both Harvard University and Massachusetts Institute of Technology, on the evening of Friday, April 8, 1932, was the recipient of another distinction in the bestowal of the Medal of Honor of the Institute of Radio Engineers, of which he is a past-president. Doctor Kennelly's achievements have been so numerous and so well known that they will not be included here. This latest citation was "for his studies of radio propagation phenomena and his contributions to the theory and measurement methods in the a-c. field which now have extensive radio application." The award itself includes a gold medal suitably engraved and bestowed annually upon "that person who has made public the greatest advance in the science or art of radio communication, regardless of the time of performance or publication of the work on which the award is based." Others who have received this Medal of Honor include Guglielmo Marconi (HM'17) M. I. Pupin (A'90, F'15, HM'28 and past-president) J. S. Stone (A'08) E. F. W. Alexanderson (A'04, F'20) Lee DeForest (A'04, F'18) and others, the first award having been made in 1918.



A. E. KENNELLY

W. I. Middleton (A'09, M'14) who has been chief electrical engineer of the Simplex Wire and Cable Company for many years, now has retired from office, completing a record of distinction. He has made many valuable original contributions to cable production and application. Mr. Middleton's connection with the company dates from 1903; his work in the cable field includes the pioneering of deep oil well cable and the all rubber covered cable design for mining service. His reputation in cable engineering is world wide.

H. V. Bozell (A'08, F'23) who has been identified for some time with Bonbright and Company, New York, N. Y., and who at one time was editor of the *Electrical World*, now has been elected executive vice-president and a member of the board of directors of the Associated Telephone Utilities Company, a holding company which through its subsidiaries operates some 909 exchanges over properties including 511,000 telephones and about 60,000 miles of toll line in 25 states of the Union.

C. R. Beardsley (A'08, F'30) has been appointed assistant to the superintendent of distribution of the Brooklyn Edison Company, Brooklyn, N. Y. Since 1923 he has been electrical construction engineer and had the supervision of the electrical construction of the Hudson Avenue power station and of substations. Also from 1928 to 1930 he was chairman of the accident prevention committee of the engineering national section of the National Electric Light Association.

F. L. Aime (A'15) an electrical engineer for the J. G. White Management Corporation, New York, N. Y., and for many years identified with the Utility Management Corporation, New York, N. Y., recently joined the staff of the consulting engineers, Gibbs and Hill, also of New York. Specifically, his new operations will include assignment to high voltage cable work in connection with the electrification which his company has undertaken for the Pennsylvania Railroad.

A. J. Gowan (A'23) now has been engaged as electrical engineer of the U. S. Army Engineer Corps., Rock Island, Ill., in charge of electrical design and installation of locks and dams in connection with the Nine-Foot Channel development on a section of the Mississippi River. He has served as an electrical engineer with the General Electric Company, Stone and Webster Engineering Corporation, and Atmospheric Nitrogen Corporation.

W. C. Mainwaring (A'22) for the past fourteen years district sales manager of the Northern Electric Company, Limited, Vancouver, B.C., has been chosen to head the merchandising activities of the British Columbia Electric Railway Company, Limited, both on the mainland and on Vancouver Island. He will bear the title of merchandising manager, a new position created by the recent rapid expansion of this department.

R. W. Shoemaker (A'07, M'19) who was at one time electrical engineer and superintendent of the electrical department of the Turlock Irrigation District, California, and more recently engaged by the Electric Bond and Share Company at Rio de Janeiro, now after a two years' stay in Brazil has returned to California to resume professional practise.

N. L. Towle (A'20, M'24) who has been assistant professor in charge of electrical laboratories at Cooper Union, New York, N. Y., now has been given charge of that institute's department of electrical engineering, with the rank of full professor

Professor Towle who has been on the staff since 1920 previously taught in the Iowa State College at Ames, Ia.

O. H. Caldwell (A'13, M'22) editor of "electronics" and "Radio Retailing," issued by the McGraw-Hill Publishing Company, New York, N. Y., and E. L. Nelson (A'20, M'26) radio development engineer at the Bell Telephone Laboratories, Incorporated, New York, N. Y., have been elected directors of the Institute of Radio Engineers to serve for the year 1932.

A. T. Perkins (M'25) president and general manager of the People's Motor Bus Company recently was elected to a two-year term of service as a member of the board of directors of the St. Louis (Mo.) Chamber of Commerce. E. B. Meissner (A'16) president and general manager of the St. Louis Car Company, also has been elected a member of its executive committee.

A. G. Richardson (A'24) who for two years was chief engineer of the Allen Hough Carryola Company, Milwaukee, Wis., and for a year after severing connections with that company, remained in Milwaukee to do experimental work for himself, using the Allen Hough laboratory, returned to New York, N. Y., December 1, 1931, to engage in radio service.

G. F. Sanderson (A'30) who has been doing engineering work for the Metropolitan Edison Company, Reading, Pa., now has become general manager for the West-Lon Light and Power Company, the Allied Vermont Utilities Company, and the Weybridge Light and Power Company, subsidiaries of the Colonial Utilities Corporation, Chester, Vermont.

E. B. Freeman (A'21) vice-president and general manager of the B. F. Sturtevant Company, Hyde Park, Boston, Mass., has been elected president succeeding former Governor Eugene N. Foss, who has been made chairman of the board of directors. Mr. Freeman's rise in the organization was from the sales engineering department.

W. J. Ducey (A'22, M'30) who was assistant electrical engineer for Allied Engineers, Inc., Jackson, Mich., now has been made the electrical engineer of Consumers Power Company at Jackson. Mr. Ducey is chairman of the overhead systems committee of the Great Lakes division of the National Electric Light Association.

S. S. Green (A'20) secretary-treasurer of the Duncan Electric Manufacturing Company, Lafayette, Ind., has been appointed chief engineer to succeed the late Jesse Harris (M'27). Mr. Green has been on the engineering staff of the company since 1929, when he first became identified with the Duncan organization.

G. J. Newton (A'10, M'15) who has been doing consulting work at Hollywood, Calif., now has removed to Youngstown, Ohio, to practise consulting distribution engineering there. Between 1916 and 1924 Mr. Newton served the Institute's power transmission and distribution committee for four terms.

R. D. McManigal (A'18) who has been serving the Westinghouse Electric Company of Japan at Tokyo as its special representative, now has been made assistant to the manager of the central station and transportation division of the Westinghouse Electric International Company, New York, N. Y.

Sidney Hosmer (A'97, F'12) who recently was made vice-president and assistant general manager of the Edison Electric Illuminating Company of Boston, Mass., now has been elected a director of the company to replace Robert Saltonstall, resigned.

R. E. Doane (M'25) who until recently was manager of the price and cost department of the Standard Underground Cable Company division of the General Cable Corporation, now has become sales engineer of the Doane and Jones Company, at Elmira, N. Y.

A. A. Leeven (A'24, M'30) superintendent of the electrical engineering department of Cia Hidroelectric Guanajuatense, S. A., in Mexico City, Mexico, was appointed division engineer of Cia Nacional de Electricidad, S. A., Torreon, Coahuila, Mexico, effective April 1, 1932.

Teruyoshi Matsuo (A'30) imperial inspector of the Japanese Navy, who has been in New York, N. Y., doing work for his government, now has returned to Japan, where he has been engaged in the capacity of electrical engineer for the Kure Kaigunkosyo Denki-Jikkenbu, at Hiroshima.

R. T. Bauschman (A'28) who was power sales engineer of the Pennsylvania Power and Light Company at Hazleton, Pa., recently was transferred to the statistical division, system operating department of that company.

M. W. Kellerman (A'29) formerly assistant general foreman of the Appalachian Electric Power Company at Welch, W. Va., now has been made rural extension engineer for the same company at Pulaski, Va.

W. S. Rollo (A'25) who has been doing engineering service for the Otis Elevator Company's Yonkers (N. Y.) works recently became connected with an English company, the Waygood Works, Ltd., in London.

Samuel Reber (A'93, F'12, and a Member for Life) general foreign representative of the Radio Corporation of America, New York, N. Y., recently was elected a director of the American-Russian Chamber of Commerce.

Emerick Toth (A'29) has left the Kolster Radio Corporation, Newark, N. J., where he was a laboratory assistant, and is now receiver engineer on high frequency circuits for Wired Radio, Incorporated, of Ampere, N. J.

J. P. Edwards (A'92, M'13) recently retired from the office of Eastern division traffic superintendent of the Western Union Telegraph Company. His term of service covered a period of some twenty years.

C. D. Taylor (M'20) who has been manager of the refrigeration department of Westinghouse Electric and Manufacturing Company, Mansfield, Ohio, now is vice-president and general manager of The Elin Company, at Philadelphia, Pa.

C. B. O'Neil (A'29) previously sales engineer for Fairbanks, Morse and Company, at Houston, Texas, now has been transferred to St. Louis, Mo., where he will be district manager of railroad sales for his company.

A. A. Armer (A'27) development engineer for the Magnavox Company, Ltd., Berkeley, Calif., now has been appointed field engineer for this company. His headquarters will be at Fort Wayne, Indiana.

T. H. Chen (A'29) who has been doing postgraduate student work at Cornell University, Ithaca, N. Y., now has returned to China where he will be identified with the Nanchang Electric Company, Nanchang, Kiangsi, China.

J. N. Barrett (A'21) in the past sales engineer for the Otis Elevator Company in the Detroit, Mich., district, now has been transferred to the company's offices at Washington, D. C.

F. I. Degen (M'24) who has been practising engineering in New York, N. Y., now has been elected vice-president of the Babcock Manufacturing Company, Leonardsville, N. Y.

R. W. Gaskins (A'24) formerly serving the Stone and Webster Engineering Corporation as engineer, has removed from Boston to join the Troy Laundry Machinery Company, East Moline, Ill.

K. Hirose (A'23) designing engineer for Shibaura Engineering Works, Kanasugi, Shibaku, Tokyo, Japan, now has been transferred by his company to Tsurumi, Yokohama City, Japan.

F. I. Morgan (A'31) who has been with the Pennsylvania Water and Power Company at Holtwood, Pa., now has affiliated himself with the Safe Harbor Water Power Corporation at Safe Harbor, Pa.

E. A. Mellinger (A'08) director of the Automatic Telephone and Telegraph Company, Chicago, Ill., recently resigned from his position on its board.

C. E. Chatfield (A'06, M'25) has resigned from the position of Chicago manager of the Lapp Insulator Company to form a sales agency at Indianapolis, Ind.

H. H. Hansson (A'29) electrical engineer for Sargent and Lundy, Inc., Chicago, Ill., now has engaged in like capacity with Motala Ström Kraft A. B., Motala, Sweden.

# Obituary

Bernard Arthur Behrend (A'00, F'12) internationally noted as an engineer and for his inventive genius, met with sudden death March 25, 1932, at his home in Wellesley, Massachusetts. He was born in Villeneuve, Switzerland, May 9, 1875, and as a boy resided in Switzerland, England, and Germany, receiving his early education by private tutelage, and through a course in the Polytechnic Institute and University of Berlin, Germany, from which he was graduated in 1894 with a C.E. degree. During the year following he was assistant to the late Gisbert Kapp, and in 1896 he became assistant chief engineer to the Oerlikon Company, Switzerland. This was immediately prior to his coming to the United States. He at once applied for citizenship and was granted naturalization in 1903. He has been non-resident lecturer at the University of Wisconsin, Leland Stanford University, McGill, and Massachusetts Institute of Technology. In 1899 he connected with the Bullock Electric Manufacturing Company, Cincinnati, Ohio, as chief engineer of its a-c. work, this office being subsequently extended to include all of the company's plants in both the United States and Canada. In 1904 the Bullock Electric company became allied with the Allis-Chalmers Manufacturing Company, Mr. Behrend continuing in the office of chief engineer of electrical departments in this company; he also established the first department in Milwaukee for the production of large units. At the end of 1908 receivers of the Westinghouse Electric and Manufacturing Company engaged Mr. Behrend and members of his staff to take charge of the power engineering departments at East Pittsburgh, Pa.; here he remained for 18 years, although devoting a large portion of his time to consulting work in Boston, Mass. Mr. Behrend has always been a prolific contributor to technical literature; his first outstanding work, "Theory of the Induction Motor (Circle Diagram)" produced between 1894 and 1896, represented one of the earliest expositions on a theory now universally applied, and used today in practically the same form in which he gave it over 36 years ago. It was chiefly the subject of his university lectures, and was published later in book form under the title "The Induction Motor," translations appearing in French, German, and some sections, even in Japanese. In 1897 he developed the theory of the regulation of alternators under inductive loads, urging its adoption for purposes of standardization. This was adopted in general as first proposed by him, although sometimes known under the name of "Potier" method; a paper before the Institute described the method in detail and recommended its standardization. Among others of his contributions are many Institute papers. In 1902 Mr. Behrend introduced the radial-slot cylindrical turbo-generator rotor with chrome nickel end rings. This unit was exhibited jointly at the World's Fair in 1904 by the Bullock Company and Hoovens, Owen, and Rentschler; it won the grand prize and Mr. Behrend was the recipient of the accompanying gold medal. The largest power unit of the exposition was a 3,500-kw. generator driven by an Allis-Chalmers engine, a product of Mr. Behrend's inventive ability. Between 1900 and 1908 he designed the electric generating units for the Kern River Power Company, the Pacific Electric Company, the Denver Gas and Electric Company, a large group of the Niagara Falls units, the receiving plant of frequency changing units at Montreal linking the Shawinigan Water and Power Company with the power plants at Montreal, the steam turbine units of the Brooklyn Edison Company and the Brooklyn Rapid Transit Company (at that time the fastest of their type). The large gas engine driven units of the Carnegie Steel Company, the Illinois Steel Company, and of the Indiana Steel Company were all of his design. In 1909 he introduced the radial slot rotor to the Westinghouse company and developed the plate rotor construction now used by the company for its largest types of turbo-generator rotors. It was a revolutionary type devised for the purpose of overcoming defects in large forgings. While engaged with the Allis-Chalmers and Westinghouse companies, Mr. Behrend took out over 80 patents. Devoted to the interest of engineering education, he organized under A. G. Wessling the first engineering training classes at Cincinnati, Ohio. He has served on many technical committees, among them the Institute's standards committee, the U. S. national committee of the International Electrotechnical Commission, the Engineering Societies Library Board, and the Edison Medal committee; he was chairman of the Institute committee on professional conduct, and electrical machinery, and was first chairman of the A.I.E.E. Section in Cincinnati. His service as a manager and senior vice-president of the Institute was over a period of five years. In 1912, for improvements on high-speed electric generators, he received the John Scott Medal; he was a member of the A.S.M.E. and the A.S.C.E. and of the Franklin Institute; a fellow of the American Physical Society, the American Society for the Advancement of Science, and the American Academy of Arts and Sciences, and a member of the Engineers' Club of New York.

Charles Leavitt Edgar (A'96, F'12) president and general manager of the Edison Electric Illuminating Company of Boston, Mass., died of pneumonia April 14, 1932, at the Marlborough Blenheim Hotel, Atlantic City, N. J. Mr. Edgar, who was in his seventy-second year, was a native of Somerset County, New Jersey. He was graduated in 1882 from Rutgers College, New Brunswick, N. J., receiving at that time the two degrees of A.B. and A.M.; his honorary degree in E.E. was received subsequently for postgraduate work at the same institution. The year following his graduation he connected with the Edison Machine Works in New York, N. Y., for nine months; then was transferred to the factory of the Bergman Company, which manufactured central station apparatus. Shortly thereafter he became connected with the Edison Electric Light Company at its original factory in New York, N. Y. This service continued until 1887, by which time he had advanced to the position of chief engineer. Most of his work had been of a general engineering character with particular reference to the installation of small central stations throughout New York and adjoining states. In the fall of the year 1887 the parent Edison company sent Mr. Edgar to Boston as superintendent of the Edison Electric Illuminating Company of Boston, which had been organized the year before; in 1889 he became general manager and shortly thereafter vice-president; and upon the death of Jacob Rogers in 1900 he was chosen president. The central station industry in this country owes much of its pioneer work to Mr. Edgar who toiled with diligent devotion to make its influence far reaching. He has made numerous trips to Europe to study first hand the methods used in the largest electric plants there, and as a result of these investigations he was among the first to appreciate the value of storage batteries as central station auxiliaries; in fact it was he who imported from Germany the Tudor battery, the first to be used in this service in this country. He also foresaw the importance of compact generating units for stations in congested districts, and installed at Boston the first vertical engines used in America for central station work. On a special visit to England in 1898 he studied the Wright demand system of charging and upon his return introduced this into the service of the Boston company. One of the features that has contributed great success to this company is its highly developed welfare work; Mr. Edgar interested himself personally in the formation of the Edison Employees' Club which gave so much impetus to similarly organized groups and later, to company sections of the National Electric Light Association in other cities. The Boston club has served as a model for many others. After being three times vice-president of the National Electric Light Association he was elected its president in 1903. He has been president of the Massachusetts Electric Light Association, at one time was chairman of the A.I.E.E. Section in Boston, and has served the Institute on the Edison Medal committee. Always a keen student of sociology and political economy in connection with modern industry, of recent years he has devoted much of his time to the affairs of the National Civic Federation, serving as a member of its committee of twenty-four, investigating the question of municipal ownership of public utilities in other countries. He also was chairman of the industrial welfare department of the federation for several years, in which work he made several surveys of the problem of old-age dependency and pensions. At the time of his death he was chairman of the board of the New England Power Association; a member of the executive committee of the Employers' Liability Assurance Corporation, Ltd.; director of the Employers' Fire Insurance Company of Boston, and of the Electrical Testing Laboratories of New York; and a trustee of the Massachusetts Utilities Associates Employers' Group Associates, and of Rutgers College, from which he received his Doctor of Science degree in 1927. He is a past-president of the Edison Pioneers and a member of Illuminating Engineering Society, The American Society of Mechanical Engineers, the Society for Electrical Development; also of the Exchange, Country, Algonquin, and University clubs of Boston, and the Engineers and University clubs of New York.

**Francis M. Hartmann** (A'02, F'14) dean of the school of engineering, Cooper Union Institute of Technology, New York, N. Y., and head of its electrical engineering department, died at his home March 28, 1932, as the result of complications which followed an operation. Dean Hartmann was born August 31, 1870, at Cochecton, New York. He attended Damascus Academy, in Pennsylvania, and New York evening high school. His B.S. degree was granted him upon the completion of a five-year course in general science at Cooper Union night school, New York, N. Y., in 1895; eight years later, by postgraduate work in physics and electrical engineering, he earned his E.E. degree. In the interim, however, he was graduated from a three-year course in chemical analysis, also taken at the Cooper Union night school, and had taken postgraduate work in physics and electrical engineering and other postgraduate work in mathematics at New York University. From 1891 to 1894 he was engaged in surveying and engineering with H. H. Spindler, for the City of New York, and from that time until 1901, Mr. Hartmann was computer in the city department of public improvement. Then he received his appointment as instructor in physics and electrical and mechanical engineering at Cooper Union for both day and night school, a position which he occupied until in 1905 he was made assistant professor of electrical and mechanical engineering, three years later to be placed in charge of the department. Paralleling a portion of this period he was working with A. G. Koenig, consulting engineer of New York; also with the E. E. Cary Company. In 1908 Cooper Union chose him chairman of the committee on promotion for three science courses; a five-year night school course in electrical engineering, a five-year night school course in general science and the day school technical science course. Dean Hartmann's contributions to technical literature have covered a variety of subjects. In 1912 he designed and equipped the new dynamo laboratories and thermodynamic laboratory for the Hewitt Memorial Building, Cooper Union. In addition to his membership in the Institute he was a Fellow of the American Association for the Advancement of Science, a member of The American Society of Mechanical Engineers, the American Physical Society, the American Mathematical Society, and the Society for the Promotion of Engineering Education.

**D. A. Wadia** (A'21) who for some time has been identified with the engineering branch of the Burma Shell Oil Storage and Distributing Company of India, Limited, St. Helen's Court, Ballard Estate, Fort Bombay, India, died at Surat on the 13th of January 1932. Of late he has been making his home with his uncle at Dadar. Mr. Wadia was a native of Bombay (1887); he held a scholarship from the Victoria Jubilee Technical Institute at Bombay, which allowed him to matriculate at the Bombay University. In 1908 he received the Victoria Jubilee Technical Institute first-class certificate with the degree of licensed mechanical engineer; he also held a certificate from the City and Guilds London Institute, department of technology, in the preliminary grade of electrical engineering, and a certificate for competency for what is there known as the Bombay Boiler Act, issued by the government. During his student days at the Victoria Jubilee Technical Institute, Mr. Wadia worked upon the erection of the institute's central power station, and prior to undertaking wiring installations for the Fazulbhoy Mills, Limited, he worked for eight months on a similar installation for D. R. Cooper and Company. As second assistant engineer, he joined the Brush Engineering Company of England, and was engaged by it in work upon the power house of the Bombay Electric Supply and Tramways Company. Another year was spent as electric foreman of the Simplex Conduits Limited. Engaged with the Tata Hydroelectric and Power Supply Company, Bombay, Mr. Wadia worked for three years upon the erection of substations. From 1914 to 1915 he was electrical supervisor for the Bombay Government Public Works Department, and for the next two years he was engaged with the Tata Hydroelectric Company as mill inspector in charge of electrically driven mills. In 1917 he entered the military works service at Karachi, assuming charge of all electrical and mechanical work in connection with machinery and shipments, erecting and maintaining the electrical installation connected with the Karachi concentration and rest camps. He also had charge of a 3-ton ice plant, both in its erection and maintenance.

**Brace Hayden Hamilton** (M'22) manager of the Washington, D. C., office of the Westinghouse Electric and Manufacturing Company, died March 21, 1932, in that city. He was born in Buffalo, N. Y., May 19, 1877, and after graduation from Cornell University with the class of 1899, he joined the General Electric Company for work on the design of d-c. and a-c. motors and generators. From 1902 to 1908 he specialized on turbo-generators and was involved in the supervision of special tools and methods essential to the construction of high speed apparatus. He also developed special designs and applications of governors and lubrication devices for turbines. Mr. Hamilton left the General Electric Company in 1909 to engage with the power division of the Westinghouse Electric and Manufacturing Co., Washington, D. C., on similar work in the design of d-c. and a-c. turbo-generators of the engine and water-wheel types. From 1910 to 1920 he worked on the design of power projects and the application of all types of power apparatus for the United States government, including the design of several complete plants. In 1917 he submitted a report to the chief of engineers, U.S.A., on the Potomac River hydroelectric development; this work was combined with laboratory experimental fixation of atmospheric nitrogen and with a study of an additional water supply for the District of Columbia. The year 1920 found him doing engineering work on generation and distribution of power from Wilson Dam, Muscle Shoals. For four years from 1917 to 1921, work on geared, electric and Diesel-electric marine drive, and auxiliaries for Navy vessels and the Merchant Marine occupied him; in fact as early in his career as when he was with the General Electric Company, Mr. Hamilton was responsible for the turbine design of horizontal turbo-generator sets for ships use.

**Jesse Harris** (M'27) who has been engineer in charge of development for the Duncan Electric Company, Lafayette, Ind., died February 15, 1932. He was born in Albany, N. Y., March 10, 1864; his schooling, the equivalent of a college education was supplemented by technical study. During the year 1888 he was engaged in general electrical contracting in Albany, and two years later entered the experimental department of the Thomson-Houston Electric Company at Lynn, Mass. In a year's time he had advanced to the position of assistant foreman of the meter department, thereafter becoming foreman of the instrument department. Returning to Albany, he was electrical engineer and superintendent of the Federal Instrument Company, and later electrical engineer of the Dongan Instrument Company. In 1907 he went to Lafayette, Ind., to develop recording instruments for the Central Laboratory Supply Company and the following year he joined the Duncan Electric Company, with which he remained for ten years as superintendent and fifteen years as chief development engineer on a-c. and d-c. meter development. Mr. Harris held twenty or more patents on various metering devices, one on a synchronous induction motor and another on a special system for operating a-c. motors from d-c. sources. He was considered a master technician in his line and did much excellent work in the correction of temperature errors in watthour meters. While with the Duncan company he was responsible for most of its design and development work.

**Thomas Foulkes** (A'08, M'13) founder of the Foulkes Electrical Company, Los Angeles, Calif., and a man who accomplished much of the pioneer work of the West in electrical engineering, died March 14, 1932, at the age of 80. He was born in England, receiving his early education in the common schools and partly at night school. He started his electrical work in the early days of the industry with the Citizens Electric Light Company, at Helena, Montana; then he spent a year with the Edison Company at Tacoma, Washington, a year with the Thomson-Houston Company, at Portland, working on the installation of isolated plants, and afterward some time with the General Electric Company. He was manager of the Baker City Electrical Light Company, Ore., engineer of the Hill House Hotel at Tacoma, Wash., and chief engineer of the Portland Hotel at Portland, Ore. He later went to southern California where in 1894 he became chief engineer of the municipal electrical plant at Pasadena. Two years later he bought an electrical business in that city, and in 1897 opened an electrical supply business in Los Angeles with a factory at Naud Junction. The factory was discontinued in 1899, and from then on the activities of the Foulkes Electrical Company were devoted exclusively to electrical engineering, design, and installation. Mr Foulkes was the first president of the Los Angeles board of public utilities.

Max Neuber (A'08, M'31) experimental engineer of the Moto Meter Gauge and Equipment Company, Toledo, Ohio, and secretary-treasurer of the Institute's Toledo Section, died April 4, 1932, at his home in that city. Mr. Neuber was born in Leipzig, Germany, and came to this country in 1889, his education including two years' schooling in Germany and six years in the public schools of Toledo, Ohio. He started to work in the factory in which his father was machinist, attending night school at the Toledo manual training school; he took up mechanical drawing and machine work also. This was followed by a correspondence course in mechanical and electrical engineering. By the time he had been in business eleven years he was operating machine works which involved a number of his own inventions, including an electric button machine and a water filtration system. Mr. Neuber leaves behind him a record of loyal service to the A.I.E.E. Section of which he was an officer, as well as an appreciation of the spirit of fellowship with which he inspired his many friends.

Marvin C. Ansteth (A'30) assistant superintendent of the western division of the Niagara, Lockport, and Ontario Power Company, Lockport, N. Y., died April 1, 1932 at Lockport. He was 36 years old and was born in Buffalo, N. Y., where he passed through elementary school and three years of technical high school. In 1915 he engaged with the Westinghouse Electric and Manufacturing Company at Buffalo, and two years later joined the Niagara, Lockport and Ontario Power Company as assistant superintendent of its Lockport-Mortimer districts. His affiliation with this company represented an uninterrupted period of service.

# Local Meetings

## Student Convention at Haverford College

The eighth annual local student convention sponsored by the Philadelphia and Lehigh Valley Sections was held at Haverford College on March 14, 1923, with eight schools participating: namely, Delaware, Drexel, Haverford, Lafayette, Lehigh, Pennsylvania, Princeton, and Swarthmore. The program of the morning session was as follows:

Thyrite Lightning Arresters, by Albert Werner, Drexel Inst.

Ship Stabilizing Devices, by W. J. Henderson, Jr., Univ. of Pa.

Solving Polyphase Problems by Symmetrical Components, by W. M. Dudley, Swarthmore Col.

Electricity in Aviation, by L. F. Underwood, Lehigh Univ.

Those attending the convention were guests of Haverford College at luncheon, afterward separating into groups, according to preference, to visit the Plymouth Meeting substation of the Philadelphia Elec. Co., high speed electric railway of the Philadelphia & Western RR. Co., Wayne Junction substation, Bell Telephone Co., and RCA Victor Co. Following dinner at the Engineers Club, Dr. W. E. Wickenden, president, Case School of Applied Science, gave an address entitled "The Engineer's Professional Status." The registration was 150.

## Future Section Meetings

**Akron**

May 10—Annual banquet and ladies' night. Human Engineering, by Dean Fred E. Ayer, Univ. of Akron. Movies.

**Baltimore**

May 20—Speaker: Dr. W. B. Kouwenhoven, Johns Hopkins Univ., vice-pres. A.I.E.E.

**Cleveland**

May 19—Subject and speaker to be announced.

**Detroit-Ann Arbor**

May 17—House of Magic, by Oliver Ajer, Genl. Elec. Co.

June 21—Spring frolic.

**Lehigh Valley**

May 13—High Voltage Cables, by D. M. Simmons, Genl. Cable Corp. Meeting to be held at Americus Hotel, Allentown, preceded by dinner.

**Louisville**

May 13—Dial Telephone Equipment in Louisville. Speaker from the Southern Bell Tel. & Tel. Co.

June 3—Recreation meeting.

**Pittsburgh**

May 10—Annual banquet and ladies' night.

**Seattle**

May 17—Address by L. Sapovi, Hooker Electro-Chem. Co.

**Spokane**

May 27—Annual dinner meeting. History of the Electrical Development of the Inland Empire, by John B. Fisken. Election of officers.

**Vancouver**

May 21—Annual outing to the Baker River Plant of the Puget Sound Pwr. & Lt. Co.

June 6—Annual dinner.

## Past Section Meetings

**Baltimore**

Some Features of Interest in Motor Driven Water Pumping Stations, by Leon Small, water engr., City of Baltimore. Dinner. Feb. 19. Att. 74.

The Naval Engineering Experiment Station, by Capt. H. R. Greenlee, director. Inspection trip through the naval station. March 18. Att. 72.

**Boston**

The Osage River Development, by A. A. Northrop, H. B. Wood, H. O. Murphy, all of Stone & Webster Engg. Corp. Motion pictures. Feb. 16. Att. 205.

Short Time Phenomena With Relation to Recent Developments in Circuit Interruption, by Joseph Slepian, Westinghouse Elec. & Mfg. Co. Films—"Pole-Pushers in Puget Sound" and "The Magic of Communication." March 8. Att. 165.

**Chicago**

The Electrical Industry of Today, by C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. Joint meeting with Western Soc. of Engrs. March 25. Att. 108.

**Cincinnati**

Steel Research in Electrical Manufacturing, by J. Fletcher Harper, Allis-Chalmers Co. Dinner. March 10. Att. 60.

Electrons at Work and Play, by Phillips Thomas, Westinghouse Elec. & Mfg. Co. Demonstrations. Joint meeting with Engrs. Club of Dayton. April 7. Att. 300.

**Cleveland**

Non-destructive Magnetic Testing of Ferrous Materials, by J. Kacmarik, Jr., student; The Practical Significance of Dielectric Power Factor, by R. W. Schindler, student; Ether Drift and Relativity, by Dr. Daynton C. Miller. Joint meeting with Case Sch. of App. Science Branch. March 24. Att. 199.

**Columbus**

Engineering in the Foreign Field, by H. W. Bibber, Ohio State Univ. Joint meeting with Engrs. Club of Columbus. March 18. Att. 39.

**Connecticut**

Air Conditioning, by E. D. Milener, Am. Gas Assn., and W. K. Keplinger, Carrier Engg. Corp. March 15. Att. 150.

**Dallas**

Underground Construction and Cable Development, H. K. Doyle, Dallas Pwr. & Lt. Co. March 21. Att. 78.

**Detroit-Ann Arbor**

Vacuum Tubes and Their Application, by E. H. Vedder, Westinghouse Elec. & Mfg. Co. Joint meeting with I.R.E. March 15. Att. 450.

**Denver**

Electric Steel, by J. E. Holtman and J. H. Spillane, Am. Manganese Steel Co. Dinner. March 18. Att. 34.

**Erie**

The X-ray in Industry, by E. W. Page, Genl. Elec. X-ray Corp. March 15. Att. 85.

**Fort Wayne**

The Industrial Applications of Vacuum Tubes, by L. A. Hawkins, Genl. Elec. Co. March 3. Att. 95.

**Houston**

High Pressure Steam System at Deepwater, by H. G. Hiebler, Houston Lighting & Pwr. Co. Inspection of the plant. March 18. Att. 84.

**Iowa**

E. O. Schreve, Genl. Elec. Co., reviewed recent advances made in the development of new products and the improvements in design and manufacture of existing apparatus. Joint meeting with Iowa State Col. Branch. March 1. Att. 58.

The Electrical Industry of Today, by Dr. C. E. Skinner, pres. A.I.E.E., assist. director of engg., Westinghouse Elec. & Mfg. Co. March 23. Att. 30.

**Kansas City**

The World of Electronics, by L. A. Hawkins, Gen. Elec. Co. Joint meeting with Engg. Societies of Kansas City. Feb. 29. Att. 810.

Surge Proof Transformers, by H. V. Putman, Westinghouse Elec. & Mfg. Co. March 18. Att. 65.

**Los Angeles**

Annual Student meeting under the auspices of the Calif. Inst. of Tech. and the Univ. of Southern Calif. Branches. Some Phases of Institute Work, by A. W. Copley, Westinghouse Elec. & Mfg. Co., vice-pres. A.I.E.E.; Electrical Dehydration, by M. S. Hodge, student, C. I. T.; Study of Pasadena Distribution, by A. Butler, L. J. Wright, E. G. Olinstud, and D. E. Batchelder, students, C. I. T.; Retardation Method of Testing Rotating Machinery, by W. W. Austin, student, U. S. C.; Mathematical Analysis of Retardation Method, by G. R. Little, student, U. S. C. Dinner. March 8. Att. 106.

**Louisville**

The following papers presented by students of the Univ. of Louisville: The Life of Steinmetz, by C. D. Eldridge; The Life of Marconi, by K. A. Dick; The Life of Faraday, by W. G. H. Stafford; Theory of Operation of the Thyratron Tube, by P. Frank; Electrical Eye by Mr. Best. Motion pictures and demonstrations. March 18. Att. 66.

**Lynn**

Miracles in Nature, by A. C. Pillsbury. Demonstrations. March 9. Att. 1200.

The Comparison of Radio Frequencies, by R. S. Davidson; Some Physical Characteristics of Parts Molded From Phenolic and Resinous Compounds, by A. White; Significance of Noise Measurements, by K. H. Pratt; Mechanical Effects of Overcurrent Current Transformers, by A. T. Sinks, all of the Genl. Elec. Co. March 23. Att. 300.

**Madison**

The Electrical Industry of Today, by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. March 18. Att. 57.

**Memphis**

Film—"All Steel Electric Welded Houses." March 8. Att. 30.

**Milwaukee**

A Modern Large Electrical Shovel, by P. S. Stevens, Bucyrus-Erie Co. Moving pictures. Feb. 10. Att. 65.

Space Cooling With Ice, by A. J. Authenrieth. Middle West Utilities Corp. Feb. 17. Att. 250.

**Minnesota**

The Electrical Industry of Today, by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. Dinner. March 21. Att. 75.

**Niagara Frontier**

High Spots in the Design of Steam Electric Power Plants, by I. E. Moultrop, Edison Elec. Ill. Co. of Boston, vice-pres. A.I.E.E. Dinner. March 10. Att. 55.

**Oklahoma City**

The Electrical Industry of Today, by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. Feb. 29. Att. 115.

**Portland**

The Trend in Power Plant Development, by W. F. Hynes, Genl. Elec. Co. March 15. Att. 76.

**Providence**

Vertical Transportation, by A. S. Noyes, Otis Elev. Co. Dinner. March 8. Att. 40.

**St. Louis**

Surge Proof Transformers, by H. V. Putman, Westinghouse Elec. & Mfg. Co. March 16. Att. 96.

**San Antonio**

Installation and Operation of Electrical Equipment on Battleships, by E. M. See, Genl. Elec. Co. March 28. Att. 18. San Francisco.

**San Francisco**

Principles of Flight and Recent Developments in Aeronautics, by Prof. E. G. Reed, Stanford Univ. March 25. Att. 68.

**Seattle**

Overseas Telephone Service of the Bell System, by W. H. Harrison, Am. Tel. & Tel. Co. Joint meeting with I.R.E. Feb. 19. Att. 250.

Timber Utilization, by C. W. Hogue, West Coast Lumberman's Association; Forestation, by Dean H. Winkenwerder, Univ. of Wash. Joint meeting with A.I.M.E., A.S.C.E., and A.S.M.E. Sections. March 21. Att. 115.

**Sharon**

The Expanding Universe, by F. C. Jordan, director, Allegheny Observatory. March 22. Att. 300.

**Southern Virginia**

Joint meeting with A.S.C.E. and A.S.M.E. Sections, and Engrs.' Club of Hampton Roads. Friday morning, Cecil Gray, chmn., So. Va. Section, A.I.E.E., presiding: History of Sound Pictures, by J. R. McLemroe, Electrical Research Products, Inc. Business meetings. Luncheon, W. P. Tunstall, pres. Engrs.' Club of Hampton Roads, presiding: Welcome address by C. B. Borland, director of Public Safety, City of Norfolk; More Landmarks for the Seafarer, by Lieut. E. B. Roberts, U. S. Coast and Geodetic Survey; News, by W. R. Harris, Norfolk Virginian-Pilot. Friday afternoon, Motor bus trip to Great Bridge, Va. Friday evening, dinner, Prof. A. F. Macconachie, Univ. of Va., presiding: E. M. Hastings, A.S.C.E., toastmaster, Water Purification and Its Relation to the Public Health, by Prof. J. H. Gregory, Johns Hopkins Univ.; Human Engineering, by G. Guy Via, Newport News Shipbuilding and Dry Dock Co. Saturday, Golf and visits to places of interest in the vicinity. March 25–26.

**Spokane**

Some Developments in Talking Pictures, by K. P. Kenworthy, student; The Calibration of a Dynatron Oscillator From Broadcast Harmonics, by M. Herr, student; Power System Frequency Control, by C. Cannon, student. Joint meeting with Univ. of Idaho and Wash. St. Col. branches. March 25. Att. 60.

**Springfield**

Development and Application of Photoelectric Cell, by A. R. Olpin, Bell Telephone Co. Jan. 11. Att. 122.

Television—Its Fundamental, Physical, and Psychological Principles, by J. O. Perrine, Am. Tel. & Tel. Co. Feb. 8. Att. 650.

**Toledo**

Inspection trip through the Rossford plant of the Libbey Owens Ford Glass Co. March 22. Att. 300.

**Toronto**

The Elevator or Vertical Transportation, by E. J. Ellis, Otis Fensome Elev. Co. Illus. March 11. Att. 59.

Electrical Features of New Plants, Mining and Smelting Division, by W. E. Gillespie, Intl. Nickel Co. April 8. Att. 57.

**Vancouver**

Carrier Current Telephony, by H. M. Van Allen, student; The Thyratron Tube, by J. W. McRae, student; Dust Precipitation by Electricity, by J. D. Mitchell, student. Joint meeting with Univ. of British Columbia Branch. March 7. Att. 57.

**Washington**

The Electrical Industry of Today, by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. Film—"Dynamic America." March 8. Att. 75.

## Past Branch Meetings

**Alabama Polytechnic Institute**

Locating Interference in Radio Receiving Sets, by Prof. J. C. McKinnon; Keeping the Right-of-Way Clear for Power Lines, by R. P. Lapsley, student. March 10. Att. 19.

History and Development of the Clock, by T. Fullau. March 24. Att. 18.

Election of officers: R. W. Wages, chmn.; C. W. Stickler, vice-chmn.; J. W. Solomon, secy.-treas. March 31. Att. 25.

**University of Alabama**

Audible Light, by J. B. Taylor, Genl. Elec. Co. Feb. 20. Att. 1200.

Discussion. March 14. Att. 12.

**University of Arizona**

History, Purposes, and Characteristics of the A.I.E.E., by Prof. J. C. Clark, counselor. Election of officers: P. F. Hawley, chmn.; B. Watkins, vice-chmn.; J. Jones, secy.-treas. Feb. 5. Att. 7.

Steinmetz, by Bruce Watkins, student. Feb. 12. Att. 6.

Faraday, by H. E. Stewart, student. Feb. 19. Att. 7.

Westinghouse, by J. Jones, student. Feb. 26. Att. 6.

Lamme, by R. H. Carson, student. March 4. Att. 9.

Discussion. March 11. Att. 8.

Diesel Engine Generating Plant of the Tucson Gas, Electric Light and Power Co., by Bruce Watkins, student. March 18. Att. 7.

**University of Arkansas**

Outdoor Lighting, by W. C. Warram, student; Amplifiers, by H. D. Albrecht, student. March 7. Att. 24.

Harmonic Analysis, by J. H. Nelson, student; Photoelectric Cells, by L. Williams, student; Commutation, by J. A. Hays, student. March 21. Att. 25.

Radio Beacons, by N. F. Bolling, student; the Permeameter, by G. G. Farris, student; Mercury Arc Lamp, by J. C. Howard; Rural Electrification, by Mr. Robinson, student; Iron Losses, by L. Hildebrand, student. April 4. Att. 24.

**Armour Institute of Technology**

Development of Underground Power Cables and Their Use by the Commonwealth Edison Co., by Herman Halperin, Commonwealth Edison Co. March 4. Att. 40.

Automatic Elevator Control, by L. O. Sinderson, Genl. Elec. Co. Joint meeting with A.S.M.E. Branch. March 18. Att. 33.

Generating Stations of the Edison Company, by E. Peterson, Commonwealth Edison Co. April 1. Att. 40.

**University of British Columbia**

Election of officers: J. W. McRae, chmn.; H. C. Freedman, sec'y. March 23. Att. 19.

**Brooklyn Polytechnic Institute**

Communication With Quasi Optical Waves, by L. DeRosa, student; Electro-Anesthesia, by A. Cross, student; The Barkhausen Effect, by H. Beckman, student; Frequency Control by Use of a Thyratron Tube, by R. Buehl, student. March 16. Att. 43.

Constant Current Transformer, by V. D'Agostino, student; Repairing a Submarine Cable, by H. Hoffman, student; The Life of Steinmetz, by L. Higgins, student. March 23. Att. 49.

**Bucknell University**

J. M. Dobbie elected chairman. March 11. Att. 12.

**University of California**

The Use of Telephone Circuits in the Transmission of Radio Programs, by I. B. Cave, Pac. Tel. & Tel. Co.; Pressure Phenomena in Oil Circuit Breakers, by E. Atkinson, student. March 10. Att. 35.

The Development of the Pit River by the Pacific Gas & Electric Co., by E. A. Crellin, Pac. Gas & Elec. Co. March 24. Att. 28.

**Carnegie Institute of Technology**

The Electrical Engineering Graduate, by A. M. Dudley, Westinghouse Elec. & Mfg. Co. March 9. Att. 17.

**Case School of Applied Science**

Non-destructive Magnetic Testing, by J. Kacmarik, Jr., student; The Practical Significance of Dielectric Power Factor, by R. W. Schindler, student; Ether Drift and Relativity, by Dr. D. C. Miller. Joint meeting with Cleveland Sec. March 24. Att. 180.

**Clarkson College of Technology**

Demonstrations. March 1. Att. 71.
Demonstrations. March 7. Att. 52.

**University of Colorado**

How Radio Has Affected Modern Property Relations, by Dean Stearns, Univ. of Col. Law Sch. March 9. Att. 30.

**Cooper Union**

Inspection tour of the East River Generating Station of the N. Y. Edison Co. February 15. Att. 12.

**University of Denver**

Advantages of the G. E. Test Course for Graduate Engineers, by M. M. Boring, Genl. Elec. Co. March 8. Att. 36.

**University of Detroit**

The Talking Movies, by C. L. Strong, Elec. Research Prod., Inc. Demonstrations. April 6. Att. 55.

**University of Florida**

The Correlation of Solar Disturbances With Radio Transmission, by J. L. Wolcott, student. March 23. Att. 17.

Films—"I See You Calling Me" and "Pictures by Wire." April 4. Att. 38.

**Georgia School of Technology**

Problems Encountered in Network Broadcasting, by J. W. Hutchinson, Am. Tel. & Tel. Co. March 22. Att. 63.

**Harvard University**

Arc Welding, by Prof. C. A. Adams. March 16. Att. 31.

Inspection trip to the L Street plant of the Edison Elec. Ill. Co. of Boston. March 29. Att. 12.

**University of Illinois**

Problems in the Operation of Distribution Systems, by L. Shapiro, Central Ill. Pwr. & Lt. Co. March 9. Att. 40.

**University of Iowa**

Advance in the Art of Steam Generation of Electric Power, by J. M. Drabelle, Iowa Ry. & Lt. Co. March 2. Att. 39.

Photoelectric Cell, by D. E. Duckett, student; Pilot Wire Transmission Regulating Systems, by W. C. Davie, student; Some Experiments Performed on Lightning, by P. A. Colony, student. March 9. Att. 36.

The Electrical Industry of Today, by Dr. C. E. Skinner, pres. A.I.E.E., and asst. direc. of engg., Westinghouse Elec. & Mfg. Co. March 22. Att. 166.

The Present Practises in the Installation of Power Cables, by W. H. Carl, student; Injuries From Surge Discharges, by J. B. Cutler, student; The Cascade Tunnel, by W. A. Benincosa, student; Telephone Repeater Stations, by A. O. Behnke, student. March 30. Att. 37.

**Kansas State College**

The Recent Supreme Court Decision and the Kansas Public Utility Commission, by Prof. R. G. Kloeffler, counselor; Electric Clocks, by Mr. Elwell, student. March 10. Att. 34. Program repeated same evening. Att. 34.

**University of Kansas**

Automatic Substations, by Prof. R. W. Warner; Crystals and Characteristics of Crystal Control Circuits, by E. Kelley, student. March 17. Att. 39.

**Lafayette College**

Frank H. Welsh elected chairman. March 11. Att. 25.

Short Wave Radio Stations, by C. Markley, student. March 17. Att. 20.

**Lehigh University**

Electrical Aids to Aviation, by L. F. Underwood, student; Engineering Education for Civic Usefulness, by O. W. Eshbach, Am. Tel. & Tel. Co. Illus. March 11. Att. 70.

**Lewis Institute**

A-C. Low Voltage Network Systems, by O. J. DeBever, student. March 3. Att. 30.

Power Development in the Chicago Area, by W. S. Monroe, Sargent & Lundy Co. March 18. Att. 175.

**University of Louisville**

Faraday, by W. H. Stafford, student; Marconi, by Mr. Sutt, student; Steinmetz, by Mr. Eldredge, student. March 14. Att. 21.

**Massachusetts Institute of Technology**

Modern Uses of Electricity in Medicine, by E. W. Schafer, student. March 15. Att. 60.

Inspection trip through the Bowdoin Square exchange of the New England Tel. & Tel. Co. March 23. Att. 25.

Vertical Transportation, by H. S. Duncan, student. Dinner. March 30. Att. 35.

**Michigan College of Mining and Technology**

Electricity in the Army, by C. W. Ball. Prof. G. W. Swenson, counselor, gave a report of the A.I.E.E. winter convention held in New York. March 3. Att. 20.

**University of Michigan**

The Place of Organized Research in Modern Industry, by R. Foulkrod, Michigan Bell Tel. Co. March 3. Att. 60.

Radio Experiences With Garwood, by E. B. Etchells, student. March 24. Att. 10.

Films—"Automatic Arc Welding," "Automatic Substations" and "The Greater Campus." April 5. Att. 40.

**Milwaukee School of Engineering**

Progress Made in Communication to Automobiles by Radio, by H. Wareing, Milwaukee Police Dept. March 9. Att. 94.

**Missouri School of Mines and Metallurgy**

Motion pictures. March 9. Att. 13.

Exhibits. March 18. Att. 150.

Dynamometer, by Joseph Worley, Emerson Elec. Co. April 1. Att. 25.

**Montana State College**

A New Oscillator for Broadcast Frequencies, by Carl Wall; Means of Photographing Oscillograms, by R. Wells; Reducing Transmission Line Radio Interference, by R. Wyman; Transmission and Lighting Studies, by H. Bowman; Electricity From the Sun, by J. Cromer; Two Way Television, by T. Degenhart; all students. Feb. 11. Att. 94.

Electrification of Steam Railroads, by P. Alfers; Safety in the Air, by L. Eisele; Electrified Ice Plant, by C. L. Grebe; Teletypewriter Service, by M. Hilden; Floating Motor Drive Base, by G. Huizings; Achievements in Electrical Engineering in 1931, by J. D. Mathews; A Floating Electric Power Plant, by G. Misevic; Photoelectric Control, by J. Norlin; all students. Feb. 18. Att. 95.

**University of Nebraska**

Airships and the U.S.S. Akron, by V. R. Jacobs, Goodyear Zeppelin Corp. Motion pictures. March 23. Att. 175.

**Newark College of Engineering**

Carrier Currents, by C. H. Stephan, student; Electrically Driven Ships, by W. Arnott, student; Mercury Arc Rectification, by J. Hoerter, student. March 14. Att. 24.

Telemetering, by W. DeRitter, student; Synchronous Reproduction of Sound, by W. H. Gaeckler, student; X-rays, by H. Dorhmann, student. March 28. Att. 16.

**College of the City of New York**

Vacuum Tube Applications, by W. C. White, Genl. Elec. Co. March 10. Att. 150.

Oil-Electric Locomotives, by Mr. Garrison, Ingersoll Rand Co. March 17. Att. 34.

Power House Design, by Mr. Warren, Genl. Elec. Co. Illus. March 24. Att. 27.

**North Carolina State College**

Broadcasting, by H. K. Carpenter, mgr. radio station WPTF. March 1. Att. 30.

**University of North Dakota**

Discussion and motion pictures. March 16. Att. 12.

Electric Arc Welding, by R. D. Florance, student; Remote Wattmeter Reading, by D. F. Field, student. March 30. Att. 16.

**Northeastern University**

Engineering in Japan and Korea, by Prof. A. E. Kennelly, Harvard Univ. Refreshments. March 23. Att. 76.

**Ohio State University**

Election of officers: Len Winkler, chmn.; Charles McCarty, secy.-treas. March 10. Att. 25.

**Oklahoma A. & M. College**

Noise Induction Demonstrations, by C. E. Bathe, Okla. Gas & Elec. Co. and E. B. Jennings, Southwestern Bell Tel. Co. Feb. 1. Att. 14.

Experiences Since Leaving College, by Mr. Bonar, supt. of power plant on college campus. Feb. 29. Att. 20.

Battleships—Their Construction and Special Features, by G. W. Whiteside. March 14. Att. 25.

**Oregon State College**

Safety Education of Engineering Students, by Walter Smith, Mountain States Pwr. Co.; First Aid in Industry, by F. P. White, Mountain States Pwr. Co. Feb. 25. Att. 28.

**Pennsylvania State College**

The Klydonograph and Its Use in Measuring Lighting Surges, by C. E. Laedlin, R. J. Maynard, and J. W. Hostetter, students; Study of Commutator Ripples and Their Effects, by R. Carlson and D. H. Smith, students. March 18. Att. 44.

**University of Pittsburgh**

Recent Developments in Science, by L. Colton, student. March 3. Att. 122.

Economics of Electrification, by Dr. Fitzgerald, Western Maryland R.R. March 10. Att. 116.

Musical program. March 17. Att. 120.

Alternating Current Electrification of Railroads, by H. M. Blackburn, student. March 31. Att. 124.

**Pratt Institute**

Gyro-Stabilizers, by G. H. James, student. March 17. Att. 62.

Employment of Pratt Graduates, by H. P. Miller, instructor. March 31. Att. 75.

**Rensselaer Polytechnic Institute**

Recent Developments in Oscillographs, by A. D. McAffer, Genl. Elec. Co. Demonstrations. Feb. 23. Att. 40.

**Rhode Island State College**

Growth of the Electrical Industry, by Prof. A. E. Watson, Brown Univ. March 3. Att. 21.

Photoelectric Cell, by J. F. Schmidt, student; Experiments Performed on the Banking of Transformers, by G. E. Andrews, Jr. and E. H. Long, students. March 17. Att. 18.

Business meeting. March 31. Att. 9.

Election of officers: L. M. Lang, chmn.; J. P. Costanza, vice-chmn.; W. J. Daly, secy.-treas. April 7. Att. 12.

**Rice Institute**

Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co., outlined the present status of the electrical engineering field. Dinner. Feb. 24. Att. 43.

Problems Encountered in Constructing a Television Transmitter, by F. Kennedy, student. March 9. Att. 22.

**Rutgers University**

Harmonic Analysis Via Fourier Series, by F. P. Fisher, student. March 8. Att. 15.

The Theory of Magnetization and Related Phenomena, by C. I. Bradford, student. March 15. Att. 15.

**University of South Carolina**

The Engineer's Job in Times of Economic Depression, by C. H. Moorefield. Joint meeting with A.S.C.E. Branch. March 17. Att. 101.

Coordination of Light and Music, by W. J. Valentine, student; Is the Steam Train Engine Doomed? by W. G. Shannon, student; Electronic Equipment in Train Control, by A. G. Daniels, student; Life and Works of W. S. Lee, by G. W. Arrants, student. March 23. Att. 31.

Methods of Welding, by J. R. Hopkins, student; Corona Losses, by W. V. Farnum, student; Seeing the World With a Flying Camera, by T. K. Swygert, student; Cable Sheath Corrosion in Underground Conduits, by C. L. Bradley, student. March 30. Att. 36.

Business meeting. April 7. Att. 14.

### South Dakota State School of Mines

H. L. Fry elected chairman. March 23. Att. 32.

Inspection trip through the Homestake mine. March 28–29. Att. 36.

### University of Southern California

Theatrical Illumination, by L. O. Nauman, Otto K. Olsen Elec. Co. Feb. 17. Att. 31.

Thermionic Vacuum Tubes and Their Application to Industry, by W. A. Grimes, Westinghouse Elec. & Mfg. Co. Feb. 24. Att. 25.

Discussion. March 2. Att. 18.

### Stevens Institute of Technology

Modern Developments in Organic Chemistry, by Prof. F. J. Pond. Luncheon. March 15. Att. 38.

### Syracuse University

Protective Relays, by L. M. Kenan, student; Lightning, by F. J. Conklin, student. March 4. Att. 21.

Sound Detection in Water, by H. Francis, student; Demonstration of Television Apparatus, by P. Magee, student; Electrical Power Consumption During Depression, by F. T. Burroughs, student. March 18. Att. 21.

The Jet Rectifier, by A. B. Rowley, student; Demonstration of Ability of Insulation to Withstand High Voltage, by M. E. Hogan, student. March 25. Att. 21.

### University of Tennessee

Pyrometry, by P. M. Bell, student. Jan. 28. Att. 36.

Electric Pye, by C. McCord, student. Feb. 11. Att. 47.

Audible Light, by J. B. Taylor, Genl. Elec. Co. March 11. Att. 410.

### Texas A. & M. College

Power Rates, by J. H. Johnson, student. March 10. Att. 20.

Electrical and Industrial Development of Southwest Texas, by I. Uhr, Genl. Elec. Co. March 24. Att. 85.

### Texas Technological College

Railway Electrification, by T. Haymes, student; Engineering as Related to American Industry, by H. Gray, student; The Life of Michael Faraday, by J. P. Conner, student. March 23. Att. 20.

The Financial Structure of a Utility Company, by H. D. Woods, Texas Utilities Co. April 6. Att. 26.

### University of Utah

Effective Illumination, by L. B. Gawan, Utah Pwr. & Lt. Co., assisted by C. L. Ellerbeck of the same company. March 4. Att. 103.

### University of Vermont

Prof. Buchanan outlined the uses of the oscillograph in detecting disturbances in power systems. March 7. Att. 16.

The Use of the Inverter in Power Transmission, by G. W. Patterson, student. March 21. Att. 16.

### Virginia Military Institute

The Evolution of the Dial Telephone, by T. H. Harrel, student; The Development of the Telephone, by J. S. Lay, student; The Measurement of Frequency, by G. S. Bernard, student; The Development and Use of the Photoelectric Cell, by H. L. Woodson, student. Feb. 27. Att. 72.

### Virginia Polytechnic Institute

Three Power Locomotives, by W. P. Swartz, student; Development of Electrical Power at the Conowingo Power Plant, by R. B. Poque, student; New Telephone Cable, by E. W. Seay, student; Thomas A. Edison As a Man, by N. C. Smoot, student. April 7. Att. 24.

### Washington State College

Dean H. V. Carpenter, vice-pres. A.I.E.E., presented a report of the A.I.E.E. winter convention held in New York. March 11. Att. 17.

Water Power Frequency Control, by C. Cannon, student; Talking Picture Development, by K. P. Kenworthy, student; The Calibrations of the Dynatron Oscillator, by M. Herr, student. Joint meeting with Spokane Sec. and Univ. of Idaho Branch. March 25. Att. 57.

### Washington University

H. Van Bodelschwingh described the educational system used in Germany. Feb. 18. Att. 35.

Discussion. Feb. 26. Att. 70.

### West Virginia University

Westinghouse Electric & Mfg. Co., by E. D. Harris; Colfax Power Plant, by O. B. Spangler; The Mesta Machine Co., by L. Palmer; Carnegie Steel Co., by C. E. Higgins; Development of the Steam Turbine, by F. Q. Brown; Carnegie Steel Co., by G. E. Hervey; Powdered Fuels and Ash Precipitation, by C. B. Withers; all students. April 5. Att. 29.

### University of Wyoming

A Study of Filter and Rectifier Assembly, by F. Wickenkamp, student. March 29. Att. 9.

# Employment Notes

## Of the Engineering Societies Employment Service

## Men Available

### Design and Development

ENGR., 31, 12 yr. Bell System, government plant and field experience on sound picture, radio and telephone (manual, dial, repeater, and carrier current) systems. Design and development of manual and automatic elec. testing equip. Industrail applications of electron tubes. Available immediately. C-9376.

E.E. GRAD., 28, married, desires position in design and development or teaching. One yr. Westinghouse student course; 6 months' Westinghouse design school; 1½ yr. design of industrial motors. Available at once. Location, U.S. C-5051.

ELEC. DESIGNER-ENGR., 27, single, 8 yr. experience in design of complete elec. systems including equip., signals, lighting, elevators, telephone, and miscellaneous secondary systems for New York high office bldg. Writing elec. and elevator specifications. Responsible, capable asst. to engr. Desires position with consulting engr. firm. Available at once. D-586.

E.E., tech. grad., 10 yr. experience d-c. substation design. Thorough knowledge of mercury arc rectifiers and rectifier substations, expert draftsman, knowledge of radio, inventor. Available immediately. East preferred. B-7332.

E.E. GRAD., 37, single, citizen, desires position with engg., mfg., or utility. 6½ yr. in pwr. plant and substation design. 2 yr. elec. furnaces. G.E. engg. courses. Available on short notice. C-2710.

DESIGN ENGR., col. grad., 38, married, citizen; 15 yr. engg. experience including 6 yr. generating plant and substation design, and 3 yr. field experience as tester and supervisor. Desires position with utility, engg., or construction firm. Available immediately. Location, immaterial. D-482.

### Executives

E.E. GRAD., 41, married, E.E., A.M., 12 yr. experience test dept. of large utility. 11 yr. teaching experience in evening engg. schools; 3 yr. design and manufacture of off-peak elec. storage type water heaters; analysis of load curves with a view of improving load factors. Location, immaterial. D-575.

E.E. GRAD., M.I.T., 35, married, 10 yr. experience Gen. Elec. Co. design and development of elec. measuring devices, desires position with holding company, utility or mfg. concern involving exec. and engg. ability. Immediately available. D-607.

E.E. GRAD., married, 36, 12 yr. experience in operation of elec. stations load dispatching and maintenance work. Would like position with utility company on station operating or system operation. D-611.

GRAD. E.E., 50, married, 25 yr. elec. and mech. experience, pwr. plants, concentrating and chemical plants, design and construction on pipe lines, pumps, conveyors, bldg. quarries, elec. mchy. repairing, pwr. plant and hydroelectric and pumping plant design and operation, steel drum mfg. equip., also teaching mech. engg. A-3651.

E.E. GRAD., 31, single, 9 yr. experience with elec. ry. Experience in executive and construction work. Desires connection with future. Available for work anywhere. D-643.

EXEC. ASST., tech. col. grad., 37, 12 yr. diversified experience in all branches of the utility business. Valuation work, rate investigation, cost analysis, statistical and financial research, engg. and sales work. Services offered to a company which can use to advantage a trained utility man. B-9782.

EXEC. ENGR., 41, M.E. and E.E. apprenticeship training. Mgmt. problems, industrial mfg. and utilities. Operation, design, and construction, mchy., pulp and paper, mining and concentration mills, elec., gas, water, and refrigeration system. Industrial engg. and cost accounting, production, waste-incentive system, reorganization work, scheduling, production, budgeting, sales. B-7944.

E.E. GRAD., 37, single, 15 yr. experience, covering pwr. station, substation, telephone equip., and elec. motor design, elec. motor, generator, and transformer test including development, mfg., and service test. 1 yr. postgraduate course on powr. factor, short-circuit, and transmission line calculation. Available now. Location, immaterial. D-637.

GRAD. ELEC.-MECH. ENG., 38, desires connection with utility or industrial firm on pwr. station operation as an engr. or asst. to an exec. 10 yr. experience in pwr. plant test, operation, design, construction, and maintenance. 3 yr. elec. engg. for industrial firms. 2 yr. asst. to pwr. engr. B-8379.

E.E., Univ. of Ill., 17 yr. experience covering design, construction, operation of steam, Diesel and hydro plants and elec. pumping stations. Records show lowered costs and improved service. Good organizer and economical. Fluent Spanish and French. D-660.

E.E. GRAD., 29, married, 7 yr. broad experience, pwr. house, substation, and transmission line design; major apparatus application, cost estimate, and equip. specifications. Excellent references. Desires connection with holding company, utility, or mfr. Location, South or East preferred. D-678.

E.E. GRAD., 1924, Univ. of Md., married, 8 yr. gen. experience in construction, design, and layout of substations for a large utility. Special experience in relay protection. Available in 6 wk. D-701.

E.E., 38, married, with 13 yr. experience signal and communication systems. Experienced inspection supervisor, methods engr., estimator, development and equip. engr.; 6 yr. experience as supervisor. 5 yr. tech. col. Available at once. C-2982.

E.E., 35, married, 3 yr. central station engg. proposals, sales construction. 7 yr. pwr. and industrial station wiring diagrams, conduit layouts, substation design, automatic, and supervisory equipments, rr. electrifications. Foreign languages. Available on short notice. Location, immaterial. D-710.

E.E. AND M.E. GRAD., married, 22 yr. experience, designing, construction pwr. plants, substations, transmission, distribution system, industrial plants. 3 yr. charge purchasing engg. equip., foreign interests. 3 yr. exec. experience charge engg. dept. large utility syndicate. Languages, English, German, Russian, Armenian, and Turkish. Available immediately. D-84.

GRAD. ENGR., 30, married, 2 yr. telephone switchboard testing, 1 yr. shop mech., 1 yr. municipal engg., 2 yr. designing and drafting for large copper smelter, last 3 yr. designing and drafting for large oil refinery. Desires position as asst.

to dept. head. Go anywhere. Pacific Coast preferred. C-4015.

E.E. GRAD., married, 37, wide experience in industrial plant elec. construction and maintenance; desires position in plant engg. with future. D-734.

TELEPHONE ENGR., 30, univ. grad., 10 yr. experience in design of outside plant, maintenance and specifications. Bell and independent experience. Successful in handling men. Desires opportunity with operating or holding company. D-736.

GRAD. E.E., 34, married, 10 yr. practical automotive maintenance. G.E. Test. 3 yr. designing industrial motors, d-c. arc welding equip. 3 yr. developing, designing transportation motors, control. 3 yr. automotive maintenance engg. with large bus, cab company. Interested in elec. automotive engg. D-95.

E.E., 33, married, desires position, mfr. of radio or public address systems, broadcasting station, or carrier dept. of elec. pwr. company. 4 yr. design, construction, operation, testing of equip. for elec. pwr. stations. 6 yr. installation, wiring, testing radio broadcast, tel. and tel. repeaters and carrier equip. Excellent references. D-733.

E.E. GRAD., 1924 M.I.T. cooperative, 30, married. G.E. Test; 5 yr. designing and application engr., ry. motors and equip., 2 yr. asst. to work-production mgr., in charge of all large apparatus contracts. Desire engg. or administrative position with mfr., utility or engg. firm, or teaching. Available immediately. D-760.

### Foreman

FOREMAN OR CHIEF ELECTRICIAN, expert, armature winding, motor repairs, and trouble. Install wiring systems for light and pwr. Extensive practical experience. D-657.

### Instruction

E.E. PROF., B.S. and E.E., 33, married, 2½ yr. G.E. Co., 5 yr. with utility, 4 yr. teaching, 1 yr. as acting head of dept. Desires change. Location, South or Middle West preferred. C-7152.

DIRECTOR OF EDUCATION AND TRAINING with natl. tech. corp., formerly asst. prof. of E.E., B.S. and M.S. in E.E. Experienced in exec. and administration phases of educational work. Desires position as prof. or assoc. prof. of E.E. Location, immaterial. C-8967.

GRAD., E.E. 36, 8 yr. construction, maintenance large and small pwr. plants in this country and abroad. 4 yr. mech. production design including gas engines. At present doing grad. work Univ. of Calif. Desires instructorship, elec. mech. engg. with opportunity for research. Pacific Coast, South preferred. Available June. D-639.

E.E. GRAD., 28, married. B.S. Wash. Univ., desires position teaching mathematics, E.E. subjects or lab. work. 3 yr. design street lighting, 3 yr. selling elec. instruments and substation equip. Location, immaterial. D-688.

E.E. GRAD., 1929, single, 26, now attending leading eastern univ. working for M.S. in E.E. 15 months G.E. Test course including rectifiers, industrial control, research, ry. equip., motors, shop and elec. construction experience before graduation. Desires position, utility, mfg. or teaching. Available June. Will go anywhere in the U.S. C-9003.

GRAD. E.E., M.I.T. 1920, 35, married. Entire experience since then in E.E. teaching and industrial work. Good ability and personality. Desires work in E.E. teaching. Salary open. C-2826.

CORNELL GRAD., E.E. in 1929. Has had 2½ yr. experience in design and manufacture of automatic temperature control equip. for oil refineries and regenerative furnaces. Some experience in tutoring and teaching. Desires position with mfr. of automatic control equip. or as an instructor in college. D-690.

PROF., ASSOC. PROF. E.E., 39, B.S. and E.E., Univ. of Colo. Practical experience with pwr., telephone, mining, and elec. mfg. concerns. 6 yr. on the E.E. faculty of state school. Now employed but available for school year. C-5021.

INSTRUCTOR OR ASST. PROF., 38, 8 yr. instructor in E.E., radio, physics in univ.; 5 yr. commercial experience, lighting, pwr., and radio installations, research, and design. At present research assoc. in physics in post grad. school of well known univ. Available for next September. C-6302.

DEAN OF ENGG. Mature engr.-teacher, 10 yr. experience, engg. faculties, followed by 15 yr. extensive experience engg. practise. Would consider position as dean of engg. in institution where recognition of present day needs, and ability to meet these needs is desired. Full details supplied, or personal interview arranged upon request. C-6733.

FORMER CORNELL INSTRUCTOR IN MACHINE DESIGN for 4 yr. M.E. and E.E. grad. Allis-Chalmers designer and checker 5 yr., shop apprenticeship and miscellaneous experience. 32, single. Desires teaching or engg. opportunity. Salary open. D-122.

PROF., E.E., Ph.D., 44, 8 yr. excellent teaching experience as well as practical engg. experience. B-660.

GRAD., with Master's deg, 29, married, now substation design engr. for southwestern pwr. company. 5 yr. tech. experience, 7 yr. teaching experience in college physics and mathematics, desires teaching or research position. Best of references. Preferred location, Pac. coast, but any considered. Available on short notice. D-746.

E.E. GRAD., Midwestern col., 1931, single, 24, American. Excellent scholastic record. Desires teaching opportunity. Will teach E.E., mathematics, or mechanics. Location, immaterial. D-570.

INSTRUCTOR, now teaching engg. physics, wishes to locate with school or as private tutor for the summer. Permanent position would also be considered. Well versed in the practical side of engg., and in such extra-curricular subjects as photography, dramatics, and nature study. C-9916.

E.E. GRAD., 1929, G.E. Test experience including work in radio and vacuum tube engg. dept., and with all types of elec. mchy. Will receive M.S. this June. Desires a teaching or engg. opportunity. C-1879.

MECH.-ELEC. ENG. grad., 37, married, 10 yr. experience, design and maintenance of telephone and pwr. circuits with Western Elec. and operating companies. 4 yr. experience, teaching and research work in elec. engg. 2 yr. experience, sale of Diesel and Diesel elec. pwr. Location preferred, eastern. Salary open. Available immediately. C-6340.

### Junior Engineers

1932 GRAD., 24, married. Wants a job now. Far West only. D-612.

E.E. GRAD., 1930, single, 24, 18 months G.E. Test and service shop experience. Some calculating and drafting. Good student record, ambitious, reliable. Desires position with utility or industrial concern. Prefer South West or Far West. Available immediately. D-628.

1931 E.E. GRAD., Clemson Agri. Col., 25, single, Desires work with utility, mfg. concern or construction corp. Available immediately. Location, immaterial. D-400.

E.E. GRAD., 1929, 25, single, 2½ yr. experience in design and engg. of high tension outdoor and indoor substations. Desires position connected with hydroelectric development. Location desired, South. C-5967.

E.E. GRAD., 1931, Univ. of Wis., 26, single, 10 months' experience in utility construction; 2 yr. machine shop and garage. Interested in television. Location and salary immaterial. Available at once. D-640.

GRAD. E.E., 26, married, B.S. with honors 1930. 1 yr. experience with utility as a student cadet; 6 months' experience testing and treating boiler feedwater. Desires position with utility, operation or construction or with a radio mfg. company. D-673.

GRAD. E.E., Columbia Univ., 1932; single, 23, 4 yr. with research dept. of Bell Tel. Lab.; wishes to teach E.E. subjects, either full time, or part time, research or study, to obtain Master's deg. Location and salary immaterial. Available June. D-652.

GRAD. E.E., 1929, 8 months' G.E. Test, motors, generators, industrial control, vacuum tubes; 1 yr. inspection of engravings and electrotypes in pre-make-ready dept. of progressive publishing company, partly analysis. Vacation experience surveying transmission line and sewer construction. Desires work under engr. C-7975.

E.E. GRAD., June 1932, Georgia Tech, 24, single, experience in amateur radio, radio sales, and service, bookkeeping. Desires position in any E.E. field. Location, immaterial. Available after June 6, 1932. D-683.

E.E., grad. 1928, married, 3½ yr. industrial testing experience, particularly in motor and control; also civil engg. and supervisory experience. Not afraid of responsibility. Desires a position with future. Location, immaterial. C-9568.

E.E. GRAD., 27, married. Design of pwr. plant, substation, and pwr. transmission lines. Industrial remote control. Also broad experience on appraisals of utilities. Available immediately. Location, immaterial. D-679.

E.E. GRAD., 1929, single, 23, 15 months student engr. on G.E. Test. Some test, drafting, and switchboard construction experience before graduation. Interested in position with a firm doing consulting or construction work or with utility or mfr. Available at once. Location, anywhere in U.S., New England preferred. C-8028.

GRAD. E.E., 22, single, Univ. of North Carolina, 1931. Extra study liberal arts and commerce schools. Desires position any engg. field, preferably telephone work. Four summers experience Ill. Bell Tel. Co., installation and maintenance. Salary immaterial at start. Any location either foreign or U.S. acceptable. Available immediately. D-527.

1931 GRAD. E.E., M.S. of large cooperative school, 24, single with dependents. Experience includes machine shop, drafting, clerking, armature winding, research assisting, and general maintenance and test experience with pwr. co. Desires position teaching elec. subjects, mathematics, mechanics, drawing or physics anywhere in U.S.A. Also interested in research. D-72[illegible].

GRAD. E.E., 1931, U. of M., single, 22, 7 months' student sales engr. Wagner E. Test; 9 months' experience elec., maintenance and construction of industrial equip., Ford Motor Co., 6 months' salesman. Desires position, elec. motor industry, or utility with opportunity for advancement. Location, Mich., and adjacent states preferred. Available immediately. D-719.

JR. ENGR., E.E. GRAD., V.P.I. 1930, 24, 1½ yr. experience as utility engr. with large engg. corp. References. Desires connection with large mfg. plant, electrochemical corp. or utility corp. Anything considered. Available immediately, Location, immaterial. D-735.

1931 GRAD. E.E. from leading college in N. Y. State, 25, desires position in the elec. industry. Experience main motive. Several languages. Location U.S.A., foreign. Available immediately. D-164.

1931 E.E. GRAD. Mid-West univ., 23, single, 3 months' experience with large utility. Desires position with any mfg. firm or utility. Best of references. Location, immaterial. C-9984.

E.E. GRAD., 1931, cooperative, single, 25, American citizen. Tech. high school education in France. Fluent French; some German and Spanish. Experienced in radio and sound research. Training in pwr. and commercial engr. Available at once. Location, immaterial. D-743.

## ENGINEERING SOCIETIES EMPLOYMENT SERVICE

57 Post St.
San Francisco

205 West Wacker Drive
Chicago

31 West 39th St.
New York

MAINTAINED by the national societies of civil, mining, mechanical, and electrical engineers, in cooperation with the Western Society of Engineers, Chicago, and the Engineers' Club of San Francisco. An inquiry addressed to any of the three offices will bring full information concerning the services of this bureau.

**Men Available.**—Brief announcements will be published without charge repeated only upon specific request and after one month's interval. Names and records remain on file for three months, renewable upon request. Send announcements direct to Employment Service, 31 West 39th Street, New York, N. Y., to arrive not later than the fifteenth of the month.

**Opportunities.**—A weekly bulletin of engineering positions open is available to members of the cooperating societies at a subscription of $3 per quarter or $10 per annum, payable in advance.

**Voluntary Contributions.**—Members benefiting through this service are invited to assist in its furtherance by personal contributions made within 30 days after placement on the basis of 1.5 per cent of the first year's salary.

**Answers to Announcements.**—Address the key number indicated in each case and mail to the New York office, with an extra two-cent stamp enclosed for forwarding.

E.E. GRAD., Feb. 1932, Univ. of Mich., single, 24. Special training in illuminating engg., experience as electrician and contractor. Perfect knowledge of Russian and advanced German. Citizen of U.S. Salary and location immaterial. Available immediately. Recommendations. D-744.

E.E. GRAD., 23, Sc.M. M.I.T., Harvard 28; will receive Sc.D. M.I.T. June '32; single, 38; 8 yr. practical experience pwr.-business and communication engg.; 2 yr. testing course. Recently made valuable contribution to knowledge network synthesis.—Speaks Swedish, English, German. Reading knowledge French. Desires position, well-known organization preferably communication engg. Available. D-747.

GRAD. E.E., 24, single. Wants any position in a utility, with opportunity to prepare for advancement second in consideration to salary. Location, immaterial. Available immediately. Experience as meter tester, lineman, appliance sales and service man, draftsman, and asst. to dist. engr. C-9957.

E.E. GRAD., 1930 Columbia 6 yr. course, 25, single, $1\frac{1}{2}$ yr. with Paramount Publix Theatre Construction. Knowledge sound and projection equipment, drafting, supervision of construction and layout; instruments, foundry and pattern shop methods. Desires connection, any engg. capacity. Available immediately. Present location New York, but willing to go anywhere. C-7239.

GRAD., Mechanics Inst. 1926, 25, single. Experience. 1 yr. designing pwr. and substations; 3 yr. operation and control engr. utility; 2 yr. switchboard engr.; temporary position 5 months, elec. instructor, techn. school. Engg. or teaching position desired. Location, U.S.A. or Canada. D-741.

1931 GRAD., Brown Univ., experience in publication work, editorial and advertising. Good mgr. Stresses personal side of engg. Specialized knowledge of d-c. and a-c. mchy., transmission lines, auxiliary apparatus, testing, and application. General knowledge of drafting, hydraulics, mechanics, thermodynamics, and structures. Clever, industrious, and dependable. D-742.

E.E. GRAD., Univ. of Mich. 1930, 27, single, 2 yr. experience utility distribution engg., desires position in utility or engg. company. Available on short notice. Location, immaterial, domestic or foreign. D-740.

E.E. GRAD., 1930, 23, single, 15 months on G.E. Test, on ry. equip., rectifiers, industrial apparatus, industrial control, and refrigeration development. Desires position with utility or mfg. concern. Available at once. D-409.

E.E. GRAD., 1928, married, 29. Desires work on radio or photophone equip. Experience; 2 yr. installing and servicing X-ray and physical therapy equip.; 1 yr. research and development on speakers, auditorium, and photophone equip. with R.C.A. Victor Co. Prefer eastern or southern U.S. C-4220.

E.E., 27, 1 yr. practical experience, Westinghouse Co., testing motors, generators, transformers, steam turbines, relays, and control equipment; 3 yr. with a pwr. company, substation layouts, cost analysis, estimating, drafting, and development work. D-748.

E.E. GRAD., Univ. of Ill., single, 22. Excellent scholastic record. Experience in utility engg. and in control research and design. Good references. Available immediately. Any location. D-759.

M.E. GRAD., Stevens Inst. of Tech., 24, single, 8 yr. in elec. work for light and pwr. of all descriptions. Also communication knowledge with experience. Location, immaterial. C-9976.

**Maintenance and Operation**

E.E. GRAD., married, 28, with wide experience in industrial plant elec. construction and maintenance; ry. electrification; pwr. plant design, estimating, and supervisory construction experience with elec. contractor; cost analysis. Desires position with future. C-4428.

GRAD. ENGR., 32, married, 1 yr. telephone engg.; 5 yr. construction, operation, test and maintenance of underground transmission, and distribution cable and equip.; 3 yr. transmission and distribution engg. D-623.

COMMUNICATION ENGR. Broad theoretical experience telegraph, telephone, radio, etc., design, installation and maintenance. Many years foreign service. Available U.S. or abroad on short notice. C-8805.

E.E. GRAD., 1928, 6 yr. hydro and steam plant elec. operation and maintenance; 5 yr. office and cost accounting, expert stenographer and bookkeeping. Desires position with utility or mfg. concern in any part of U.S. or foreign. C-7796.

**Production**

INDUSTRIAL ENGR., E.E. grad., 28, married. Now employed by large mfr. of elec. equip.; 2 yr. experience test engr.; 4 yr. wage incentive installation, including job analysis, methods engg., time study, cost control, and supervising wage system operation. Excellent references. D-737.

**Research**

E.E., B.S., E.E., 28, single. Experience: Testing a-c. and d-c. machines in process of construction. G.E. Test course. Drafting, designing of elec. testing equip. Developmental work on instruments and instrument transformers. Work preferred: Development, layout, installation, maintenance of plant equip. in industrial pwr. company. Location preferred: East, Middle West. D-726.

JR. ENGR.-STATISTICIAN: B.S. in E.E. 1930, 25, single, $1\frac{1}{2}$ yr. statistical and economic research experience. Thorough tech. and business training. Speaks Spanish fluently. C-7551.

**Sales**

E.E. GRAD., 1929, 27, single, 2 yr. exceptional experience as jr. engr. with pwr. co. including commercial, engg., construction, and pwr. plant, 1 yr. experience pwr. sales and industrial engg., Desires position preferably in pwr. sales or industrial engg. Excellent references. Location, South preferred. Available at once. D-605.

SALES MGR., ENGR., 35, experienced capable sales contact man, desires connection as representative or mfr. agt. with high grade company mfg. line of high or low voltage equip. for utilities or industrial plants. B-4067.

SALES ENGR., grad. E.E., 33, married. Excellent background of sales and adv., desires connection with mfr. Location preferred, Middle West. Experience in industrial adv. in addition to engg. and selling of elec. equip. Excellent references. B-8614.

SALES ENGR., single, grad. Kansas Univ. '29. G.E. Test course including photophone, radio, industrial control, motors, transformers, and quotation work; 8 months engg. street ry.; 5 months sales engg. with large dealer in new and rebuilt elec. mchy. Now employed. D-674.

ENGR. (British), now engaged, desires correspondence with mfr. in U.S. desirous of establishing branch industries on other side. Also familiar with Canadian, Indian, and African conditions. D-699.

SALES ENGR., E.E. grad., 30, married, 1 yr. testing and engg. western utility; 2 yr. testing; $4\frac{1}{2}$ yr. design, application, and sales engg. with G.E. Desires permanent connection engg. or sales dept. with utility or mfr. Available at once. New York State or East preferred. D-696.

SALES ENGR., col. grad., 36; G.E. Test (steam and elec.) also factory and district office sales experience. For last few years employed as senior industrial engg. representative (elec.) with outstanding central station company. Would like new affiliation preferably in the East. C-5618.

SALES ENGR. OR MFRS. AGT., grad. E.E., 32, over 5 yr. utility in construction, maintenance, and design, over 3 yr. as sales engr. for elec. mfr., including about 3 yr. as jr. exec. Location, immaterial for salary position. Pittsburgh headquarters as mfrs. agt. D-745.

# Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the address as it now appears on the Institute records. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Berry, Wayne J., c/o Genl. Elec. Co., Schenectady, N. Y.
Bugg, Vernon, 736 Transportation Bldg., Washington, D. C.
Du Rieu, E. F., c/o Tate & Hays, 341 Madison Ave., N. Y. City.
Iwe, Halfdan G., 229 Ovington Ave., Bklyn., N. Y.
Miyamoto, Tatsuo C., 1330–4th St., Sacramento, Calif.
Palit, Hari-Charan, 151 Ganesh Mohal, Benares City, India.
Rogge, C. A., Consumers Pwr. Bldg., Jackson, Mich.
Scanlon, D. L., KFPW, Ft. Smith, Ark.
Schwartz, Carl, 410 Cathedral Pkwy., N. Y. City.
Thomas, Earl Mead, Intl. Genl. Elec. Co., Schenectady, N. Y.
Titland, Trygve T., 1019 Stanton Ave., Elizabeth, N. J.
Van Ness, L. G., 2105–6 Sterick Bldg., Memphis, Tenn.

# Membership

## Applications for Election

Applications have been received by the secreatry from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the assistant national secretary before May 31, 1932.

Anderson, C. J., Barber-Colman Co., Rockford, Ill.
Bailey, R. S., Kansas Gas & Elec. Co., Wichita (Applicant for reelection)
Caldwell, C. W., Univ. of South Dakota, Vermillion
Colclough, O. T., Consumers Pwr. Co., Muskegon Heights, Mich.
Cordray, R. E., Genl. Elec. Co., Phila., Pa.
Cotter, M. T., 1001 W. Clay St., Ukiah, Calif.
Dilley, M. M., Automatic Safety Signal Gate Co., Louisville, Ky.
Dumelow, L. S., 34 Church St., Alton, R. I.
Elley, A. C., Yates-American Machine Co., Beloit, Wis.
Fields, C. W., Jr., New York & Queens Elec. Lt. & Pwr. Co., Flushing, N. Y.
Gibson, N. R. (Member) Buffalo, Niagara & Eastern Pwr. Corp., Buffalo, N. Y.
Gray, T. J. (Member), Pub. Serv. Co. of Colo., Fort Collins
Guptill, C. F., United Electric Lt. & Pwr. Co., N. Y. City
Harvey, J. H. (Member), Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
Hildebrand, A. M., Lake Erie Pwr. & Lt. Co.; Lake Shore Elec. Ry. Co., Sandusky, Ohio
Horton, H. M., Okla. Gas & Elec. Co., Okla. City
Jelinek, U., 132 Smith St., Elizabeth, N. J.
Kersten, A. W., Wisconsin Tel. Co., Milwaukee
Klaus, C. E., Westinghouse Elec. & Mfg. Co., Portland, Ore.
Kolks, R. H., Union Gas & Elec. Co., Cincinnati Ohio
Leha, H., 1369 Freemont Place, Elizabeth, N. J.
Litchfield, W. L., 28 Spring St., Danbury, Conn.
Mansfield, W. A. Conduits Co., Ltd., Toronto, Ont., Can.
May, R. W., Dept. of Public Works, N. Y. City
McTwiggan, T. L., 130 Rich Ave., Mt. Vernon, N. Y.
Michel, C. B., Bell Tel. Co. of Pa., Philadelphia
Milligan, J. W. (Member), Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
Niemann, W. H., Intl. Time Recording Co., San Antonio, Tex.
Rosecky, J. J., Univ. of Wisconsin, Madison
Rote, F. J., Brooklyn (B. Y.) Edison Co., Inc.
Rowe, W. H., Genl. Elec. Co., Lynn, Mass.
Sykes, W. E., Bell Tel. Co., Toronto, Ont., Can.
Tweedle, C. E., L. S. Vallely & Co., Houston, Tex.
Webb, R. B., Southwestern Bell Tel. Co., Dallas, Tex.
Weil, C. R., Gould Storage Battery Corp., Depew, N. Y.
35 Domestic

### Foreign

Ali, S. N., H. H. Government, Patiala State, Punjab, India
Crisp, H. K., Municipalities of Bowral and Mittagong and Shire of Nattai Bowral, N. S. W., Australia
Gokli, K. N., R. Gokli & Co., Matunga, Bombay, India
Gomez, A., Chilean State Rys., Valparaiso, Chile, So. Am.
Perry, A. M., Hachbridge Elec. Construction Co., Surrey, England
5 Foreign

# Engineering Literature

## New Books
### in the Societies Library

Among the new books received at the Engineering Societies Library, New York, during March are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no reponsibility for statements made in the following outlines, information for which is taken from the preface or text of the book in question.

TABLES ANNUELLES DE CONSTANTES ET DONNÉES NUMÉRIQUES de Chimie, de Physique, de Biologie et de Technologie, v. 8, 1927–8, Pt. 1. Paris, Gauthier-Villars et Cie; N. Y., McGraw-Hill Book Co., 1931. 1101 p., 11x9 in., cloth, $10, Pt. 1.—Presenting a year by year compilation of the numerical constants and data that have appeared in the important scientific periodicals. The present part covers mechanics, heat, light, electricity, and magnetism. Titles and explanatory matter are given in English as well as in French.

ADVANCED ELECTRICAL MEASUREMENTS. By W. R. Smythe and W. C. Michels. N. Y., D. Van Nostrand Co., 1932. 240 p., illus., 9x6 in., cloth, $3.00.—Intended for training in the use of research methods and instruments and testing, and development work; a course given to senior students at the California Institute of Technology. Standard electrical measurements are included; also methods for measuring temperature, radiation, and other quantities not primarily electrical. The theory of each method is discussed, and references for further reading provided.

APPLICATIONS OF REFRIGERATION. Book J. By C. T. Baker and I.C.S. Staff. Scranton, Pa., Intl. Textbook Co., 1929. 44 p., illus., 8x5 in., cloth, $1.25.—A description of the principles and construction of the most popular types of refrigerating machines. Automatic for commercial and domestic use.

ARTIFICIAL LIGHT AND ITS APPLICATION IN THE HOME. By the com. on res. ltg. of the Illum. Engg. Soc., Mariquita Dygert, Chmn. N. Y. & Lond., McGraw-Hill Book Co., 1932. 145 p., illus., 9x6 in., cloth, $1.50.—A concise, practical book on the lighting of residences, prepared by a group of authorities and endorsed by the Illum. Engg. Soc. Primarily a text for students of home economics, but also of use to housewives in search of simple, reliable information on artificial lighting.

BOOK OF METALS. By D. Wilhelm. N. Y. & Lond., Harper & Bros., 1932. 341 p., illus., 10x7 in., cloth, $4.00.—A story of industrial metals, their history, mining, refining, alloying characteristics, and uses. Breezy and popular, but read and accuracy approved by acknowledged authorities. For needs of general information on the metals.

DIE ELEKTRISCHE FERNÜBERWACHUNG UND FERNBEDIENUNG FÜR STARKSTROMANLAGEN UND KRAFTBETRIEBE. By M. Schleicher. Berlin, J. Springer, 1932. 238 p., illus., 9x6 in., 21 rm.—Remote control and supervision of machinery and power methods are presented systematically. Calling attention to underlying principles and fields of usefulness rather than to details of instruments. Remote metering, signaling, and control are considered. Bibliography.

DYNAMICS OF ENGINE AND SHAFT. By R. E. Root. N. Y., John Wiley & Sons, 1932. 184 p., illus., 9x6 in., cloth, $3.00.—For 12 years Prof. Root has given a course at the postgraduate school, Naval Academy upon this subject, and the results of his experience appear in this brief textbook. It aims to present methods for evaluating the forces that operate in a reciprocating engine, to trace their effects in turning moment on the shaft and in bearing pressures, and to reveal their significance in relation to vibrations. The book also treats of torsional and transverse vibrations of elastic systems and discusses critical speeds.

FREILEITUNGSBAU MIT SCHLEUDERBETONMASTEN. By L. Heuser and R. Burget. München & Berlin, R. Oldenbourg, 1932. 176 p., illus., 10x7 in., paper, 10 rm.—A comprehensive account of the history and construction of the hollow concrete pole and its use for overhead electric lines. Discusses design and testing of poles, transport and erection, costs, and applications to power, telephone, and telegraph networks. Includes table of all the European lines on concrete poles.

GENL. ENGG. HANDBOOK. Edited by C. E. O'Reurke and others. N. Y., McGraw-Hill Book Co., 1932. 921 p., illus., 8x5 in., leath., $4.00.—In preparing this compendium of engineering data, attempt has been made to compress the important fundamentals of engineering into a single small volume which will supplement detailed handbooks devoted to one field. Divided into 31 sections, six devoted to subjects of interest to all engineers. The remainder treat the major branches of civil, mechanical, and electrical engineering. Each section by an expert in its field.

HANDBOOK OF BUSINESS ADMINISTRATION. W. J. Donald, ed. N. Y. & Lond., McGraw-Hill Book Co., 1931. 1753 p., illus., 7x5 in., leath., $7.00.—An encyclopediac presentation of current practise in all departments of business, prepared specialists and sponsored by the Am. Mgmt. Assn. Marketing, financial production, and office management; personnel and gen. mgmt. are discussed in all ramifications. A concise, handy summary of the policies of many business leaders.

JOBS, MACHINES, AND CAPITALISM. By A. Dahlberg. N. Y., Macmillan Co., 1932. 252 p., illus., 8x6 in., cloth, $3.00.—The author believes that capitalism as a system of economy has not had a fair trial and that under certain conditions it can secure all and more than communism, while avoiding the major difficulties and evils of the latter system. The evils of capitalism would disappear, he believes, were it forced to work under a chronic scarcity of labor rather than a chronic scarcity of job and business opportunity. A method for accomplishing it is suggested.

LEHRBUCH DER RADIOAKTIVITÄT. By G. v. Hevesy and F. Paneth. 2. Auflage. Leipzig, J. A. Barth, 1931. 287 p., illus., 9x6 in., paper, 22 rm; bound, 24 rm.—The aim of the authors of this work has been to supply a text-book concisely covering the whole field of radio-activity, in which due attention is paid both to its physical and chemical aspects; its relations to other branches of science are indicated. Revised and partly rewritten.

LUFTBEHANDLUNG IN INDUSTRIE— UND GEWERBEBETRIEBEN. By L. Silberberg. Berlin, J. Springer, 1932. 174 p., illus., 10x6 in., cloth, 18 rm.—On air conditioning; intended to provide an account of current practise for engineers and factory owners. An introduction devoted to scientific principles, the technique of air conditioning is discussed at some length. The solution of problems involved, and the apparatus used are considered, with advice on systems and operating costs.

MANUAL OF ELECTRIC ARC WELDING. By E. H. Hubert, ed. N. Y. & Lond., McGraw-Hill Book Co., 1932. 163 p., illus., 9x6 in., cloth, $2.00.—Explains the fundamentals of arc-welding processes, with practical suggestions for performing various welding operations and many uses of arc welding. Clear and full, presenting main facts. Sponsored by the welding section of the Natl. Elec. Mfrs. Assn.

MATHEMATICAL TABLES, v. 1. Circular and hyperbolic functions, exponential sine and cosine integrals, factorial (Gamma) and derived functions, integrals of probability integral. Lond., British Assn. for the Advancement of Science, 1931. 35 p. text + 72 p. tables, 11x9 in., cloth, 10s.—For over fifty years the British Assn. for the Advancement of Science has published from time to time mathematical tables in its reports. A selection of these now appears in revised and extended form in this volume. The tables are indicated by titles, most of them extend to twelve or fifteen decimals and include facilities for interpolation. Construction explained in the introduction. The page is large and open and the type clear.

MITTEILUNGEN AUS DEN FORSCHUNGSANSTALTEN GHH-KONZERN, Bd. 1, Heft 9, p. 201–24, Jan. 1932. Berlin, VDI-Verlag, illus., 12x9 in., paper, 2.70 rm.—The subjects discussed are: the considerations governing the choice between private and public electric plants, the economical use of rotary well drilling plants, the sustained tractive power of Diesel automobile engines, and the determination of the speed and acceleration of valves of high-speed internal-combustion engines.

MOTORBUS TRANSPORTATION. 4 v. By I.C.S. Staff. Scranton, Pa., Intl. Textbook Co., 1931. illus., 8x5 in., cloth, Book 1, $1.75; Book 2, $1.25; Books 3 & 4, $1.00 each.—Volumes cover the subject concisely yet comprehensively. The organization of bus companies, laws relating to them, operators, financial problems, equipment, maintenance, management, and other important topics are considered, and current practise in these matters is indicated.

NATL. ELEC. CODE HANDBOOK. By A. L. Abbott. N. Y., McGraw-Hill Book Co., 1932. 473 p., illus., 8x5 in., leath., $3.00.—This book is intended as a reference book for users of the Code and a text-book for a systematic study of it. Rules are grouped in a way to enable all applying to a given device or method to be found at once, their meaning clarified by comments, explanations, and diagrams.

PATHWAYS BACK TO PROSPERITY. By C. W. Baker. N. Y. & Lond., Funk & Wagnalls Co., 1932. 351 p., 8x6 in., cloth, $2.50.—A well-known engineer and economist analyzes the underlying causes of the economic and social difficulties of today and points out the paths to renewed prosperity. He finds chief requirement a more general distribution of wealth.

PHOTOELECTRIC PHENOMENA. By A. L. Hughes and L. A. Du Bridge. N. Y. and Lond., McGraw-Hill Co., 1932. 531 p., 9x6 in., cloth, $5.00.—This work aims to provide a concise, yet comprehensive critical survey of the whole field of photoelectric phenomena. The present status of the three major branches of photoelectricity, surface, volume, and photovoltaic effects is summarized; fundamental laws, their experimental bases, and theoretical significance are discussed, and their practical applications briefly reviewed. No formal bibliography, but ample bibliographic footnotes.

PROFITABLE PRACTISE IN INDUSTRIAL RESEARCH. Edited by M. Ross, M. Holland and W. Spraragen, prepared under the auspices of the Natl. Research Council. N. Y. & Lond., Harper & Bros., 1932, 269 p., 9x6 in., cloth, $4.00.—A symposium by the directors of some of the greatest industrial research laboratories of the country. The philosophy and practical application of industrial research, the organization of research departments, the selection of research workers, research work in foreign countries, the part played by trade associations, the government and universities, and the transference of the results of research to the factory all are discussed.

REWINDING DATA FOR D-C. ARMATURES. By G. A. Van Brunt and A. C. Roe. N. Y., McGraw-Hill Book Co., 1932. 212 p., illus., 9x6 in., cloth, $2.50.—Gives practical directions for taking and recording, in a uniform, systematic manner, the information for repairing these armatures. Also the rules governing the various types and windings, and chapters devoted to materials, insulation, banding, dipping and baking. Several chapters on "frog-leg" windings. Expanded from articles that appeared in "Maintenance Engineering."

STANDARD WIRING FOR ELEC. LT. AND PR. By H. C. Cushing, Jr., 38 ed. N. Y., H. C. Wushing, Jr., 1932. 488 p., illus., 7x4 in., leather, $3.00.—A new edition of a well-known guide like its predecessors sets forth clearly and fully the essential requirements for safe and efficient wiring and construction and the latest engineering practise. Complies with Natl. Electric Code.

COLOUR SCIENCE, Part 1. By W. Ostwald. Authorized translation with introduction and notes by J. S. Taylor. The April issue of ELECTRICAL ENGINEERING gave the address of the publishers, Winsor & Newton, Ltd., as London. They are of London and New York.

**Engineering Societies Library**

29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a cooperative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

# Industrial Notes

**Multiple "V" Belt Patent Suit Settled.**—The Allis-Chalmers Manufacturing Company announces that the suit between it and the Dayton Rubber Manufacturing Company, of Dayton, Ohio, in the United States District Court at Cincinnati, involving patent infringement of Allis-Chalmers Geist patent No. 1,662,511 pertaining to multiple "V" belt drives has been settled out of court. The Dayton Rubber Manufacturing Company takes a license under the Geist patent and the Allis-Chalmers Manufacturing Company has the right to operate under Short patent No. 1,538,303, if it so desires.

**Corning Glass Appoints Insulator Representatives.**—The following appointments have been announced by the Corning Glass Works, Corning, N. Y., of representatives for the sale of "Pyrex" power insulators: J. E. Redmond of Phoenix, Arizona, for Arizona, New Mexico, and the El Paso district of Texas; J. Q. Lalor, Denver—Colorado and Wyoming; L. B. Graves, Minneapolis—North and South Dakota, Wisconsin, and Minnesota; A. J. Heisel, New Orleans—Mississippi and Louisiana; Wise & Braisted, Detroit—Michigan.

**Norma-Hoffmann Moves New York Sales Office.**—Announcement has been made by the Norma-Hoffmann Bearings Corporation, manufacturers of "Precision" ball, roller, and thrust bearings, that its New York sales office has been moved from the Grand Central Terminal to new and larger quarters in the Commerce Building, 155 East 44th Street. A full staff of sales engineers with increased facilities will continue to serve the Eastern territory.

**New Double Row Ball Bearing.**—The Federal Bearings Company, Inc., Poughkeepsie, N. Y., announces the introduction of a series of double row, self-aligning radial ball bearings, available in all popular sizes. One of the important features of this series is a separate ball spacer or retainer for each row of balls. This is particularly advantageous when bearings are used under conditions where the self-aligning feature is frequently brought into use. This flexible retainer absorbs much of the severe strain to which retainers in self-aligning bearings are usually subject.

**A New Electrographitic Brush.**—The National Carbon Company, Inc., Carbon Sales Division, Cleveland, announces a new electrographitic brush known as National Pyramid Grade No. 234. A unique characteristic is the non-resilient structure, enabling the brush to maintain exceptionally firm contact on commutators of high peripheral speed. It is claimed that excellent commutation, low friction and high carrying capacity combine with the smooth riding properties of this new grade to minimize brush wear and commutator maintenance. The new brush is designed especially for heavy duty, d-c. generating and substation equipment.

**Surge Diverters for Distribution Transformers.**—Coordination of the transformer insulation so that the bushing will flash over before the windings fail, gives "surge-proof" characteristics to a transformer, but naturally, when the bushing flashes over, a power arc may follow of sufficient magnitude to blow the primary fuses, according to the Allis-Chalmers Mfg. Company, Milwaukee, Wis., which announces surge diverters for application with their distribution transformers to eliminate this effect. The surge diverter has been designed to function in less than 50 microseconds so that it can be connected between the primary fuses and the transformer. This rapid action does not give time for the fuse to operate so that fuse blowings are minimized. Surge diverters may be installed outside or inside the transformer case. The flexibility in mounting makes it possible to connect the diverter either to separate ground connections or to secondary neutrals as desired.

# Trade Literature

**Instrument Transformers.**—Catalog GEA 601D, 52 pp. Describes standard lines of GEA switchboard and portable transformers; includes dimensions. General Electric Company, Schenectady, N. Y.

**Groundometers.**—Bulletin 120C, 8 pp. Describes various types of ground testing instruments, each designed for a particular class of testing. Borden Electric Company, 480 Broad Street, Newark, N. J.

**Distribution Transformers.**—Bulletin 8248-A. Describes a new distribution transformer which will not be injured by lightning surges entering either the primary or secondary windings. Westinghouse Electric & Mfg. Company, Sharon, Pa.

**Magnetic Across-the-Line Switches.**—Bulletin GEA 1568. A complete treatment of G-E control equipments of this type for every service in all sizes up to 1200 hp.; explosion-proof, oil-immersed, etc. General Electric Co., Schenectady, N. Y.

**Lightning Arresters.**—Bulletin 1, 8 pp., the first of a series describing crystal valve lightning arresters for high and low voltage transmission and distribution circuits, and for telephone and telegraph lines. Electric Service Supplies Co., 17th and Cambria Streets, Philadelphia, Pa.

**Cements and Compounds.**—Bulletin 32, 16 pp. Describes a line of cements and industrial compounds for acid-proofing, surface coating, impregnating, oil resisting, electric insulation, repairing, etc. Technica Products Company, Pittsburgh (Sharpsburg Station), Pa.

**Insulating Oil Purifiers.**—Bulletin, 20 pp. Describes the "Buckeye" hydro-volifier for purifying insulating oils. Analyses of insulating oils as contaminated by various uses and their purification by the vacuum treatment with the hydro-volifier are outlined. The Buckeye Laboratories, Inc., 510 West Ely Street, Alliance, Ohio.

**Radio Transformer.**—Bulletins 121A, 122 and 123. Describe Acme step down transformers, replacement transformers, and power transformers, respectively. These products are made principally in large quantity production for radio and allied manufacturers. The Acme Electric & Mfg. Company, 1444 Hamilton Avenue, Cleveland, Ohio.

**Small Rotary Converters.**—Bulletin and price list, 8 pp. Describes new, improved "Martin" interpole, alternating current to direct current, ball bearing rotary converters, with panels and resistances, for motion picture and general theatre use. Northwestern Electric Co., 418 South Haynes Avenue, Chicago, Ill.

**A-C. Rectifier Power Packs.** Bulletin, 4 pp. Describes "Rectopacs"—complete d-c. power packs for industrial applications to operate from a-c. lines. These B-L rectifier assemblies are used in the operation of signal systems, magnets, relays, control equipment, low voltage motors, battery charging, etc. B-L Electric Mfg. Co., 19th & Washington Ave., St. Louis, Mo.

**Power Factor Correction.**—Bulletin. Describes how power factor may be corrected through the use of static condensers in convenient unit form, assembled and mounted to meet any requirements. The bulletin contains an ingenious scale whereby the condenser capacity required for any given power factor correction may be instantly determined. Dubilier Condenser Corporation, 4377 Bronx Blvd., New York.

**Testing Machines.**—Catalog 50H, 116 pp. Describes Olsen testing and balancing machines and instruments. Such equipment is made for numerous purposes including tests for endurance, fatigue, hardness, flexibility, etc., of materials. Static and dynamic balancing machines are used by manufacturers of motors and turbines for determining armature and rotor balance. Tinius Olsen Testing Machine Co., 500 North 12th Street, Philadelphia, Pa.

**Insulators.**—Catalog 32, 320 pp. This volume is described as a handbook of reliable information for those interested in modern methods of high voltage transmission. The catalog includes illustrations, cross sections and specifications of Locke insulators. Methods of manufacture are depicted, and the history of the Locke grading shield is outlined. Included are the A.I.E.E. and NEMA Standards for insulator tests; also wire and cable tables. Locke Insulator Corporation, So. Charles & Cromwell Streets, Baltimore, Md.

Annual Technical Committee Reports . . . . . 433

NATIONAL and District prizes awarded by the A.I.E.E. for technical papers presented during 1931 were announced recently. *p. 418*

THE telephone handset, although "taken for granted" as are many of our modern conveniences, required long and painstaking research to make it a practical reality. *p. 380–383*

H. H. HENLINE, for more than five years assistant national secretary of the A.I.E.E., on June 1 became the Institute's managing executive by unanimous action of the board of directors. *p. 415–416*

POST-WAR deflation combined with a slackening of opportunity for profitable investment are held responsible for present economic conditions. This is one of the theories advanced in a progress report of a comprehensive study undertaken by a special committee of the American Engineering Council. *p. 373–379*

ALL ABOARD for Cleveland and the Institute's annual summer convention to be held in the "forest city" June 20–24! There will be no registration fee; special entertainment and sports events are scheduled; interesting inspection trips are planned; all technical sessions are to be held in the mornings. *p. 414*. Abstracts of papers to be presented are published in this issue. *p. 405–413*

WHEN planning your summer vacation don't overlook an excellent opportunity to combine business with pleasure by attending the 1932 A.I.E.E. Pacific Coast convention to be held August 30 to September 2 in Vancouver, B.C. Popularly known as the "evergreen playground" this young and progressive city and the surrounding country possess unusual recreational attractions. *p. 414*

A POWER STATION in which the development over a ten-year period had been such that the latest unit has practically five times the capacity of the first, offers a distinct challenge to the engineer; such is the history of the Waukegan generating station of the Public Service Company of Northern Illinois. Its latest installation includes a 115,000-kw. single-shaft steam-electric generator, and the first 132-kv. metal-clad switchgear ever built. *p. 391–400*

# Keep Abreast of Your Profession

By E. B. MEYER FELLOW A.I.E.E. Chairman A.I.E.E. Publication Committee

G. ROSS HENNINGER MEMBER A.I.E.E. Associate Editor, A.I.E.E.

**Can you attend six conventions a year? Can you digest 150 or more technical papers each twelve months? Can you personally meet satisfactorily the demands imposed by the continuing rapid evolution in the art of electrical engineering and its successful application? This article may reveal to you unexpectedly available facilities.**

IN A SENSE this is an anniversary month, a seemingly reasonable excuse for a bit of stocktaking. Just two years ago, May 5, 1930, to be exact, the A.I.E.E. publication committee concluded more than two years of intensive investigation, and brought forth its memorable report on "proposed changes in policy of A.I.E.E. publications." Subsequent adoption by the board of directors, June 23, 1930, converted the committee's recommendations into Institute policy, one of the tangible results of which was ELECTRICAL ENGINEERING as a New Year's greeting for 1931.

## BASIC PLAN

To provide a basis of comparison, a few of the more important points involved in the publication committee's 1930 recommendations will be outlined briefly here.

Recognizing that the Institute to keep growing must be alive to the changing requirements of its members; recognizing that the Institute's activities and publications to serve adequately must be alive to changing conditions; and recognizing that the monthly publication constitutes the main channel through which Institute members may keep informed conveniently and effectively as to current technical and professional developments and the Institute's participation therein, the committee selected the monthly publication as representing the logical field in which to pioneer the development of increased and more effective publication service to members. Out of the hundreds of letters exchanged in the publication committee's nationwide survey, the general features of a basic policy took the following tangible form:

1. Organize the editorial content of the monthly publication to serve better the needs and desires of the average individual member of the Institute.
2. Include, at least in the form of comprehensive interpretative abstracts, every paper formally presented before Institute conventions and District meetings.
3. Give special attention to the more timely papers of wider general interest.
4. Distribute to the entire membership the annual reports of the Institute's technical committees.
5. Solicit and convey to the membership special articles on timely scientific, economic, and other subjects of interest and importance to electrical engineers.
6. Reflect important contemporary developments in allied fields, and
7. Reflect more adequately the Institute's important activities, including its Section and Branch work.

In short, the assignment called for the Institute's monthly publication to carry conveniently and directly to every Fellow, Member, Associate, and Enrolled Student of the Institute a comprehensive and illuminating month-by-month cross-section of professional activities and electrotechnical developments in many related fields of endeavor.

## WHAT HAS BEEN DONE?

Comments from members indicate that for sixteen months ELECTRICAL ENGINEERING has been doing this job with increasing effectiveness. From January 1931 to and including May 1932, ELECTRICAL ENGINEERING has brought you comprehensive interpretive abstracts of 128 Institute papers, 179 articles giving you either the entire or the essential substance of an equal number of Institute papers, and 84 articles of a special character selected for their timeliness and importance and to give a better balance to the published material. ELECTRICAL ENGINEERING in these few months has reported the activities at four national conventions and six District meetings, to say nothing of almost innumerable other events of significance and importance. For those who might enjoy some interesting statistical information, the accompanying tabulation is presented.

## A REAL JOB

ELECTRICAL ENGINEERING'S relentlessly prosecuted endeavor is to serve to the greatest possible advantage the maximum proportion of the Institute's entire membership. The magnitude and complexity of this endeavor perhaps may be made more understandable by an analysis revealing the tremendously wide spread of activities in which Institute members are engaged. On the basis of the Institute's enrolment as recorded in the 1930 Year Book—17,633 Members and 2,446 Enrolled Students totaling 20,079—approximately 16 per cent are in design and manufacturing, 9 per cent in communication, 6 per cent in industry, 5 per cent in construction, 18 per cent in electric power supply, 3 per cent in railways, 6 per cent in research and education, 1 per cent in radio, 12 per cent are students, 16 per cent unclassified, and 8 per cent are in foreign fields.

For any one publication to attempt to serve exhaustively all the interests of such a widely diversified group obviously would result in a ponderous volume; for a publication to devote itself exhaustively to the interests of any one group would be to disregard the interests of the others. One of the prime functions of the Institute is to serve as a coördinating medium embracing these closely related groups of diverse interest. It is the function of Electrical Engineering to effect an interchange of information by means of which individual members may reduce the inevitable personal hazard of ever-narrowing specialization in professional practise.

### A Strong Policy

Electrical Engineering is based upon a liberal, constructive policy, and is designed with sufficient flexibility to meet effectively the constantly changing requirements of the Institute's membership. Into its policy are inculcated a bit of reticence and reserve to preserve its stability, sufficient initiative and daring to prevent its stagnation, a reverence for tradition in so far as that tradition is soundly founded and still serving a definitely useful purpose, and above all, a driving motivation to serve honestly, effectually, and unselfishly; it is edited for Institute members by a staff of Institute members whose prior industrial service has provided a solid background of experience.

**Contents of ELECTRICAL ENGINEERING for the 12 Issues of 1931**

| | Classification of Material | No. Pages |
|---|---|---|
| 1. | 137 technical articles giving the essential substance of 150 A.I.E.E. papers (also 29 interpretive abstracts of Pacific Coast and Kansas City papers) | 360 |
| 2. | Annual reports of 17 Institute technical committees | 90 |
| 3. | 33 special articles including non-technical contributions | 85 |
| 4. | 27 special articles originating in or coming through Institute channels | 69 |
| 5. | News reports covering three national conventions, three District meetings, and other Institute activities | 85 |
| 6. | Brief reports of 492 Section and 1,112 Branch meetings | 57 |
| 7. | 1,231 selected references to current periodical electrical literature | 48 |
| 8. | 311 personal items pertaining to activities of Institute members | 33 |
| 9. | 798 items from Engineering Societies Employment Service | 27 |
| 10. | Reference listings of A.I.E.E. official and committee personnel (published in full in January and September, in part in February and March) | 21 |
| 11. | News of activities of other engineering societies | 18 |
| 12. | Postings of 1,073 members for election or transfer | 14 |
| 13. | Notices of 165 new books of interest to electrical engineers, as received by the Engineering Societies Library | 11 |
| 14. | 13 "Letters to the Editor" (a new column started late in the year) | 6 |
| 15. | Miscellaneous material | 74 |
| | Total pages editorial content | 998 |

### Interpretive Abstracts

One experiment has concerned the manner and form of publishing abstracts of formal Institute papers. From the earlier policy of publishing miscellaneous groups of abstracts month by month, the plan has evolved to the present practise of publishing, directly in conjunction with the meeting at which they are presented, a related group of carefully prepared interpretive abstracts. This present plan accomplishes a wide and time distribution of essential facts covered in current papers, and clears the way for a full and independent treatment of those subjects of greatest timely importance and widest general interest.

Another experiment, also initiated through the 1930 report of the publication committee, seems definitely to have come to a close. In fourteen successive issues some 1,458 "selected items" from the Engineering Index's current periodical reference service were republished. Since the complete reference service is rather widely available through the libraries of the country and through direct subscription, and since, at best, only limited space was available in Electrical Engineering, this publication experiment was concluded in the February 1932 issue.

### More for Your Money

To improve its production and distribution, Electrical Engineering recently completed an extensive and critically searching inquiry into these phases of its operations. As a result, it has transferred its production activities to a new and larger plant removed from New York's congested metropolitan area and devoted primarily to scientific and technical periodicals. Benefiting from its new and improved facilities, Electrical Engineering now brings to you in its usual 72 pages of editorial content an amount of material that previously would have required 79 pages, and should reach you several days earlier than heretofore. New paper of higher quality and softer finish now protects your eyes from the fatigue of reflected light; greater opacity improves readability. Of importance and significance in connection with these improvements is the fact that, at the same time, production costs have been reduced materially.

### Open Forum

In its present experimental "Letters to the Editor" columns, Electrical Engineering offers to the members of the Institute a readily available channel for the frank and informal discussion of almost any topic of timely interest. These columns are gaining in apparent popularity; certainly they merit attention and widespread use.

### Your Journal!

The monthly publication Electrical Engineering is well understood to be one of the Institute's most important services to its every member; therefore its publication committee and staff are determined to pursue relentlessly every opportunity to make this service more widely useful and more definitely valuable. It will continue to pioneer the way in the direction of greater and more effective publication service to Institute members; it will continue to prosecute experiments into unknown portions of the field represented by membership desires; it will make mistakes, undoubtedly, but it will not falter in its *effort* to serve. Its ambition is to be neither the first to absorb every new idea, nor the last to abandon an old one that has become out-moded.

Electrical Engineering is your publication, produced aggressively to the composite specifications of the Institute's membership. Use it! Contribute your ideas for its improvement that it may continue to serve you, and better.

## The Relation of

# Consumption, Production, Distribution

### A Progress Report of American Engineering Council*

**Council has undertaken a comprehensive study of a far-reaching problem which in one way or another undoubtedly affects every member of the Institute. In recognition of the highly controversial nature of this whole general subject, essentially the full text of a progress report is presented in ELECTRICAL ENGINEERING, without comment, but with an open invitation for comments, criticisms, and suggestions. ——The Editors.**

AMERICAN Engineering Council in January 1931 authorized the appointment of a special committee to study the relation between consumption, production, and distribution. When appointed, the committee was assigned the task of studying the following suggested points of attack relating to the balancing of economic forces:

1. Maintaining or increasing the consumption of goods and services
2. Balancing of plant, machinery, and processes against production demands
3. Balancing of distribution agencies against consumer requirements
4. Balancing of man power against production and distribution demands
5. Controlling of money and credit to satisfy the needs of government, business, and individuals
6. Encouragement of research activity to increase human well-being through development and progress in industry and business
7. Balancing of public works against public needs.

To this list has been added one other, which is involved in all of the others, and is of such importance as to demand particular study:

8. Balancing of agricultural supply with effective demands.

Economic balance obviously can be attained at widely different levels of the general standard of living. However:

> The committee has interpreted its commission as being the selection and recommendation of such governmental, financial and business policies as will maintain in the United States a standard of living that is high, broadly distributed and free from severe fluctuations.

Being acquainted with the control of the forces and the utilization of the materials of nature for the benefit of man through the instrumentality of modern technology, and realizing that this method is applicable likewise to the control of many economic forces:

> The committee believes that the objective stated is physically possible for the whole of western civilization.

This statement is contrary to the assumption revealed in much present day speaking, writing, and thinking on economic matters.

Furthermore, in view of the natural resources, the technological development, the limited degree of dependence upon foreign countries for raw materials, and other important factors which characterize the United States:

> The committee believes that in a very large degree the desired economic readjustment can be realized in the United States, even though it may be impracticable to accomplish such a purpose throughout the western world.

This thought is contrary to a large body of opinion which questions the ability of the United States to rise above world conditions.

In studying the problems outlined, the committee has not confined itself to engineering viewpoints, nor to engineering solutions. Observed similarities between engineering and economic principles are accepted as evidence of a vital relationship between the two sciences.

### PRESENT SITUATION INADEQUATELY EXPLAINED

In an effort to establish a working hypothesis, the committee endeavored to find adequate explanations for the present economic situation. As a result the committee finds the following popular explanations to be questionable and/or inadequate:

Technological unemployment
Wasteful manufacture and distribution
General over-production
Speculation
Installment buying
Breakdown of international trade and credit

**Technological unemployment** is the term commonly applied to the displacing of labor by the improvement of machinery, processes, and organization. Some have assumed that a catastrophic cumulation of unbalance from this cause is responsible for the present recession in business, but no evidence is available to prove this, and there is definite evidence to the contrary. This statement is not intended to minimize the seriousness of the problems which do arise from technological advance. At times the effect of progress *does* fall with crushing force upon individuals, business firms, entire industries, and whole communities. However, it must be remembered that technological developments

Co., Springfield, Vt.; L. P. Alford, vice-pres. Ronald Press Co., New York, N. Y.; F. J. Chesterman, vice-pres. & genl. mgr. The Bell Tel. Co. of Pa., Pittsburgh, Pa.; Dexter S. Kimball, dean, col. of engg., Cornell University, Ithaca, N. Y.; L. W. Wallace, exec. secy. A.E.C., Washington, D. C.

**"There are millions of families whose power to consume is lowered by faulty economic conditions. In the opening of the dormant markets they represent lies the greatest hope of American industry."**

have been going on for centuries; also that the normal method of adjusting the volume of production to a general increase in production efficiency has been a progressive shortening of working hours.

**Wasteful manufacture and distribution,** while of serious proportions, cannot be assigned as the primary cause of the existing unbalanced economic condition, and there is no element in its elimination that could be used for direct control of the business cycle. Doubtlessly distribution inefficiency has mitigated the severity of the problem of technological unemployment. Elimination of waste in both manufacture and distribution should be aggressively pursued because of its direct influence upon raising the standard of living and increasing leisure.

**General overproduction** is a commonly assigned primary cause for the business depression. In this point of view the committee cannot concur, although there may have been overproduction in specific industries. Individual readjustments required often are violent and even destructive, but their necessity never has been absent in good or in bad times. There is no evidence that their effects have been cumulative at this time. In view of the large increase in consumption physically possible in this country, the probability of having approached a condition of *general* overproduction is indeed remote. The real difficulty is due to the lack of a proper balance between production, purchasing power, and consumption; not to overproduction.

**"The depression which began in 1929 seems to be the recession phase of a typical business cycle occurring coincidently with a typical post-war deflation, and aggravated by a unique agricultural distress and a slackening of the opportunities for investment at a profit. This is a sound statement of the cause of the present depression because it comprehends a large area of observed phenomena."**

**The inordinate speculation** which preceded the collapse of the boom in 1929 undoubtedly was an aggravating element in the economic situation. This phenomenon and its opposite, the unreasoning panic which followed, are important psychological factors, but that they are primary causes of the business depression is doubtful. The time honored assumption that the open market is a steadying influence on prices evidently is a myth, at least in so far as the security market is concerned during periods of expansion. If the open market is to justify its existence upon the grounds that it has a steadying influence on prices, it must accomplish internal reform to bring its performance in line with this assumed purpose. Investment bankers and the speculating public both have definite responsibilities in the matter.

**Installment buying.** The wide extension of consumer credit masked the failure of purchasing power
to keep in step with production, a primary factor in
oom which ended in 1929. In the situation
reated, the normal effect of slackening de-
as delayed and the unstable balance pro-
Recovery has been hindered by the necessity for applying new earnings to the payment of goods already in use, instead of using them to move goods of current manufacture. There are, nevertheless, unrealized possibilities of usefulness in the extension of consumer credit, provided it is done in an appropriate degree at the proper time of the business cycle.

**Breakdown of international trade and credit.** No doubt the demoralized economic condition in Europe resulting from the World War has had a pronounced influence upon the economic condition of the United States. This is a serious situation. There is a growing belief that the financial and industrial operations of this country have been tied to foreign operations too closely and in too complicated a manner. Also it is believed that this situation has not been of any lasting benefit to either this or other countries. However, the breakdown need not be an insuperable barrier to recovery in this country in view of our wealth, natural resources, technical ability, and the small degree of necessary dependence on foreign commerce.

## APPARENT CAUSES OF PRESENT DEPRESSION

**The typical business cycle** is characterized by a failure of purchasing power to keep in balance with production. A classical economic theory asserts that purchasing power normally keeps in balance with production, being in its nature complementary thereto and consequent upon it. The theory holds under an ideal condition where business enterprise is neither expanding nor contracting, but is regularly paying out all it receives—provided all individuals, governments, and the like, do the same thing.

That this is not the normal course of business, because both individuals and business enterprises find necessary the saving of funds for future use, is the contention of two well-known authorities, Foster and Catchings, in their books "Money" and "Profits," and their numerous magazine articles. For a time at least, this act of saving withdraws funds from purchasing power, and thus makes it impossible for society as a whole to buy all the goods produced. This is their celebrated "paradox of thrift." The authors recognize the fact that money and credit are elastic quantities. Under some conditions they would expand them to make up for the amount withdrawn for savings.

A well-known English economist, J. Maynard Keynes, in his voluminous, brilliant, and difficult book "Money," resolves the paradox. He shows that the normal way in which savings are returned to purchasing power is through

**"Keynes says in effect that when the rate of investment exceeds the rate of savings, business improves and prices rise; when the rate of savings exceeds the rate of investment, business recedes and prices fall. This statement would have to be modified somewhat to apply to American conditions."**

the act of investment. By investment is meant new investment. Purchasing power is increased, and hence the tendency to maintain a balance between production and purchasing power is established, *if* the savings or moneys are used in investments, in new buildings, factories, homes, utilities, and other new wealth-producing activities.

As an example, it is probable that the general purchasing power of the country was maintained during the comparatively prosperous years from 1922 to 1926 by the rapid flow of millions of dollars of savings into the expanding automobile and other industries. Savings were not held out of purchasing power to any appreciable extent during that period, and thus purchasing power kept step with production.

According to another Englishman, J. L. Hobson (see especially his book "Rationalization and Unemployment") when too small an amount of the disbursement of wealth goes to those who earn wages and small salaries and too large an amount is paid those who earn large salaries and receive dividends, there is likely to accrue savings which cannot be invested profitably. In such a case the rate of savings exceeds the rate of investment and hence a business decline is initiated.

This general theory basically looks upon uninvested savings, of which there are hundreds of millions idle in the banks of the United States, as equivalent to unbought or at least unpaid-for goods. On the basis of this general theory, any increase in disbursements to the lower-paid classes is likely to broaden the market for goods. This is the American theory that good business requires high wages, a principle that the crash of 1929 reemphasized rather than disproved. However, it cannot be assumed that all money paid to American labor will go immediately into purchasing power because the aggregate volume of the savings of American workers is large.

Another important point is that the distribution of profits not supported by actual increased purchasing power gives an illusion of permanent prosperity. As a consequence, stocks rise, money flows into the stock market in preference to seeking lower returns from investment, and an uncontrolled and inevitably disastrous boom is on.

**"The grim processes of normal recovery from a depression have been described as consisting of the gradual exhaustion of uninvested savings, the writing off of bad debts, and the borrowing of money on life insurance to sustain existence."**

The grim processes of normal recovery from a depression were described by Virgil Jordan ("Economic Aspects of Stabilization," read before the American Society of Mechanical Engineers on Dec. 2, 1931) as consisting of the gradual exhaustion of uninvested savings, the writing off of bad debts, and the borrowing of money on life insurance to sustain existence. Other large scale operations of the same character and effect take place. When these painful processes of readjustment have proceeded so far that the purchasing power of the market exceeds current production and a lack of goods is indubitable, recovery commences.

Such appears to be, in its simplest terms, the nature of the typical business cycle, which in part is responsible for the current economic distress.

**A post-war Deflation** of "secular" or long term duration is the second element in the present business depression. Not the least of the miseries and injustices of war is the fact that for financing such a struggle no means have been discovered that do not involve inflation and the arbitrary and unsound expansion of the amount of money in use. All of this is reflected in a rise in the general price level and an immense stimulation of business. After a war ends, inflation normally is followed by a compensating deflation which may be sharp or gradual, controlled or uncontrolled. The United States now is experiencing the effects of the World War deflation.

**"Two similar depressions occurring in this country from 1820 to 1850 and from 1870 to 1895 were alleviated by the expansion of our western frontiers, new inventions, and the discovery of important new gold fields. Mining engineers now report that gold production is on the decline and that new strikes are unlikely."**

Deflations of the same type have occurred twice before in this country. From 1820 to 1850 there was a long-continued decline in the price level, characterized by bank failures, severe financial distress, three or four cycles of depressions, and political unrest. The discovery of gold in California in 1849 started a gold inflation, which is claimed to have started a period of recovery which lasted until the Civil War.

The second similar decline followed the mid-century wars of Europe and the United States and lasted roughly from 1870 to 1895. This period also was characterized in the United States by labor troubles, agricultural and political unrest, "greenback" difficulties, and a general retardation of business. It was in part alleviated in this country by the expansion of the western frontiers, by the development of natural resources, and by new inventions. This period was terminated by the discovery of gold in Australia, Alaska, and South Africa and the invention of the cyanide process of gold extraction.

The world now is experiencing a secular price decline arising from similar causes. In the two previous periods mentioned, the declines were arrested by new gold discoveries. The seriousness of the present situation is deepened by the fact that mining engineers feel very doubtful of any new large scale additions to the gold supply which would start a typical gold inflation; meanwhile the old mine workings are becoming less productive. The prospect is serious. Society does not prosper under a long continued deflation.

**The agricultural crisis** is typical of a post-war deflation, but in the United States agriculture is now burdened with new ills, particularly with regard to the great staples, wheat and cotton. Wheat is feeling not only the impact of the expansion of new territories, in Canada and Russia, but also that of new varieties and processes. A similar extension of areas applies to cotton raising. This increase in production has met a decrease in demand brought about by the introduction of rayon and changes of fashion in women's apparel.

This is commonplace process, but nonetheless distressful. It is one of the elements responsible for the present economic situation in this country.

**Reduced investment opportunities** conceivably may result from the apparent fact that the initial task of equipping a mechanized society seems to be past the stage of rapid growth. Is it not possible that this country is sufficiently equipped with railways, steamships, factories, and mines to meet all of its reasonable needs for some years to come? There is of course much work to be done and many improvements to be made, but is it unlikely that the past rate of acceleration of investment in mechanical equipment can continue indefinitely.

It is easy to become unduly and prematurely alarmed in this matter, but such a possibility is in the minds of many engineers. If the opportunities for new investment should decrease appreciably, prosperity on the Keynes formula would become more difficult. However, a countervailing factor is that one of the results would be a permanent lowering of the interest rate, which in turn would broaden the field for profitable investment.

> **"Remedial activities must be of such a nature that they do not require a beyond-human knowledge nor a beyond-human skill in planning, to become measurably effective. Also, they must take human nature as it is found, employing its forces and desires and giving direction instead of applying compulsion. These considerations seem to rule out most of the five-year, ten-year, and twenty-year plans which have been presented recently."**

## Suggested Lines of Action

The foregoing analysis seems to cover the nature of the outstanding elements of the present situation. As already stated, the opinions expressed are not fixedly held; but are subject to review and change. It was for the purpose of suggesting effective action that this investigation of causes was undertaken. The present economic situation is complex, and its correction may be expected to be equally complex. There is no single action which will be effective over the entire area of the mal-adjustment. Such simplification as is possible will result from keeping clearly in mind the ultimate objective: *a standard of living for the United States that is high, broadly distributed, and free from severe fluctuations.*

If one could take a position sufficiently far above the surface of the earth and were possessed of sufficient keenness of vision to see from that point what is going on in the United States as a whole, he would observe rivulets of materials leading from farm, forest, mine, and ocean gathering into broad streams in their flow toward industrial establishments. Thence he would see the finished goods, flowing in smaller streams to wholesalers, then in still smaller streams to retailers, and finally, as subdivided particles, reaching ultimate consumers. If it were visible, there would be a similar, but reverse, flow of money and credit in its various forms. The extent, variety, and complexity of these operations are beyond human comprehension or calculation.

The guiding principle which now preserves order in this complicated situation is the profit motive, although it has become fashionable to argue that this force tends to become ineffective and soon may be discarded. The real function of profit goes deeper than motive; in our economy it is a fundamental requirement for continued existence, and never is long neglected without vital peril. It is the ruling condition which, when effectively met, permits the superposition of many other less impersonal motives. Its useful function is in providing a firm foundation for structures more spiritual.

**Remedial activities.** Two recent attempts have been made to bring this incomprehensible mass of economic transactions under control. The first was made by the U. S. War Industries Board during the World War. This task was simplified by the fact that there was but one customer, the United States; one objective, the winning of the war; unlimited resources, that is, the artificial extending of credit which goes with war inflation. The mechanism which served the earlier occasion will not serve this one. The other attempt at complete economic planning is that going on in Russia. This effort also has been simplified. It is based upon an allegedly temporary low standard of living.

The American people have established a going mechanism of money, credit, labor, and services which operates to direct the flow of that complexity of goods which the "aerial observer" saw. Right now, the mechanism is not operating properly. However, in view of the complexity of the processes and the degree of success with which it has operated, the decision must surely be to study its deficiencies, improve its organization, and lubricate its movements, rather than to discard it forthwith. This being the necessary and logical decision, it would be wise to start the study by looking first at governmental and general financial policies which affect large operations and large sums of money rather than by attempting to develop means for arbitrarily controlling the flow of separate commodities. In fact, the immediate problem is to answer the question: How can the rate of savings and the rate of investments be balanced?

Taxation may be used to secure the desired balance. By increasing taxes during one phase of the business cycle, excess savings may be decreased; by floating government bonds at another phase an opportunity may be provided for investing savings. One means by which this can be accomplished is by establishing the principle of long-term governmental budgeting.

**Long-term budgeting** is one of the new mechanisms of management that has resulted from a union of engineering and financial principles, and one recognized as essential to first class business management. For the government to attempt to balance its income and expenditure in each fiscal year is not in accordance with the principles of good management. The government should recognize that in the course of a business cycle there is a time to tax and a time to relieve taxation, a time to borrow and a time to repay, a time to expand money and a time to contract it, and a time to extend operations for public works and a time to contract them.

It would appear that if, when employment has reached a certain low point, a policy were followed of borrowing for extending public works, this action would have a quick remedial effect on the business situation. By drawing them into government activities, such governmental borrowing would serve to reduce the accumulation of savings seeking investment.

The time for taxation is when business is good and profits are being made. Taxation then, if taken from profits, has the effect of reducing the amount of funds seeking investment and flowing into speculative channels. The concurrent repayment of the sums borrowed in the earlier period of the cycle tends on the whole to contract currency and thus acts as a brake on that upward movement of prices that is one of the factors building up the speculative structure of a boom.

Furthermore, it does not appear desirable to lay aside reserves in prosperous times to spend on public works in dull times. Such an accumulation of funds would be embarrassing to the necessary balance between savings and investment. In large scale governmental operations it is preferable, contrary to the accepted principles of financial morality, to borrow, spend, and repay rather than to save and then spend.

To recapitulate, borrowing, public works, taxation and retirement of borrowing applied at such times, in such degrees, and in such ways as may be found by experience to be useful, will have remedial effects on the business cycle itself. Thus dangerous accumulations of idle funds (implying unsold goods) will be put to work, credit will be extended by the borrowing operations thus tending to raise prices at a time when they are otherwise in danger of a disastrous lowering, and work will be furnished; all three at a time when they are most needed. Also, the reduction of public works, increased taxation, and the payment of loans will release men required for extending industry, prevent dangerous accumulations of money which can find no profitable use and, at a time when most needed, will restrain an hysterical rise in the price level, with all the train of disasters which follow therefrom.

These policies are not capable of immediate application, hence cannot be used in the present situation. The period of borrowing on most favorable terms has passed, the needed governmental reorganizations of public works control has not been effected, and the study needed to coordinate the program has not been given. The possibilities outlined will not become fully available except as they are worked out in preparation for the next turn of the business cycle.

**Non-competitive public works** are contemplated. If the government simply does work that private institutions or individuals otherwise would do, no new avenues for expenditure or investment are opened. *New* avenues are required if there is to be a better balance between the rate of saving and the rate of investment.

Furthermore, state governments, counties, and municipalities also must so adjust their taxation and borrowing programs as to draw their required finances from savings seeking investment, rather than from such sources as will place a burden on the operations of buying, selling, and manufacturing. This points to a general expansion of the income tax policy, both individual and corporate, with perhaps a new emphasis on earned *versus* unearned income as against property tax, sales tax, and other similar policies. Some of these latter taxes, such as that on gasoline sales, are useful and easily collected, and their elimination is not urged. However, they offer no creative possibilities such as appear in the income tax.

**Centralized national public works control,** for which American Engineering Council has been working for more than a decade, is necessary for carrying out the suggested program; likewise for the states, counties, and municipalities. While the suggested program may appear to require a larger amount of public works, borrowing, and taxation, than customary, this is not necessarily true. It is possible that no greater total expenditures will be required over the course of a single business cycle than has been customary.

**The balance of international payments** as published in the Year Book of the U. S. Department of Commerce, may be made a most valuable instrument in any system of control. This document, next to the internal balance sheet of the receipts and expenditures of the government, is the most important document prepared for the guidance of the general financial and business operations of this country.

A careful scrutiny of this balance sheet indicates that any further extension of foreign loans at this time is unwarranted on the basis of any practical possibility of increasing the counter-balancing items. A further disregard of these implications may lead to such serious involvements in foreign conditions

---

**"The stabilization of money is another possibility for large scale governmental and financial action. The seriousness of the lack of control of money value (or, the general price level as reckoned on a properly selected index) is beyond the power of words to express, because the world probably is in full movement on a secular decline with only minor short-lived upturns in prospect. It is important for governments and financiers to reconsider their attitudes on this question. A steadfast attempt to discover a safe and reliable means of controlling the value of money is required. Instead of being a question that is tabooed or ignored, it should be looked upon as the most important financial subject to which those in charge of the world's money can devote their energy and attention. There should be no rest until every possibility has been canvassed."**

---

as to make the recovery in this country less assured and decided, and that without compensating advantages to the world situation. The duty of those in control of the international financial operations of this country clearly lies in keeping a close eye on the balance of international payments to the end that no greater credit extensions be made than can be repaid by imports, foreign travel, and the like.

In the event world conditions should become increasingly chaotic, the organization of world finance and commerce will be best initiated in the smaller units of the national economic empires. The British Empire furnishes one such example and the United States and its dependencies another. Such limited organizations having non-predatory attitudes toward the rest of the world may offer the best hope for world progress in the immediate future.

> **"Decentralization of manufacture offers a useful method of striking a balance between agriculture and manufacturing. Only a few industries, such as that engaged in steel production, must be organized on a scale so large as to surround themselves inevitably with urban conditions. The present tendency to locate units in smaller communities should be encouraged for the sake of human as well as business values. Besides offering a greater stability to the life of the workman through the opportunity for gardens, poultry yards, and the like, it also furnishes a marginal region in which any needed interchange of manpower between manufacturing and agricultural activities could be made as changing conditions might require."**

Tools of control for the needed international flow of goods and credit lie in the government's supervision of the extending of foreign credits, and in the application of the tariff. Both the tariff and the control of credits should be viewed from the standpoint of this total situation in a way in which they do not appear to have been viewed in the past.

**The condition of agriculture** does not lend itself so readily to practical recommendations as do some of the other elements of the general economic problem that have been considered. However, to no other group would a stabilization of money be more helpful than to the farmers whom the deflation hit in full force long before it was felt by other industries. Agriculture has no inherent self-protection.

**Government reclamation policy** should be considered from now on with great care. No new areas should be brought under cultivation with public funds until every aspect of the resulting increased production has been canvassed. In fact, instead of reclaiming lands, it is possible that the government should be locating and purchasing marginal farm lands which should be reforested. This possibility already is being canvassed to some extent by the federal and state governments. It could be carried on and financed, by proper timing in the business cycle, in such a way as to improve the general situation.

**Profitable investment opportunities** must purposefully be searched out if this country actually is nearing a saturation point in mechanized equipment. Heretofore the demands for capital to supply new construction and manufacturing activities have absorbed the money available for investment.

What is there now of this same sort that will draw into profitable industry the idle millions of the years to come? Will it be the building of houses? If so, the cost of their construction will have to be diminished by new methods and by a better equalization of labor rates as between the building trades and those whom the buildings are to house, with due consideration to the annual earnings of building trades labor. When the investment market accustoms itself to a lower rate of return, capital will flow into this channel. Furthermore, the increased standard of living contemplated will enlarge the market for household furnishings, equipment, and conveniences.

Increased investment also is possible in small items totaling a large amount. Engineering analyses of the advisability of investments in new equipment by industries well established and running may well become a vital link in the maintenance of general economic prosperity in this country. The recognition of this by financial authorities and their organization to finance the multitude of small investment required may, in the aggregate, furnish a sufficient channel for investment to answer for many years the purposes of sustained prosperity. To make this effective, however, financial leaders must recognize the economics of the situation, and must consciously organize for this specific purpose. A helpful procedure would be to set up in each banking organization an engineering staff which should be as aggressive in searching for opportunities for sound investment as the sales departments have been in enlarging the lists of depositors.

This discussion again raises the question of *public works*. Herein lies an almost limitless field for the investment of private savings for public good that is socially profitable and economically stabilizing. To some extent the requirements may be realized and met by private initiative, but to a large extent it will have to be done by taxation. Moreover, it is in the interest of general business, when the rate of saving is larger than the rate of investment, to withdraw money from private hoarding and to use it for the public benefit. This is true because it is becoming plainly evident that money which is neither spent in consumption nor invested in capital goods is impotent in the hands of the one who saves. It does not benefit the saver, and it does injure society.

**Pensions,** unemployment insurance, life and disability insurance, and other similar industrial proposals deserve most careful study. The necessity, however, for such—private relief as is suggested, particularly unemployment insurance—will diminish in proportion to the success of the governmental action outlined herein.

**Trade associations** should be developed further. They should not only be permitted, but compelled to gather the basic information relating to their industries and to make public frequent and detailed reports on output, sales, stock in hand, unfilled orders, cancellations and capacity utilized. Such information would assist in planning everything that can be done industrially to maintain a steady flow of business. Ignorance of or inattention to such information in the past has resulted in entire industries adopting unwise policies which have contributed to economic unbalance. Sound methods should be developed for the introduction of new processes and machines into its field, so that industries may make needed changes with minimum economic disturbance and distress to individual workers.

Trade associations might profitably be required to set up not only standard principles and uniform methods for cost keeping, but also standard practises for financial reports to stockholders. Financial reports should be made public even though the securities of the companies are neither listed nor held by the public. Such a provision would encourage new money to flow into those fields where investment is likely to be profitable, rather than into those where a loss may be easily incurred. Associations should make a thorough, continuing study of consumer credit and installment selling. It would be most useful, at any given time, to know: whether installment buying were increasing or decreasing, whether payments were prompt or delayed, the proportion of returned goods. Information of this character would be exceedingly useful in developing policies of economic control.

**A shorter work-week** should receive the serious consideration of industry and commerce. The distribution of wealth between consumers and investors probably could be much improved by adopting new working hours and new overtime policies. For instance, it is reasonable to believe that if in an industry normally operating 50 hr. a week the working hours were shortened to 40, with 50 per cent overtime pay up to 45 hr. and 100 per cent overtime pay beyond that, the influence of the change would be in the direction of maintaining good business because:

1. Shorter normal working hours would constitute a permanent "spread of employment."

2. As business improved and the number of hours became too small, the overtime rate effective up to 45 hr. a week would assist in increasing the distribution to consuming power necessary to maintain the increased business. The extension of working time to where 100 per cent for overtime applied would add still more to consuming power.

3. The cumulative overtime would act as a damper to unwise expansion of activity. The business man would calculate more carefully before allowing rein to his enthusiasm. When he did conclude that the increased overtime was necessary his decision would be justified by the added consuming power involved.

Such a policy would have to be on an industry-wide basis, or the progressive and socially minded employers would be at a serious disadvantage.

**Employment agencies,** in a thoroughly coordinated country-wide system and with a well-trained and efficient staff, are essential. This is a pressing, unfilled need. Employment is a highly specialized problem and one of vital importance to any plan of controlling economic forces.

**Production by agreement** to reduce output, or the allocation of business to different firms is an unwise policy under normal business conditions. Such arbitrary control leads inevitably to stringent government regulation and official price fixing.

## GENERAL OBSERVATIONS

Although the issues discussed in this progress report have not been thoroughly studied, they comprise the broad outlines of the problem of economic balance, and they are subject to determination. There is an evident need for a more detailed and exhaustive consideration of them, and of others not mentioned.

Arbitrary control of modern industry and commerce in all their ramifications, complexities, and details, clearly is beyond the power of human beings; influences now at work must continue to govern its details. In particular, the profit motive and the active force of competition must be retained in such effective operation as will give society the benefit of the continuous improvement in methods and lowering of costs which they are capable of giving, but they must be restrained in their destructive and unsocial manifestations.

Since uncontrolled development has brought about so many undesirable results, there is justification for taking such chances as may be involved in developing rationally controlled economy. However, experimentation in social matters is serious, and therefore must proceed with wisdom and caution. The problem of the relation of consumption, production, and distribution is one of supreme importance and world-wide scope. There is no human problem which compares with it in difficulty, magnitude, or hopefulness. More and more, it must command the attention and devotion of the most intelligent, unselfish, and far-seeing men and women of the body politic.

> **"What is being contemplated is nothing less than the purposeful changing of the course of history. To such an undertaking the highest human capacities of our time must devote themselves."**

# Telephone Handset a Product of Research

**Many problems had to be solved before the handset type of telephone, now so popular with the public, became a practical reality. This article tells how some of these problems were solved, and how the characteristics of the present handset differ from those of the desk stand instrument.**

By
W. C. JONES
MEMBER A.I.E.E.
Bell Telephone Labs., New York

A. H. INGLIS
ASSOCIATE A.I.E.E.
American Tel. & Tel. Co., New York

ALTHOUGH the idea of mounting a transmitter and receiver on a common handle to form a handset was conceived soon after the invention of the telephone, and although handsets were in use by operators as early as 1878 only recently has it been possible to realize the convenience of this form of telephone set in the Bell system without undue sacrifice of performance as compared with the desk stand. For this reason the telephone system in this country has been built up in general around the desk stand which permitted the utilization of the available instruments to best advantage.

The greater difficulties inherent in the design of a handset as compared with a desk stand are due partly to a difference in the use of the instruments and partly to necessary differences in structure. The controlling difference in the use of the handset is due to the greater freedom permitted the user; this results in a wider range of positions for the transmitter, with a consequent tendency toward much greater variations in transmission characteristics and resistance. These variations may render the transmission unsatisfactory, and also may interfere with the operation of associated signaling and switching apparatus. The more severe handling of the handset transmitter also tends to accelerate aging.

Practically all commercial telephone sets are of the so-called "invariable" type in which the transmitter and receiver are connected to the line at all times while the set is in use. Therefore, part of the transmitter output is conducted to the local receiver; in addition the instruments are coupled to some extent through the air and, in the case of the handset, mechanically through the handle. If the amplification afforded by the transmitter is greater than the total losses in this side-tone path of receiver, air, and handle, sustained oscillation or "howling" may be set up. This condition is of course fatal to transmission; in practise it is necessary to operate well below the howling point to avoid serious transmission impairment from transient oscillations.

The handle of the handset definitely establishes the distance between transmitter and receiver: If it is too short, the user may not be able to hold the receiver on his ear with the transmitter in front of his lips; if it is too long, a transmission loss is introduced by the unnecessarily great distance between the transmitter mouthpiece and the user's lips. If the convenience of the handset is to be realized fully, the handle must be comfortable to hold and the complete handset must be light to avoid fatigue on the part of the user.

While many incidental problems have required solution during the development of the handset shown with its mounting in Fig. 1, this design is largely the result of a systematic attack upon the more fundamental problems which have been discussed. In describing the handset and its characteristics particular attention will be given to the features of importance in the solution of these problems.

## TRANSMITTER CONSTRUCTION AND CHARACTERISTICS

The transmitter is assembled in a die cast aluminum housing forming a unit which mounts in a threaded bushing in the handle. (See Fig. 2.) The molded phenol plastic mouthpiece, dome, and spacing ring insulate the electrical circuit from possible contact with the user. The carbon chamber of the transmitter is of the barrier type and differs materially from the ordinary direct-action type employed for years in desk stand transmitters. As may be noted, the diaphragm is insulated from the carbon. Both electrodes are stationary and are separated by a ceramic barrier; the electrode adjacent to the dia-

phragm is cylindrical; the other, hemispherical. This arrangement insures good contact between the carbon granules and electrode surfaces, and between the granules themselves, for all of the positions in which the transmitter is likely to be held. The resultant uniformity of resistance with position as compared with the conventional form of desk stand transmitter is shown in Fig. 3.

Low and relatively uniform carbon noise results from the uniform contact pressures and resistance of the handset transmitter. It may be noted from Fig. 4 that the carbon noise of the desk stand transmitter under handset conditions would be from 5 to 30 db. greater than that of the handset transmitter.

One of the unique features of the new handset transmitter is the location of the carbon chamber in front rather than in back of the diaphragm. By this arrangement the carbon granules are held in contact with the diaphragm in all positions of ordinary use; uniform output and faithful reproduction of speech sounds thus are obtained. In Fig. 5 is shown the difference between the output obtained with this transmitter and that secured with the desk stand direct-action transmitter.

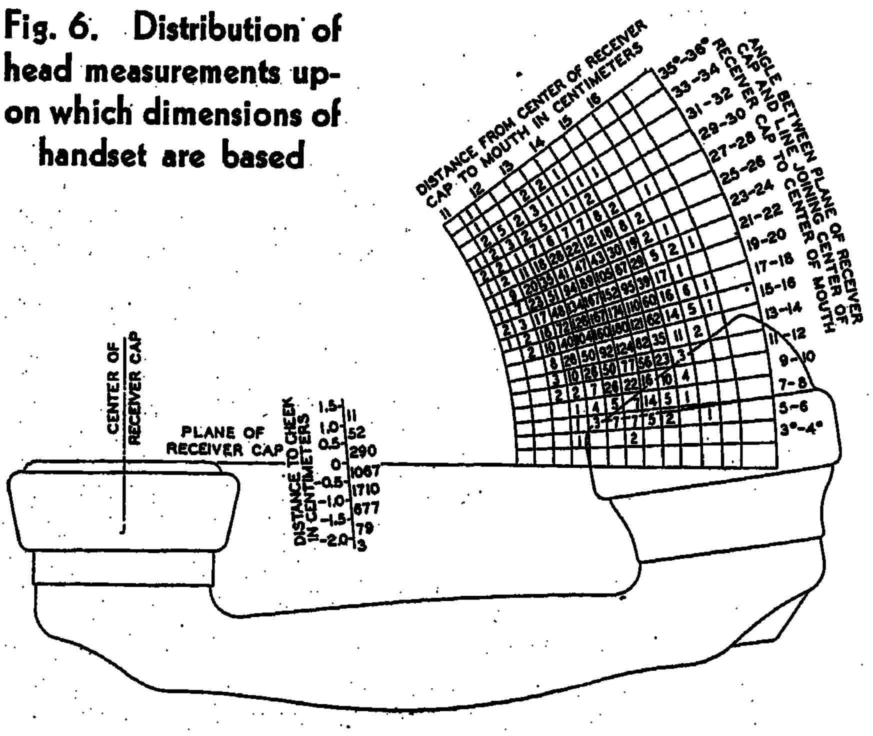
The diaphragm of the transmitter is made from thin duralumin formed into a truncated cone with radial stiffening ribs; this reduces its effective mass and provides sufficient rigidity to insure vibration as a unit throughout the operating frequency range. Several impregnated paper rings provide a resilient support for the diaphragm and add a certain amount of mechanical resistance. Appreciable improvement in response results from the lower mass and stiffness and the higher damping of the vibratory structure. Between 300 and 3,000 cycles per second the range in response is about 20 db. with this transmitter as compared with approximately 40 db. for the desk stand transmitter. A marked improvement in articulation results from this better response.

### Transmitter Aging

Characteristics of a granular carbon transmitter change with use; this is due to two principal causes the abrasive action of the granules upon each other, and the deterioration of the surface of the granules from high temperatures caused by excessive contact voltage. The former is known as *mechanical*, the latter as *electrical* aging. Aging of the desk stand transmitter is principally electrical, while in the handset it is largely mechanical.

Laboratory aging tests equivalent to about four years of handset service under severe conditions show that the change in the noise of the handset transmitter with age is of no practical importance. These tests show also that the output decreases somewhat and the average resistance increases materially during the life of instrument; the relatively small change in resistance with changes in position, however, effectively prevents the resistance from frequently becoming high enough to interfere with the operation of signaling apparatus in circuit with the transmitter. In this respect the new transmitter represents a notable improvement over earlier types.

**Fig. 6. Distribution of head measurements upon which dimensions of handset are based**



Method of filling the handset transmitter contributes materially to keeping the aging rate low. A machine taps the transmitter while it is being filled with carbon granules, so that the chamber is filled practically full instead on only about $^3/_4$ full as has been customary in the past. This reduces to a minimum the motion of the granules and changes in resistance which occur when the handset is placed on the mounting.

### Receiver

The handset receiver as may be seen from Fig. 2 is assembled in a die cast aluminum housing which screws into an insert in one end of the handle. The cap and spacing ring are of phenol plastic; they serve to insulate the electrical circuit from the user.

In general the receiver has been designed along conventional lines, but the choice of materials and design of the magnetic circuit have resulted in increased efficiency compared with the desk stand receiver. It has not been considered desirable to use this increase directly; the higher inherent efficiency of the receiver, however, is of appreciable indirect value for it has been utilized to improve the transmitting and receiving characteristics of the set, and to increase the stability of the receiver. These improvements have been effected without lowering the level of the received speech below that now obtained with the desk stand.

### Assembled Handset

Dimensions and proportioning of the assembled handset represent an effort both to meet the technical requirements and to produce a sturdy structure, light in weight and comfortable to hold, as well as attractive in appearance and in harmony with the mounting.

One of the major objections to the handset in the past has been its tendency to howl. Howling can be controlled in part by changes in the station circuit. It is desirable, however, that the handset be interchangeable with the desk stand without other changes in the telephone plant; therefore it has been designed to be inherently free from howling.

The solid phenol plastic handle employed in the present handset has a relatively high resonant frequency and provides a comparatively inefficient medium for transmitting between receiver and transmitter disturbances in the frequency range where the instruments respond most readily. Another factor in eliminating howling is found in the characteristics of the transmitter; its light and highly damped diaphragm does not respond readily to vibration set up by the receiver and transmitted through the handle, and under the worst conditions a margin of at least 15 db. against howling is realized with this structure.

Care has been taken in proportioning the handset to avoid an unnecessarily great distance between the lips and mouthpiece and to provide adequate clearance between the cheek and handle. Approximately 4,000 head measurements were made to determine the proper dimensions; these data are summarized in graphical form in Fig. 6. All but about 3 per cent of the persons measured can use the handset by holding the receiver to the ear in the usual manner; the others can do so by a slight shift of the receiver on the ear. The effect of this shift on the receiver speech is negligible compared with the average improvement in transmission resulting from the reduction in average talking distance.

## PERFORMANCE IN SERVICE

Since the initial introduction of the handset, close contact has been maintained with its performance by tests and observations under actual service conditions, and by examination of instruments returned from service. These observations have shown that, although as used by the subscriber the output of the handset transmitter to the line is somewhat lower than that of the most efficient desk stand transmitters, the improved response and articulation are adequate compensation for the lower level. Transmission performance of the handset has been found to be as good as, and probably on the average somewhat better than, that obtained with the desk stand.

Undesirable variations in transmission and resistance with change in position, excessive carbon noise, and howling, all of which heretofore have presented serious obstacles to the adoption of a handset for general use, have been overcome successfully in the design described. It has been found practicable to use this handset interchangeably with the desk stand in the existing telephone plant without important reactions on either transmission or signaling performance.

COMMUTATION theories usually deal with the reversal of the current in the commutating coil and with means for bringing about such reversal either along a straight line or a curve. The principal object in such studies is to accomplish commutation without excessive current densities under the brush. It is recognized that frequently it is impossible to realize this, but little attention has been paid to the fact that unless such ideal conditions are obtained, we actually have to deal with a switching phenomenon and that the problem should be analyzed with this in mind.

Let us assume that the circuit of armature coil 1 in Fig. 1 is about to be short-circuited by brush $B$ and that at this moment a voltage $e$ is induced in the coil by its rotation in the commutating field, or possibly by the stator field of an a-c. machine. It is evident that sparking in the minute point or edge of the brush $B$ which first touches the segment $a$ will be influenced largely by the speed with which the circulating current in the coil can build up as compared with the rate of increase of the area common to the brush and the segment $a$. This in turn means that the speed of the commutator will have an influence as well as the rate of increase of the circulating current. The latter is determined by the voltage $e$ and the self-inductance and resistance of the circuit of coil 1, if the coil carries no flux common to other closed circuits. This condition would exist if brush $B$ does not short-circuit any other armature coil and if the field winding $F$ is open-circuited, and under the further assumption that there are no secondary damping currents in the stator structure. Under these conditions the entire main flux $F$ and the leakage fluxes $L_a$ cause a rather high self-inductance in the armature coil 1, and consequently a slow building up of the circulating current. Fig. 2 represents a circuit equivalent to the armature coil 1 with the assumptions made so far.

The conditions change materially if the shunt winding $F$ is connected across the armature circuit as shown in Fig. 1, as well as across certain load circuits $L$ and various circuits of the generator $G$. We now have within the armature coil a leakage reactance flux $L_s$ and a mutual inductance $M$ between the armature coil and the field circuit. The latter in turn has a leakage flux $L_f$, and is closed partly through the armature circuit having resistance and inductance, and partly through several other circuits also having a resistance or inductance, or both; in other words, we have equivalent circuits somewhat as illustrated in Fig. 3. The rate of change in the circulating current now will depend upon all these factors, and therefore any change of constants in the field circuit or any of the other circuits may have a certain influence upon the commutating conditions. Similarly, any damping currents which can be induced in the solid portion of the stator yoke, or in coil

shield or damper windings surrounding the poles, may have an influence upon commutation. The various resistances and reactances shown in the secondary circuit of Fig. 3 are replaced by a single inductance $X_2$ and a single resistance $R_2$ in Fig. 4, which, while not fully equivalent to Fig. 1, somewhat simplifies the problem.

## OPENING THE CIRCUIT

All the various constants previously mentioned will have an influence also when the circuit of the coil 1 is opened while a circulating current is still flowing in it. There will be one difference, however, in that the high leakage and self-inductances helpful in the case of closing the circuit will be harmful in the opening because they considerably increase the energy to be dissipated in the spark which forms at the trailing edge of the brush. Mutual inductance, which aids in opening the circuit, as will be explained, is disadvantageous when the circuit is closed, since it allows a rapid building up of current. The effect of inductance on the opening operation may be made clear by following the switching operation in detail first for a machine with open stator circuits wound with one coil per slot, and a brush spanning one commutator bar, so that no account need be taken of mutual inductance between a commutating coil and any other closed winding. A circulating current is assumed to be flowing when coil 1 passes from under the brush.

When a circuit containing resistance and self-inductance such as shown in Fig. 2 is opened by the separation of contacts, in this case the brush and the bar, an arc or spark will be formed between the electrodes because at the last point of contact the temperature may become very high and "explosions" take place at this point, giving rise to sufficient energy density to establish the cathode spot of an arc on the negative electrode. As the contacts separate further the arc becomes longer and finally becomes unstable and vanishes. Any calculation of the decrease to zero of the circulating current due to commutator bars passing from under the brush must consider this short arc or spark formed. The arc characteristic, *i. e.*, the arc voltage as a function of the current through it, depends on the arc length. The latter in turn is varying and depends upon the way in which the arc is lengthened as a function of time; in other words, upon the speed of the commutator.

If the transient arc characteristic for a particular condition is known accurately, the energy dissipated in the arc can be calculated. This energy may be divided into two parts; the energy stored electromagnetically in the circuit, and the energy supplied to the circuit for the duration of the arc. In the case of the commutating coil, the latter energy may be supplied by the voltage induced in the coil by its rotation in the commutating field, or in an a-c. machine it can be induced also by transformer action between the stator field and the coil. Usually the total arc energy will lie between the values of once and twice the energy stored in the magnetic circuit. This stored energy varies directly with the self-inductance coefficient $L$ and the square of the current to be broken; hence the arc energy also depends upon these factors. The length of time during which the arc or spark is present also increases with an increased coefficient of self-inductance. Since a trailing edge spark is harmful in so far as it burns the commutator and brushes, it is desirable to keep the energy to be dissipated in the spark as low as possible. This can be done by lowering the self-inductance or reducing the current to be interrupted; also by the proper utilization of mutual inductance.

## EFFECT OF MUTUAL INDUCTANCE

As previously indicated, circuits having mutual inductance with a commutating coil are established by the field or stator circuit being closed through the armature and other circuits, or by damping currents in the stator structure. Other circuits having mutual inductance with the commutating coils usually exist if the winding is chorded, if there is more than one coil per slot, or if a wide brush is used; in fact, whenever the sides of at least two coils which are being commutated during a common time interval lie in the same slot. In this case the mutual inductance between coils must be considered. For example, if the brush is wide as shown in Fig. 5 and short-circuits the two armature coils 1 and 2, coil 1, which is about to be open-circuited, still has leakage fluxes $L_1$, but it also has mutual fluxes $M$ with the field winding as previously described, and mutual fluxes $M_a$ with the armature coil 2, the latter in turn having leakage fluxes $L_2$ of its own.

This may better be shown by the simplified although not fully equivalent circuit indicated in Fig. 6.

If such a circuit containing mutual inductance in addition to self-inductance and resistance is opened with a switch, the decrease of the current in the primary circuit again may be calculated if the transient arc characteristic curve is known. It is found that in this case all of the stored energy need not be dissipated in the switch. The decrease of current in the primary circuit will induce voltages in the secondary circuits such as to cause their currents to change. This means that part of the energy stored in the primary circuit may be transferred to the secondary circuits and dissipated as $I^2R$ loss in them or held in storage in the secondary circuits. Consequently, the energy dissipated in the spark may be, and usually is, reduced by introducing mutual inductions. The magnitude of the reduction depends upon the degree of mutual coupling between the circuits and upon the circuit constants, such as resistance and self-inductance, of all the circuits having mutual inductance with the commutating coil. It follows therefore that as conditions in the stator circuits change, the commutating condition may change also, although such factors as load current, speed, and commutating fields, which are usually considered as the only ones determining the commutating conditions, remain unchanged.

For similar reasons, different conditions of mutual inductance between the various armature coils will have an appreciable influence. The conditions of the mutual flux $M_a$ and leakage fluxes $L_1$ and $L_2$ in Fig. 5 will of course be appreciably different when the coils are located in separate slots than when the coils are located in the same slot. This difference leads to the frequently observed condition that certain commutator segments show more burning than others. These considerations also explain why frequently a split-throw of the armature coils improves commutation as a result of its effect upon the relation between leakage and mutual inductances of the coils. Without the split-throw a good transfer of energy from coil to coil in the same slot may take place, but the last coil in the slot is not well coupled to the first coil in the next slot; hence considerable energy must be dissipated when the circuit of the last coil in a slot is broken. The split-throw reduces this maximum dissipation of energy in the spark because at least one coil side of the coil under commutation is always closely coupled with another coil side; and assuming that the brush is wide enough to short-circuit the adjacent coil, better transfer of energy can take place. The beneficial effect thus produced consists not only in decreasing the maximum sparking but also in bringing about more uniform sparking on the different commutator bars, which in turn reduces irregular wear and differences in the heating of the bars; irregular heating of the bars if occurring to any marked extent is likely to cause differences in expansion of the bars and therefore mechanical irregularities in the commutator surface, with consequent further accumulative harmful effects upon commutation.

In all of the previous discussions upon the constants of the circuits which may influence commutation, only resistance and reactance have been mentioned. However, with the high frequencies of commutating currents, it is quite possible that at times certain capacity effects in the various circuits may exert an influence upon commutation conditions.

Having established the new concept of switching and the fact that the various machine and external circuits may have an influence upon commutation, a means has been found for explaining many other practical experiences which cannot be explained by the conventional commutation theories. It may be seen readily, for instance, that there may be a difference in commutation between shunt, series, or separately excited machines, between laminated or solid field structures, etc., although the speed, current, and commutating field are the same. It follows that in the case of a-c. commutator machines the commutation may be affected by the size and type of transformer to which the machine is connected and by various other factors.

Interesting results may be obtained with two series-connected motors on a motor car, especially in a-c. motors having no damping effects in their field structure. If in such a case the commutating impulses transformed into the fields of the two motors are exactly in opposition, no damping current can flow in the fields. Such opposition of voltages will occur if the relative position of the two commutators is such that the brush edge in one motor lines up with the mica insulation while in the other motor it happens to be in the center of the bar. If the relative commutator position changes so that the brushes in both motors will have the same position with regard to the mica insulation, the commutating impulses reflected in the fields will be in phase and damping current can flow, thus causing conditions entirely different from those previously mentioned. With two such motors on a motor car having slightly different speeds caused by a difference in the wheel diameters, periodic variations of commutation will take place. With the two motors connected in parallel across the same transformer, similar variations may take place. Even a change in design from

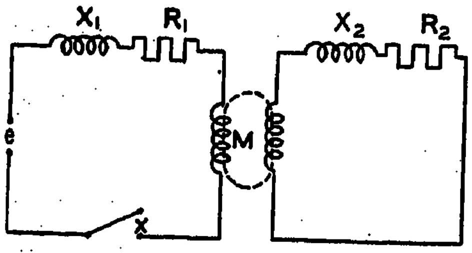

Fig. 4. (Above) Simplified diagram of the equivalent circuit shown in Fig. 3

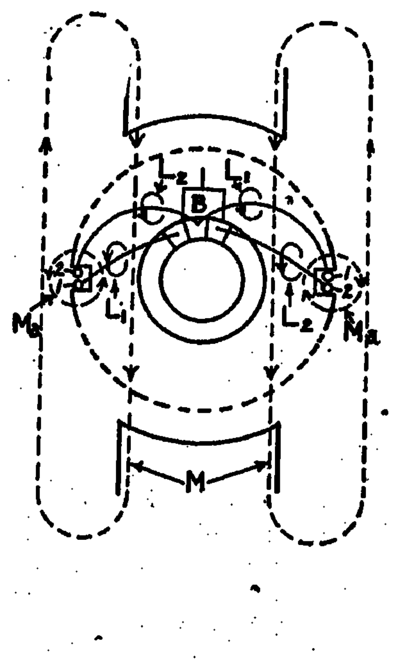

Fig. 5. (Right) Armature connections with two coils short-circuited by one brush

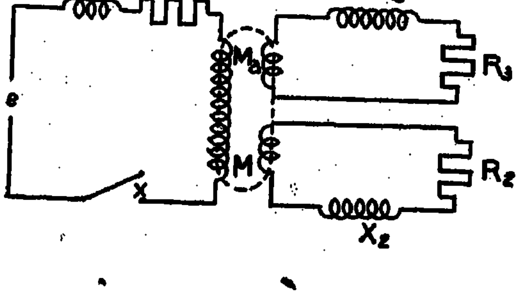
Fig. 6. Simplified equivalent circuit of Fig. 5



series to parallel connected fields in the motor may influence commutation. With such machines as phase-advancers or regulating machines connected to the secondary of induction motors, the switching theory readily explains differences in commutation which have been observed by the authors for different connections of such machines to various external circuits.

The introduction of the switching concept into the commutating problem is of course not necessary when ideal commutating conditions exist. There also are cases which approach the ideal sufficiently to make the consideration of the switching concept unnecessary in practise. Again, where the commutating conditions are not ideal but where the brush short circuits several armature coils, their mutual effect may be so predominating that the characteristics of the field and external circuits may have little influence. In general, however, the commutating phenomenon cannot be considered as completely analyzed unless the possibility of the switching phenomenon as influenced by the various circuits has been given due consideration.

# Cathode Drop in Arc Discharges

**There is no general agreement among physicists concerning the mechanism which produces a low cathode drop with the correspondingly high current density which is characteristic of an electric arc. Herewith is presented a review of prevalent theories regarding this phenomenon, and results of some experiments on arc and glow discharges.**

By
S. S. MACKEOWN
ASSOCIATE A.I.E.E.

California Institute of Technology, Pasadena

AN ARC is defined as an electrical discharge in a gas or vapor in which the cathode drop is of the order of 10 or 20 volts and the current density to the cathode spot is of the order of hundreds or thousands of amperes per square centimeter. In order for an arc to exist it is necessary that there be some mechanism for producing electrons at or near the cathode. As to the way in which these electrons are liberated there are three theories as outlined briefly in the following paragraphs.

1. Thermionic emission. This, the oldest theory, assumes that by the bombardment of positive ions the cathode spot is maintained at such a temperature that it is capable of emitting sufficient electrons to maintain the arc. For this to take place temperatures greater than 3,000 deg. cent. would have to exist at the cathode spot. These temperatures actually do exist in the case of the carbon and tungsten arc; but in arcs between less refractory metals such as copper or brass as well as in the mercury arc, no such temperatures are present at the cathode spot. In such cases thermionic emission cannot account for the liberation of sufficient electrons to maintain the arc.

2. A more recent theory is that positive ions are present close to the cathode in such large numbers that they produce an electric field sufficiently large to free electrons from the cathode by the attraction of the field alone. Calculations show that electric fields of the order of $10^6$ volts per cm. exist at the cathode in the case of both copper and mercury arcs; these fields are large enough to supply the electrons necessary for maintaining the arc.

3. A third theory proposes that the production of electrons is due to thermal ionization of the gas near the cathode. In order that there should be any appreciable thermal ionization in the gas, the temperature of the gas must exceed 4,000 deg. cent.; it is doubtful if such a high temperature obtains.

It seems probable therefore in the case of arcs between highly refracting electrodes, such as carbon and tungsten, that electrons are emitted from the cathode by thermionic action. In the case of arcs between less refractory electrodes such as copper or brass, electrons probably are emitted from the cathode by the action of the intense electric field existing at the cathode surface.

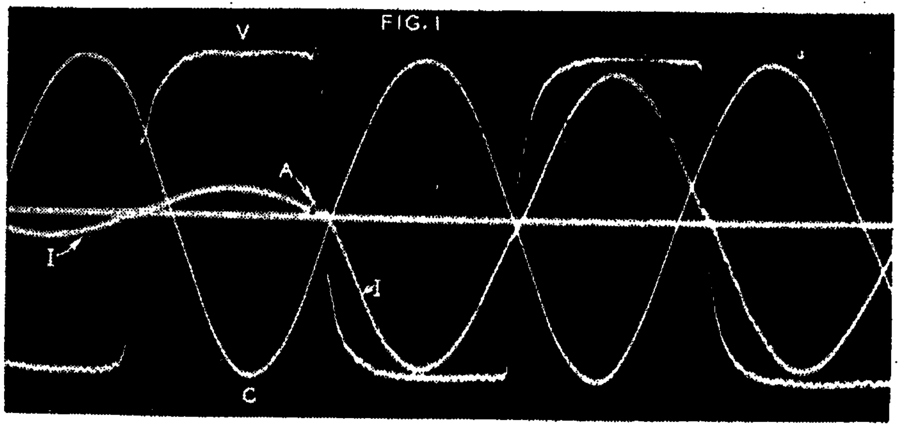


**Fig. 1. Current and voltage relations in the abnormal cathode drop; at point A the current was increased suddenly from 52 to 320 milliamperes**

## NORMAL CATHODE DROP IN THE GLOW DISCHARGE

In the glow discharge a much higher cathode drop exists than in the arc. If the current density to the cathode is below a certain definite value, the cathode drop is constant and is spoken of as the normal cathode drop. As the current density to the cathode is increased further the magnitude of the cathode drop increases, and the region over which it extends decreases. When the cathode drop increases with increasing current density it is spoken of as the abnormal cathode drop.

In the glow discharge as in the arc there must be some mechanism present to produce electrons at or

---

Based upon "Cathode Drop in Arcs and Glow Discharges" (No. 31M5) presented at the A.I.E.E. Pacific Coast convention, Lake Tahoe, Calif., Aug. 25–28, 1931.

near the cathode; the following theories have been proposed:

1. Positive ion bombardment of the cathode. It is known that electrons may be liberated by positive ion bombardment of a metal surface; however, when the normal cathode drop obtains it is doubtful if the positive ions hit the cathode with sufficient energy to produce any appreciable ionization; but when the cathode drop is abnormal, the positive ions possess much more energy, and under these conditions this mechanism may be the most important one.
2. Production of electrons by collision of positive ions with neutral gas molecules in the region of the cathode drop. In general this process occurs only when the positive ions possess energy greater than in the normal cathode drop.
3. Production of electrons from the cathode by photoelectric effect. It is believed generally that this process is inadequate to account for the required number of electrons necessary to maintain the discharge.
4. Production of electrons by metastable atoms arriving at the cathode. Because one of the electrons is in a high-energy level, these metastable atoms have enough potential energy to free electrons from the cathode. It is probable that in the case of the normal cathode drop this mechanism is important, especially when the rare gases such as helium, neon, or others are used.

Unfortunately, so far none of these theories has been developed so as to obtain quantitative agreement with experimental results. It is possible that two or more of these processes may take place simultaneously; also in some cases one of them may be most important, whereas in other cases another may be more prominent.

## Abnormal Cathode Drop

As the current to the cathode of a discharge tube is increased in the region of the abnormal cathode drop, the magnitude of the cathode drop increases and the distance from the cathode in which the cathode drop exists decreases. Both of these effects cause an increase in the electric field existing in the cathode drop. It is quite certain that as the current is increased, a greater portion of the current to the cathode is due to electrons leaving the cathode.

For the past several years considerable experimental work has been done on the abnormal cathode drop; the results of a few of the experiments are presented here. Preliminary measurements of the cathode drop, especially when the current to the cathode was large compared to that required to just cover the cathode with the cathode glow, gave quite inconsistent results. The first measurements were made with direct current, but soon it was found better to use alternating current and measure the cathode drop with an oscillograph.

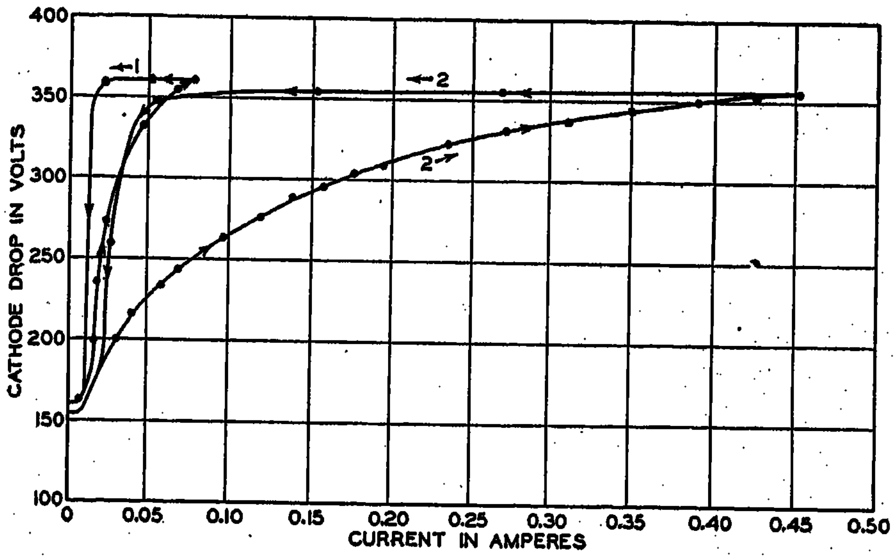

Fig. 2. Voltage of Fig 1 plotted against current

In Fig. 1 is an oscillogram which shows the relation between current and voltage in the abnormal cathode drop. Curve *I* represents the current through the tube, *V* the voltage across the tube, and curve *c* a calibration curve which in this discussion may be disregarded. At point *A* a resistance in series with the tube was short-circuited so that the current was increased from 52 to 320 milliamperes (r.m.s.). It is apparent at once that this change in current has only a small effect upon the voltage curve.

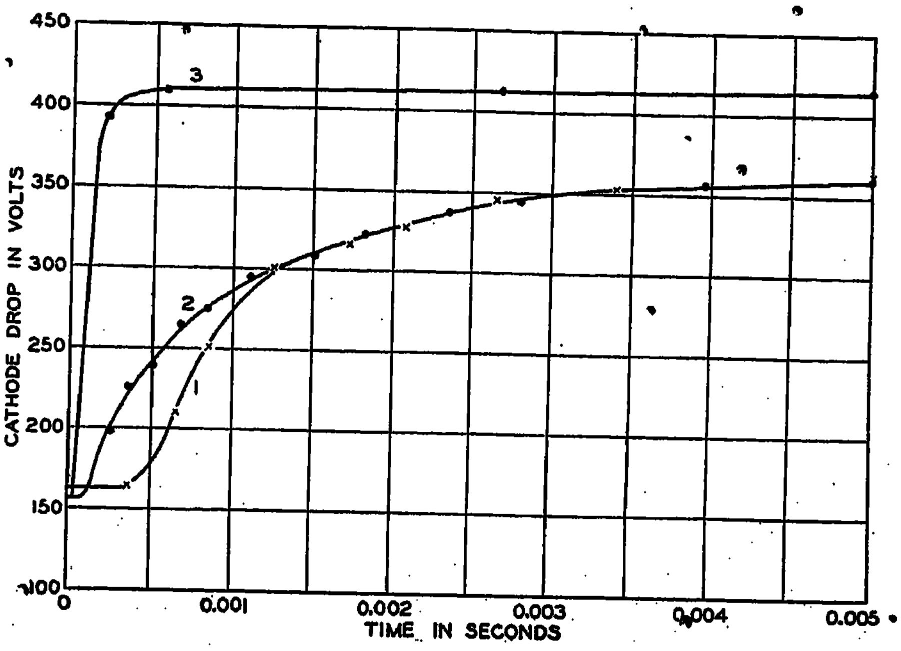

Fig. 3. Voltage of Fig. 1 plotted against time

In Fig. 2 the data from Fig. 1 are plotted with voltage and current as ordinates. This curve shows that the cathode drop is less for increasing values of current than it is for decreasing values. In Fig. 3 the data from Fig. 1 are plotted with cathode drop and time as ordinates. Curve *1* represents the data for increasing current when the effective value of the current is 52 milliamperes; curve *2* for a current of 320 milliamperes, and curve *3* for a current of 4 amperes. The difference between curves *1* and *2* for low values of time can be explained by the fact that the abnormal cathode drop occurs at an earlier time when the current is high than when it is low. If allowance for this is made it is apparent that the cathode drop requires approximately the same time to build up in the two cases where the current is 52 and 320 milliamperes, respectively. Curve *3*, however, shows that the cathode drop builds up much more rapidly when the current is high; this difference is explained as follows: In the case where the current is low, the cathode drop is formed by the positive ions from the main body of the gas congregating near the cathode, a relatively slow process. When the current density to the cathode is high, the cathode drop is due to the ionization of gas molecules near the cathode caused by electrons leaving the cathode and by the rapid dispersion of electrons away from the neighborhood of the cathode. Since electrons move hundreds of times more rapidly than positive ions, this latter process takes place much more rapidly. This leads to the conclusion that when the current density is high, a large part of the current to the cathode is carried by electrons leaving the cathode.

### TRANSITION FROM GLOW TO ARC

The transition from a glow discharge to an arc is illustrated by Fig. 4. When this transition occurs, the voltage (curve *V*) shows a sudden decrease which corresponds to the decrease in cathode drop. Current through the tube is represented by curve *I*; its effective value was 4 amperes. The fact that sometimes an arc is formed and sometimes not, probably is due to the fact that the surface of the cathode is constantly changing because of the rapid sputtering or disintegration that occurs in the glow discharge with such high current densities.

A consideration of results from several oscillograms similar to Fig. 4 leads to the following explanation of the process by which a glow discharge changes to an arc: As the current to the cathode is increased in the glow discharge, a larger portion of current is due to electrons leaving the cathode; these electrons are not emitted uniformly from the cathode surface, but come primarily from small portions of the cathode, which because of some impurity are especially active. These electrons produce ionization in the region of the cathode drop, this ionization being greatest in the vicinity of the active spots. Due to their high mobility, the electrons leave this region much more rapidly than do the positive ions. A high space charge results, increasing the electric field in the vicinity of these active spots as well as the number of electrons emitted therefrom. This process is cumulative and proceeds rapidly until the electric field near one of the spots increases to an amount sufficient to produce electrons from the cathode by the attractive force of the field alone. When this occurs, an arc is formed with its low cathode drop and extremely high current density to the cathode spot.

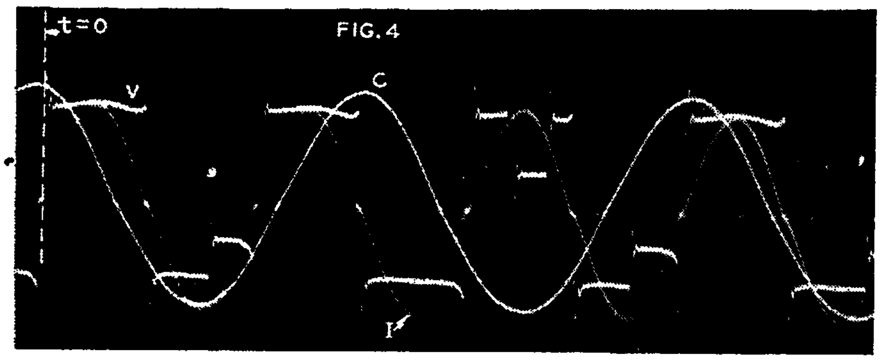

**Fig. 4. Current and voltage relations during transition from glow to arc**

This explanation is based upon arcs at low pressure; it is probable, however, that the same process is effective at atmospheric pressure, and occurs every time the current in an a-c. arc passes through zero, except when the electrodes are so refractory that they can support a high enough temperature to produce a large electron current by thermionic emission.

# Transient Oscillations in Coupled Windings

**A mathematical study of the oscillations occurring in a pair of mutually coupled windings, the primary and secondary of a transformer, when one of the terminals is subjected to the impact of a traveling wave, has been completed. The general conclusions reached in this study are summarized in the following article.**

By
**L. V. BEWLEY**
ASSOCIATE A.I.E.E.

General Elec. Co.,
Pittsfield, Mass.

IN THE PAST, the mathematical analysis of transient oscillations in transformer windings has been based upon a single winding having self-inductance and mutual inductance between its turns, capacitances along the stack and to ground, and in one instance, resistances to represent the losses. Such a circuit ignores the presence of secondary circuits, but, strangely enough, proves quite adequate to describe the internal high-frequency transients of the winding under consideration, not only qualitatively, but quantitatively as well.

Cathode ray oscillograms, however, do show some difference in the characteristics of the oscillations, depending upon the terminal connections of the secondary circuits. This is particularly true in the case of an isolated neutral primary winding, where a change from an open-circuited to a short-circuited secondary may bring about considerable changes in the frequencies of oscillations. This shift of frequencies has been attributed loosely to a change in the effective inductance of the circuit, brought about by closing the secondary circuit; just as the natural frequency of a simple lumped inductance-capacitance series circuit is changed if the inductance is reduced by short-circuiting a coupled winding. In addition to the above limitation of the single winding theory of transformer oscillations, there was nothing in the equations relative to the internal oscillations of the secondary circuit.

The complete idealized circuit of a two-winding transformer is shown in Fig. 1. The primary winding, on which the traveling wave is assumed to impinge, is designated as winding 1, and all associated voltages and currents have the corresponding subscript as $e_1$, $i_{c1}$, $i_{k1}$, and $i_{L1}$. The secondary winding is

---

Based upon "Transient Oscillations of Mutually Coupled Windings" (No. 32-4) presented at the A.I.E.E. winter convention, New York, N. Y., Jan. 25-29, 1932.

designated as winding 2. The terminals are shown connected to impedances $Z_1$, $Z_2$, $Z_3$, and the incoming surge impedance $Z$. Each winding has capacitance $C$ and $K$ to ground and along the stack, respectively, and an effective self-inductance $L$. The two windings are coupled magnetically by an effective mutual inductance $M$, and electrostatically by capacitance $C_3$. It is pertinent to remark at this point that the effective inductances of the circuit include the partial interlinkages, on certain assumptions, and are not simple, uniformly distributed constants. The necessity for these more complicated assumptions is responsible for greatly increasing the complexity of the problem.

The application of Kirchhoff's laws to the elements of the circuit shown in Fig. 1, permits the partial differential equations of the circuit to be written. A solution then is found such that the terminal and boundary conditions are satisfied.

The initial distribution caused by the impact of an abrupt wave front depends only upon the capacitance elements of the circuit, because the currents through the capacitive paths are infinite for an infinite rate of change of voltage, whereas the currents in the inductive paths are all zero at that first instant. Thus the circuit which is effective for calculating the initial distribution may be simplified by eliminating the inductances shown on Fig. 1.

The idealized circuit of Fig. 1 is free of losses, and therefore stabilization does not occur (theoretically) unless the terminal impedances have losses. For zero or infinite values of the terminal impedances the oscillations never do subside, but persist forever. However, any actual circuit possesses some losses, and consequently the oscillations eventually die out and the currents reach permanent values, so that there is no change of flux and there are no induced voltages. The distribution of voltage in the primary winding is then uniform, ignoring the conductance from the winding to ground, and the potential of the secondary is constant throughout the winding. Thus while the realization of these final distributions is contingent upon the presence of losses, either in the circuit itself or in the terminal impedances, nevertheless there are fixed axes of oscillation about which the transient oscillation of the no-loss circuit take place.

The complete solutions have not been attempted, except for zero and infinite values of the terminal impedance; that is, for grounded and isolated terminals. The solutions which have been worked out are also restricted to rectangular, applied waves. The response to waves of arbitrary shape can always be found in the usual way by an application of Duhamel's theorem, as described in a previous paper, "Transient Oscillations in Distributed Circuits," by L. V. Bewley, A.I.E.E. Trans., v. 50, 1931, p. 1215–33. The solutions are in the form

$$e = \text{(final distribution)} + \Sigma \text{ (harmonic space and time oscillations)}.$$

The time harmonics are always *cosine* functions, and since Duhamel's theorem is operative only on the *time* functions of the solution, the response to different arbitrary wave shapes may be written down by inspection from the corresponding solutions given in the previous paper, where the time functions were also harmonic *cosine* oscillations.

## CONCLUSIONS AND FINDINGS

As far as a description of the transient in the primary winding is concerned, both qualitatively and quantitatively, it is not necessary to consider the influence of the secondary winding beyond keeping in mind that its terminal conditions will change the relative importance of the natural frequencies of oscillation. But these changes in frequency can be accounted for quite adequately by changing the effective inductance in the equations.

The transient in the two-winding circuit consists of an infinite series of space and time harmonics, oscillating about the final distribution as an axis of oscillation. The amplitudes of these harmonic oscillations depend upon the initial and final distributions, and are in fact given by the Fourier analysis of the difference between them.

The space harmonics which appear in the solution are decided by the Fourier series chosen to represent the initial distribution throughout the length of the winding. The fundamental wavelength upon which the Fourier analysis is made is dictated by convenience in any specific case, and is therefore more or less arbitrary. Thus for certain terminal conditions, a full range *cosine* series may prove the most appropriate, while in another case a half range *sine* series may lead to the greatest simplification.

To each space harmonic there correspond two distinct time harmonics; that is, each space harmonic consists of two components vibrating at widely different rates. The amplitudes of these two time

$C_1$ = capacitance of primary winding to ground
$C_2$ = capacitance of secondary winding to ground
$C_3$ = capacitance between primary and secondary windings
$K_1$ = capacitance between ends of primary
$K_2$ = capacitance between ends of secondary
$L_1$ = effective self-inductance of primary
$L_2$ = effective self-inductance of secondary
$M$ = effective mutual inductance between windings
$Z$ = surge impedance of line at primary
$Z_1(p)$ = grounding impedance of primary neutral
$Z_2(p)$ = terminal impedance of secondary, neutral end
$Z_3(p)$ = terminal impedance of secondary, line end
$E$ = terminal voltage of primary due to traveling wave
$p$ = $\partial/\partial t$ = partial time derivative
$t$ = time
$i_{c1}\ i_{k1}\ i_{L1}\ i_{c2}\ i_{k2}\ i_{L2}\ i_{c3}$ = currents through $C_1$ $K_1$ etc.
$e_1$, $e_2$ = instantaneous voltages at any point $x$ of primary and secondary, respectively
$x$ = fraction of total winding from neutral end
$l$ = 1 = total length of winding.

harmonics are usually quite different, but by a change of terminal conditions, it is possible to change their relative importance.

The harmonic frequencies of the secondary circuit are the same as those of the primary winding, but the amplitudes bear a ratio to the corresponding amplitudes in the primary which depends upon the order of the space harmonic. In other words, there is no fixed proportionality between the oscillations in the two circuits.

The oscillations corresponding to an infinite rectangular applied waves start simultaneously throughout the windings, and the time harmonics are all *cosine* functions. The response to applied waves of arbitrary shape can be obtained by an application of Duhamel's theorem.

# Coordination of Line and Transformer Insulation

**The coordination of transformer insulation with line insulation recently has been discussed widely, and sentiment has changed gradually in favor of the use of an air-gap for purposes of coordination as against the practise of reducing the line insulation near the substation. Standards of dielectric strength and air-gap spacing in accordance with this trend are presented herewith.**

By
**V. M. MONTSINGER**
FELLOW A.I.E.E.

Pittsfield, Mass.

**W. M. DANN**
FELLOW A.I.E.E.
Westinghouse Elec. &
Mfg. Co., Sharon, Pa.

AT THE Toronto convention of the Institute in June 1930, a paper "Recommendations on Balancing Transformer and Line Insulations on Basis of Impulse Voltage Strength," by V. M. Montsinger and W. M. Dann, A.I.E.E. TRANS., v. 49, 1930, p. 1478–81, sponsored by the transformer subcommittee of the electrical machinery committee, was presented to bring before the membership the status of certain work done by the subcommittee in connection with the coordination of transformer and line insulation.

Two things of interest and importance were included in this paper: first, a recommended practise of expressing the impulse strength of a transformer in terms of the 60-cycle dry flashover of suspension insulators; and second, recommendations for coordinating the impulse strengths of the transformer and the line insulation. These recommendations included either the use of a safety gap of known flashover characteristics connected in parallel with the transformer, or the reduction of the line insulation to a coordinating value for a distance of half a mile from the transformer, or a combination of either with a suitable lightning arrester.

Since the publication of this paper the principle of coordination has been discussed widely and it appears to have become accepted in a general way throughout the industry. It seems, however, that there has been a gradual change in sentiment in favor of the use of an air-gap for purposes of coordination, as against the practise of reducing the line insulation. Several reasons have contributed to this shift of sentiment. For example, the idea of having a flashover occur out on the line, even though restricted to a distance of half a mile, seems to be unacceptable to operating engineers, and opinion seems to favor having the flashover occur at an accessible point near the transformer. Any degree of line over-insulation made desirable by local conditions in the vicinity of the station becomes feasible if the coordinating gap is used. Furthermore, a string of insulator disks if used for coordinating purposes affords less chance for a reasonable adjustment of coordinating values. The removal of one disk, for example, from a string of eight, causes a change of approximately $12^{1}/_{2}$ per cent in the impulse flashover value. The difficulties of adjustment naturally are even more pronounced with shorter strings. In contrast with these difficulties, air-gaps may easily be set for any desired degree of adjustment.

The transformer subcommittee has recognized the growing sentiment in favor of a gap for coordinating purposes, and it is the purpose of this brief progress report to bring to the attention of the Institute membership the following revisions which have been made in the previous recommendations.

## IMPULSE STRENGTH OF TRANSFORMERS

The yard stick used to express the impulse strength of a transformer has been changed from the 60-cycle flashover value of a given line insulator to a coordinating gap with a given length in inches, as outlined in the following paragraphs:

(*a*) *Transformers Receiving Standard Tests as Specified in Par. 13-400, A.I.E.E. Standards No. 13.* Apparatus conforming with the standards of dielectric strength should be so designed that its impulse strength against lightning is greater than the impulse flashover voltage to earth of an air-gap whose spacing is in accordance with Table I. This spacing is between the ends of two square-cornered, square-cut, co-axial rods not more than $^{1}/_{2}$ in. thick and so mounted that the rod overhangs its support at least one-half the gap spacing. The insulators used as supports should meet the N.E.M.A.-N.E.L.A. 60-cycle flashover requirements for the line voltage.

(*b*) *Transformers Receiving Other Than Standard Test.* For trans-

M. Montsinger, *chairman*, W. H. Cooney, W. M. Dann, H. C. Louis, Basil Lanphier, L. C. Nichols, George Vaughan, F. J. Vogel.

formers receiving a test different from that given for the rated circuit voltage in (*a*) the gap spacing should correspond to the test which the transformer will receive, in accordance with the relation between test and gap spacing given in (*a*).

### RECOMMENDATIONS ELIMINATED

The "Recommendations for Coordinating Transformer Insulation with Line Insulation in the Field," included in Part II of the Montsinger-Dann paper of June 1930, will be eliminated from the recommendations of the subcommittee. These recommendations involve the three methods of coordinating transformers with line insulation referred to in the opening paragraphs of this report. The coordinating gap replaces the eliminated recommendations and serves the following purposes:

1. It establishes the standard of impulse strength required in the design of a transformer.
2. In practise, it limits the magnitude of incoming surge voltages to values less than the impulse strength of the transformer, thereby establishing coordination.
3. A lightning arrester may be used in conjunction with the coordinating gap to prevent system outages.

**Table I—Air-Gap Spacings**

| Rated Circuit Voltage | Transformer 60-Cycle Test Voltage | Spacing of Air-gap |
|---|---|---|
| Kv. | Kv., r.m.s. | Inches |
| 13.8 | 28.6 | 4.25 |
| 23 | 47 | 6.25 |
| 34.5 | 69 | 9.25 |
| 46 | 93 | 12.25 |
| 69 | 139 | 18.75 |
| 92 | 185 | 25.00 |
| 115 | 231 | 31.5 |
| 138 | 277 | 38.25 |

| 196 | 393 | 54.5 |
| 230 | 461 | 64.0 |

# Development of the Waukegan Station

**The reasons for the development, choice of site, and general plan of the Waukegan station are outlined briefly in this article. The three major periods of development are covered, the article serving as an introduction to the two companion articles "Waukegan Features New Electrical Design" and "A 115,000-Kw. Turbo-Alternator," which follow.**

By
J. L. HECHT
MEMBER A.I.E.E.

Public Service Co. of
Northern Ill., Chicago

THE WAUKEGAN station of the Public Service Company of Northern Illinois is located approximately 40 miles north of Chicago at the extreme northeast limits of the city of Waukegan on the west shore of Lake Michigan. This station, with an installed capacity of 290,000 kw., performs the dual function of supplying energy to a metropolitan system and to a surrounding transmission system.

During the year 1916, in giving consideration to load development and corresponding facilities for generating capacity to take care of this load, it became increasingly evident that the future demands for electricity in the Chicago metropolitan district would require substantially larger power station developments than had been considered heretofore. It was evident also that it would be necessary to locate such developments on Lake Michigan where an unlimited supply of condensing water was available.

As a result of these conclusions, a careful survey was made of all suitable power station sites, bearing in mind those fundamental requirements of adequate water supply, transportation facilities, expansion space, rights-of-way for disposing of energy generated, and proper correlation with respect to the load area to be served. This survey revealed that the power station sites most suitable for development to supply the Chicago metropolitan district were at Waukegan on the north, and at the Illinois-Indiana state line on the south. In the intervening distance of 50 miles along Lake Michigan no other suitable sites were adequate or available.

On the southern site the initial development of the commonly known State Line station of the Chicago District Electric Generating Corporation has taken place. The northern, Waukegan, site was acquired in 1917. The original site comprised 87.6 acres with 1,223 ft. of shore line on Lake Michigan. This has been increased since to a total of 198 acres and 3,249 ft. of shore line The site could be served from two good coal-bearing railroads with a possibility of harbor development, and was suitably located for the acquisition of private rights-of-way to dispose of the large volume of energy it was proposed to produce. A private right-of-way 250 ft. wide was acquired. This connects with its three branches consisting of a 135 ft. southerly right-of-way to Chicago, a 150 ft. northerly right-of-way

---

Based upon "Development of the Waukegan Station of the Public Service Company of Northern Illinois" (No. 32M9) presented at the A.I.E.E. Great Lakes District meeting, Milwaukee, Wis., March 14-16, 1932.

to Milwaukee, and a 150 ft. westerly and southerly right-of-way which surrounds the Chicago metropolitan area.

At the time the site was acquired, it was thought that the first transmission lines for carrying bulk energy would be at 66 kv. and possibly a 132-kv. development could be expected later. It was fortunate that by the time the initial station development took place it was practical to proceed with 132-kv. transmission with its corresponding increase in capacity.

### INITIAL DEVELOPMENT PERIOD

Ground was broken for the initial development of the station on August 23, 1922, and the first unit of 25,000 kw. capacity was placed in service October 11, 1923. Unit 2, for 35,000 kw., was placed in service April 6, 1925. Both units 1 and 2 operate at 350-lb. pressure with a total temperature of 675 deg. fahr. with no reheat. Three boilers serve each unit. These boilers are equipped with chain grate stokers, and it is of interest to note that this was the first successful application of alternating current to variable speed individual stoker drive, the speed variation being approximately 40 per cent with a flexibility about equal to that obtainable with d-c. motors. Generation is at 12 volts, kv., the switching equipment consisting of the conventional cell type construction with a Cory system of interlocks.

At this period of the development it was thought that the ultimate capacity of the station would be of the order of 200,000 or 300,000 kw.

### SECOND DEVELOPMENT PERIOD

Unit 3, of 50,000-kw. capacity, went into service June 22, 1927. The operating steam pressure was raised to 600 lb. with a total temperature of 725 deg. fahr. A radical change in the type of electrical equipment was made with the installation of this unit, this change being the first complete installation in this country of metal-clad switching equipment for power station service.

For years electrical engineers of this country had considered metal-clad equipment but believed its development unsuited to American capacities and conditions despite the fact that it had been used extensively and successfully in England for many years. Naturally enough, the first installation carried with it some grief. However, the experience gained suggested future improvements and demonstrated the practicability of this type of switching equipment with its many inherent advantages over the conventional open type installation.

The continued results obtained with the metal-clad switchgear on unit 3 were so universally satisfactory from engineering construction and operating considerations that the exclusive use of this type of gear was adopted as a policy for all future power station and substation installations or additions.

A few of the outstanding advantages of metal-clad switchgear are:

1. Hazards to personnel are eliminated almost completely.
2. The carrying on of construction work is simplified and expedited.
3. Almost complete salvage value is obtained when the growth of the system compels replacement.
4. Costs are no more when all factors, including building structures switch cells, and bus compartments, are taken into consideration.

Unit 4, of 65,000-kw. capacity, was placed in service May 10, 1930. The use of pulverized fuel was decided upon prior to the installation of this unit. A thorough investigation was made of existing installations and a decision was reached to adopt the unit system with ball and table type mills. The operating steam pressure and temperature is the same as for unit 3 with the exception that an important change in the steam cycle was instituted. Steam is bled from the turbine at approximately 200-lb. pressure from the thirty-second row of buckets and reheated to a total temperature of 725 deg. fahr. One of the three boilers supplying the unit is of the reheat type. Generation continued at 12 kv. similar to the three previous units and, continuing the policy referred to above, metal-clad switchgear was used as on unit 3. Following is a tabulation of station performance for units 3 and 4 for the month of July 1931, using southern Illinois coal with a moisture content of approximately 13 per cent:

| | |
|---|---|
| B.t.u. per lb. of coal | 11,469 |
| B.t.u. per kw-hr. output | 13,299 |
| Lb. of coal per kw-hr. output | 1.16 |
| Monthly load factor (per cent) | 44.1 |

### THIRD DEVELOPMENT PERIOD

Unit 5 of 115,000-kw. capacity went into service September 1, 1931. With the installation of this unit an important departure was made in the switching arrangements. The generator bus was eliminated and the generator, together with its 120,000-kva. transformer bank stepping up to 132 kv., were considered as a unit, all switching being done at 132 kv. Again in accordance with the policy previously referred to, metal-clad switchgear was used. The use of this equipment on the 132-kv. installation marks the first of its kind in the world.

A further investigation of pulverized fuel mills led to the use of the tube type unit mills on unit 5. While this type of mill requires more power than the ball and table type mill, particularly during light load operation, it was thought that the maintenance problem would be simplified. These mills have not been in operation long enough to determine definitely characteristics of flexibility of operation or to make a general comparison with the ball and table type mill. Each of the three boilers supplying this unit is served by three mills with a capacity of 25,000 lb. of coal per hr., respectively. The steam cycle is similar to unit 4, steam being bled from the thirty-first row of buckets for reheat to 750 deg. fahr. One of the three boilers on unit 5 is equipped for reheat.

With the addition of unit 5 bringing the station capacity up to 290,000 kw., it was considered advisable to supplement the coal handling system with a rotary car dumper. This installation is unique in that the complete system, including the mule haul which pushes the loaded cars up an incline to the dumper, was developed for a-c. operation.

Application of a-c. motors to individual variable speed stoker drive and to coal handling equipment came about as a result of a policy adopted in 1906. It was felt that in order to stimulate the development of a-c. flexibility it would be advisable for the company to insist upon the use of a-c. equipment and to share with the manufacturer the grief and expense certain to be encountered in such a development. The experience derived from each case, while somewhat unpleasant at the time of development, has resulted in the complete and successful adaptation of a-c. drive to the various pieces of equipment considered. This in turn has been decidedly helpful to the power sales organization.

### FUTURE DEVELOPMENT

The present station capacity of 290,000 kw. covers what was thought to be the complete development at the time the first unit was installed in 1923. A definite prediction at this time as to the ultimate development of the Waukegan station would be to place one in the tenuous position of all prophets. However, it would appear far safer to predict a figure of 1,000,000 kw. than 500,000 kw. Bearing this in mind, it was necessary to give serious consideration to transmission facilities for future station output. The earlier 132-kv. circuits to Chicago were designed for approximately 90,000-kva. capacity and consisted of 300,000-cir. mil conductors. The latest circuit installed in 1930 consisted of 750,000-cir. mil conductors with a carrying capacity of approximately 180,000 kva.

A station which in its development over a 10-year period finds its last installed unit practically five times the size of its first unit, certainly offers a challenge to the engineer—a challenge to coordinate the successive developments so as not to nullify any preceding investment and at the same time to take advantage of the developments in the art to obtain an efficient workable station as a whole. Waukegan station, it is felt, meets these requirements.

# Waukegan Features New Electrical Designs

**Three new electrical developments incorporated during the last development period of Waukegan station are described in this article. They include the first 132-kv. metal-clad switchgear ever used, a 115,000-kw. single-shaft turbo-alternator the rotor of which was the largest forging ever made in this country, and a coal-car mule for which a new scheme of a-c. drive was developed.**

By
E. C. WILLIAMS
MEMBER A.I.E.E.

Public Service Co. of
Northern Ill., Chicago

THE THIRD and most recent development period at the Waukegan station of the Public Service Company of Northern Illinois includes two outstanding features: namely, the first 132-kv. metal-clad switchgear ever used, and a 115-kw. single-shaft turbo-alternator.

During the previous development periods, described in the preceding article "Development of the Waukegan Station," an open type steel structure for 132-kv. switching had been installed which included a number of rather unusual features, due partly to the fact that it was necessary to conserve space in one direction, whereas there was ample space in the other direction. As the main bus is located above the other equipment in the middle of the structure, it appears that there are three buses. However, the line and transformer buses are connected so that they form a rectangular ring bus with the main bus in the middle. The line and transformer reserve buses may be sectionalized by means of an oil switch of load-break disconnecting switches.

### 132-KV. METAL-CLAD SWITCHGEAR

The 132-kv. metal-clad switchgear consists of two double-bus units installed as shown in Fig. 1. One of these units is for switching the high voltage side of the 120,000-kva. transformer bank supplied by generator 5, and the other is for a 132-kv. transmission line. The buses of these two units are connected to, and form an extension of, the main and reserve buses in the open type steel structure. These two double-bus switchgear units are arranged as indicated in Fig. 2, and consist of oil filled cable buses and interconnections, special motor driven disconnecting switches enclosed in metal housings, oil switches equipped with potheads instead of outdoor bushings, and special bus connections and disconnecting devices for the instrument transformers.

The switchgear is rated to carry 1,200 amperes and the oil circuit breakers will interrupt 2,500,000 kva. at rated voltage. The capacity of the buses may be increased to 2,400 amperes by installing another set of buses. The present buses consist

---

Based upon "Electrical Design Features of Waukegan Station" (No. 32-57) presented at the A.I.E.E. Great Lakes District meeting, Milwaukee, Wis., March 14–16, 1932.

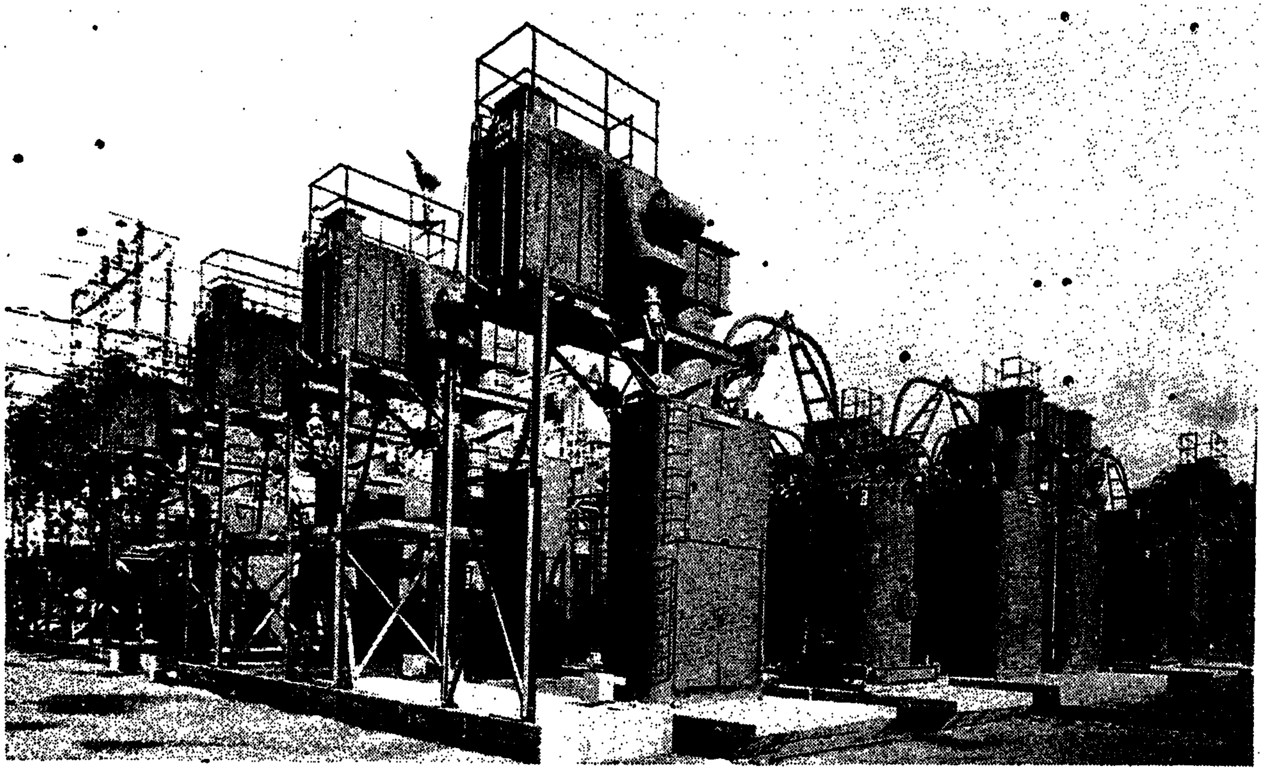

Fig. 1. The 132-kv. metal-clad switchgear, part of unit 5 installation, is the first ever used

of 3,020,000-cir. mil, oil-filled, paper-insulated, lead-covered, copper-armored cable. Isolated racks support the bus cable about 9 ft. above the switchgear foundations as it loops from switchgear unit to switchgear unit. The ends of each of these bus cable loops are insulated, and the midpoint of each cable sheath in each loop is grounded to keep the induced voltage in the cable sheath at a minimum.

The disconnecting switch consists of contacts in an oil filled tank equipped with entrance bushings which in turn are enclosed in an outer housing. The tank as well as the bushing on the bus side is raised and lowered by a motor driven mechanism, and overtravel is prevented by limit switches. When the tank is lowered, the circuit is opened under oil and the bus contact on the entrance bushing withdraws from its bus receptacle, thus providing a visual separation which through a sight glass may be observed from the outside of the housing. The bus receptacle consists of a hollow porcelain shell that forms a part of the main structure into which the entrance bushing on the disconnecting switch tank enters. The opening in the lower end of this porcelain shell is automatically covered by a metal cover when the disconnecting switch is withdrawn. These switches are operated in groups from the oil circuit breaker control panel, or individually at the disconnecting unit.

As it is seldom necessary to disconnect a potential transformer, this disconnecting device is not motor operated. A portable motor, however, has been provided for raising or lowering the potential transformer "coupler" tank whenever necessary.

A number of interlocks is provided to prevent operating errors and to protect personnel. For instance, one of the interlocks prevents the opening of the upper door in the disconnecting switch house until the disconnecting switch is opened; this causes the shutter which prevents access to live parts to close. Another interlock prevents operation of any or all disconnecting switches on both sides of the circuit breaker unless the latter is open. This interlock is effective on each disconnecting switch on individual operation as well as on group control. The circuit breaker cannot be closed unless all the disconnecting switches on both sides of the breaker are fully open or completely closed. An interlock also prevents operating any of the line disconnecting switches unless the line cable test switches are open. Conversely, no line cable test switch can be operated until line disconnecting switches have been opened. An interlock also prevents the lowering of any potential transformer coupler tank unless the ground switch and test switch on that phase are closed. An interlock also prevents opening any ground switch or test switch until the potential transformer coupler tank is in the connected position; this is accomplished by means of a system of Cory locks.

### 115,000-Kw. Generator

The generator which is tied into the 132-kv. metal-clad switchgear equipment is a 115,000-kw. single-shaft unit, designated as unit 5. A description of its mechanical details is included in the companion article, "A 115,000-Kw. Turbo-Alternator," which follows. This unit generates at 18,000 volts and with its 120,000-kva. transformer bank constitutes an operating unit without an intervening bus. The generator leads are tapped to supply the 10,000-kva. auxiliary power transformer, and the high voltage and low voltage switchgear units provided for this transformer are tripped by differential relays in case internal trouble develops, so that interference with the generator operation is avoided.

### Auxiliary System

The low voltage side of this 10,000-kva. auxiliary power transformer is connected to the main 2,400-volt station auxiliary bus which can be sectionalized by units, or can be operated as one bus. Reactors are provided between sections of this bus for fault current control. Power for starting the auxiliaries on units 3, 4, or 5, or for emergency operation in case one of the station auxiliary transformers is out of service, is obtained from the auxiliary bus.

The capacity of the auxiliary power transformers

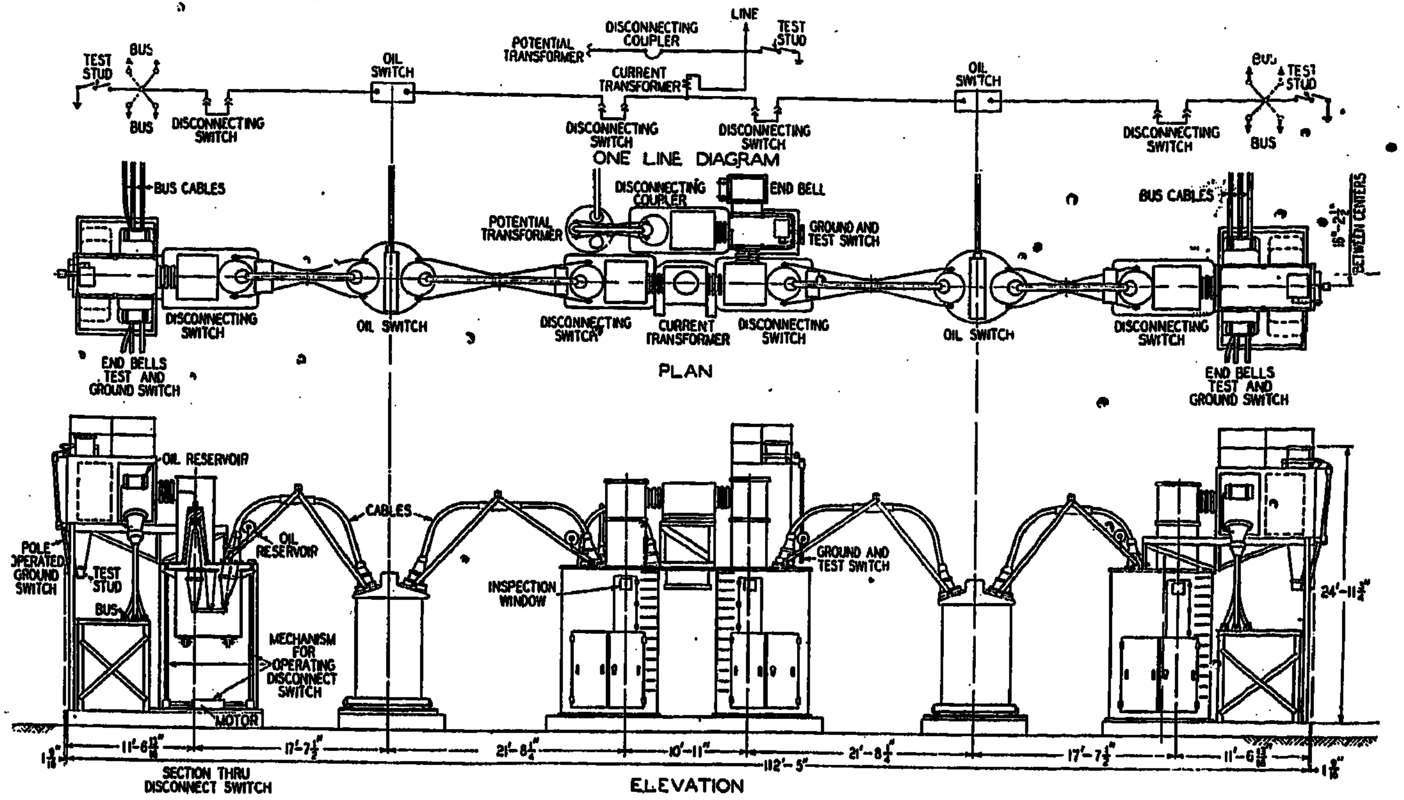

Fig. 2. Layout of one phase of the 132-kv. metal-clad switchgear

in the present installation is 9.4 per cent of the generator capacity, the active and reserve transformer capacity being 7.4 per cent and 2 per cent, respectively. These are selected so as to give under normal demand conditions 20 to 30 per cent unused capacity in each transformer.

GENERATOR FIELD CONTROL

Instead of using generator field rheostat and a common excitation bus, as was provided for the first four units, a main and a pilot exciter have been provided on the shaft of unit 5. On this unit the generator voltage is controlled by means of the main exciter field rheostat, thus resulting in a considerable saving due to the elimination of generator field rheostat losses. In addition, a much more rapid and flexible method of controlling the generator is provided, and in case automatic voltage control is later considered advisable, it can be provided easily at a comparatively small additional cost.

Although the use of a common excitation bus as installed for the first four units provides reserve capacity, it was felt that the expense of reserve excitation was not justified for unit 5 because the latter must be shut down in order to repair either exciter, and because, in addition to the reliability of present-day exciters, the main exciter will operate self-excited, thus making it possible to operate without the pilot exciter.

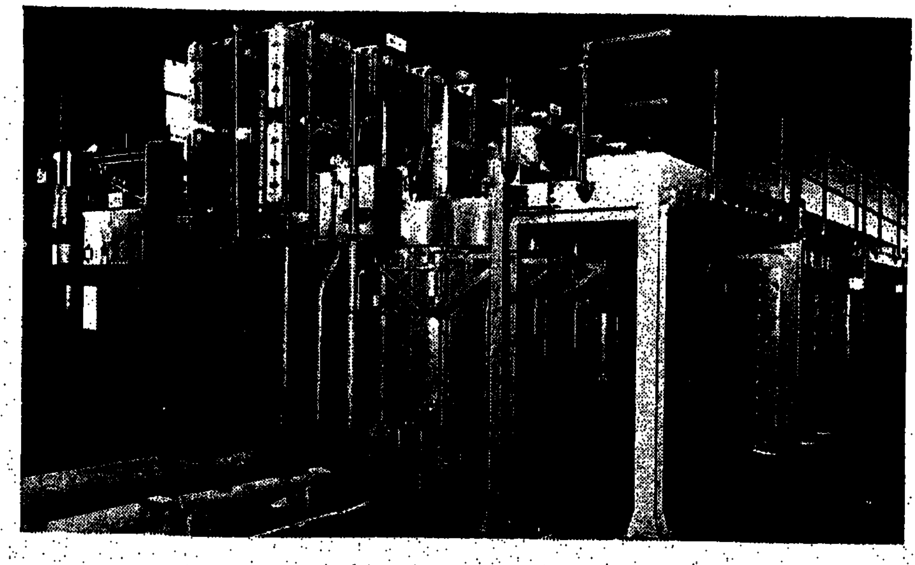

Fig. 3. The 12-kv. metal-clad switchgear used in the second development period

GENERATOR CABLES AND POTHEADS

On the unit 5 installation four single-conductor, 3,000,000-cir. mil, paper-core, 25-kv., paper-insulated, lead-covered cables are used for each phase. These cables extend from the generator to the 120,000-kva. transformer bank in fiber ducts. This 16-duct bank was designed in the form of a square surrounding a large square tile placed in the center of the duct bank to permit air circulation, thus equalizing the internal and external temperatures of the ducts.

Special care in design was used to make the cables carry equal load currents and to avoid injurious sheath voltages. The cable phases in the ducts have been so arranged that the electromagnetic fields surrounding the cables tend to neutralize each other, thus equalizing reactances and avoiding reductions in carrying capacity.

As it was considered more economical to have induced voltages on the cable sheaths than to suffer the losses due to induced sheath currents, cable-sheath insulators were placed at the ends and at about the midpoint of the 550-ft. fiber duct run, thus dividing the cable sheaths into two sections. These two cable-sheath sections are grounded at their midpoints, thus making the induced sheath voltage too small to affect the lead cable sheaths injuriously. Oil filled potheads as well as oil filled joints have been used on the cables for unit 5, as an added safety feature which should insure maximum reliability in service.

On the small power cable the very expensive conduit runs which were needed to protect cable of the ordinary type from mechanical injury have been eliminated and instead, armored cables laid in troughs suspended from the ceiling are used.

As a result the cost of these cable installations has been materially reduced.

### A-C. Car-Mule Drive

One of the recent additions to the coal-handling system at this station is the coal-car mule, which pushes the loaded cars up an incline to the rotary car dumper. The special service requirements of the car-mule drive would normally dictate the use of d-c. motors, but as direct current has not been necessary for the other auxiliaries except for control purposes, it was decided to avoid its use for this device, if possible. Accordingly an a-c. system was developed which is, perhaps, the first of its type used in this country. Solution of the problems of securing large variations in torque with large variations in speed, of obtaining a flexible control system, and of taking the slack out of the hoisting cable to prevent breakage when the load is suddenly applied, have made the use of a-c. motors possible.

The essential feature of this installation is the use of a slow, two-speed, 440-volt, high-torque motor. Coupled directly to the torque motor is the 500-hp., 2,300-volt, wound-rotor, main driving motor. The drive shaft to which the motors are coupled is geared to the car-mule cable hoisting and lowering drum.

The control system of the equipment which pushes a loaded coal car up the incline is complex, but to hoist a car automatically it is only necessary for the operator to move a master control switch to the final point. This closes contactors which put the torque motor on its high speed winding and thus brings the car mule out of the pit at a speed of 150 ft. per min. As the car mule approaches the coal car which has rolled over the hump, a limit switch operates and energizes intermediate circuits which puts the torque motor on its low-speed winding, so that the mule engages the coal car at a speed of 50 ft. per min. This operation also places the main motor on the line with all its starting resistance inserted. After the car has been picked up, another limit switch operates to energize a contactor which accelerates the main motor. This process continues in six steps until the main motor reaches its maximum speed of about 300 ft. per min. As the car approaches the car dumper cradle, the car is slowed down to 150 ft. per min. by inserting automatically all of the main motor resistance, and the torque motor is put on its high-speed winding. If the cradle is properly seated, the car and mule will proceed to the final mule limit; at this point the motors stop automatically and the brakes set. By reversal of the master switch, other motors change the position of the track gates through which the car mule leaves or enters the pit, and the car mule is lowered automatically.

**Fig. 4. Single-line diagram of the Waukegan power station**

Development of the station is illustrated by this diagram, the generating units having been installed in the order 1 to 5. The later auxiliary bus is 2,400 volts with metal-clad switchgear instead of the earlier 480-volt open type bus with connections extending from the oil switches up to the disconnecting switches and then to the overhead bus. Instead of the 12-kv. cell type structure used with the earlier units, later units have 12-kv. metal-clad switchgear with one circuit breaker and two selector switches to connect with both main and reserve buses. In the most recent installation, generator 5, the generator and its transformers are operated as a unit, the switchgear being the 132-kv. metal-clad type

# A 115,000-Kw. Turbo-Alternator

The tendency of large steam turbine design toward single-shaft units has greatly increased the size of generators operating at 1,800 r.p.m. Consequently, the designer has had to solve a number of problems, mechanical and electrical, because of the great axial length of these machines and the large weights involved, particularly in the rotor. A new scheme of rotor ventilation and other features of such an alternator are described in this article.

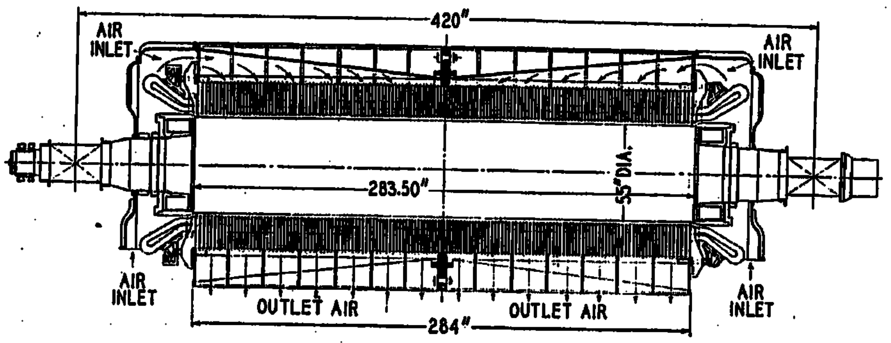

Fig. 4. Sectional view of the generator

IN SEPTEMBER 1931 a 115,000-kw., 0.95-power factor, 121,000-kva., 1,800-r.p.m. generator was put into operation in the Waukegan station of the Public Service Company of Northern Illinois. The station is described in two preceding articles, "Development of the Waukegan Station" and "Waukegan Features New Electrical Designs."

This generator is wound for 18,000 volts, 3,884 amperes, three-phase, 60 cycles. The voltage for this generator was decided after careful study, both from the operating point of view and from considerations of generator design. The whole output of the machine, with the exception of a small part used for the operation of station auxiliaries, is stepped up and all switching done on the high voltage side of the transformers; hence the voltage of this unit did not have to correspond with that of the older units in the station, and it was possible to wind the generator for 18,000 volts in order to obtain the best type of stator winding. The stator winding is placed in 84 open slots, 21 per pole, and connected in two parallel circuits. Two conductors per slot give the simplest form of winding and eliminate practically all danger of insulation breakdown between turns. The coils are made in halves, each conductor being built up of asbestos-covered, varnish-treated strands transposed to eliminate stray currents. At each end of the stator the half coils are connected together with solid clips to form one-turn coils. Since the winding is in two parallel circuits, each conductor carries one-half of the total current output.

The coils are insulated with mica tape, with asphaltum base binder. The insulation is molded in place in such a manner as to secure a dense insulation free from air inclusions. A layer of asbestos tape treated with varnish is placed on the outside of the coils to form a corona sheath. The whole winding was subjected to the standard A.I.E.E. test of 37,000 volts for one minute and there was very little evidence of corona at this voltage. The stator slot and arrangement of conductors are shown in Fig. 2. The projecting ends of the coils, Fig. 3, are supported by lashing to insulated non-magnetic brackets which form ring supports and at the same time avoid closed circuits for stray currents induced by leakage fluxes. In Fig. 4 is shown a sectional view of the generator.

The terminals of the winding are brought out at each side of the end housing so as not to interfere

with the air ducts, and also to render them accessible above the floor line of the unit. Line terminals are brought out on one side and neutrals on the other.

The arrangement of the special compound-filled terminal boxes on the line side of the generator is shown in Fig. 5. These boxes are mounted on the foundation wall directly below the outlet on the generator. Each of the leads is provided with a terminal box in which current transformers for differential protection are mounted. A tap for auxiliary power supply is taken off directly from the main leads as indicated, and a current transformer in the auxiliary tap is provided in the terminal box, together with potential transformers for the machine. The whole arrangement is compact and affords a high degree of insulation. The boxes are filled with soft compound and the potential transformers are oil insulated. The cable potheads on the terminal boxes are oil filled, and lead-covered cables are carried down the side wall of the foundation and protected by a casing extending to the basement floor. This casing is made of aluminum plates bolted together so as to be readily removable.

The stator frame is of welded construction and made in two sections for convenience in handling, the halves being bolted together in a plane normal to the shaft at the center of the machine. An end view of the stator core and yoke with the stator laminations in place is shown in Fig. 6, while Fig. 7 shows the completed winding. The axial length of the laminated core is 281 in. (714 cm.) between end heads. The punchings are clamped between heavy finger plates of non-magnetic cast steel. In stacking the core, the laminations were pressed down by means of hydraulic jacks, as the work progressed. The core punchings are of silicon steel having a loss not to exceed 0.75 watt per lb. at a density of 10,000 c.g.s. lines per sq. cm., 60 cycles. The stator end enclosures are of non-magnetic cast iron. The stator with core and windings complete weighs 350,800 lb. net (159,000 kg.) and was shipped on a special car designed for 400,000 lb. (181,000 kg.) load.

## ROTOR CONSTRUCTION

The construction of the rotor for such a large high speed machine required a great deal of study as the weight of the finished rotor is 228,650 lb. (103,600 kg.). The weight of the rough turned forging was 240,000 lb. (109,000 kg.) and, before rough turning, 264,000 lb. (119,500 kg.). The forging was made from an ingot 108 in. (274 cm.) diameter, weighing approximately 480,000 lb. (218,000 kg.). The finished diameter of the rotor body is 55 in. (139.6 cm.) and the peripheral speed 26,000 ft. per min. (132 m. per sec.). There was considerable discussion with the steel makers as to the possibility of securing a sound forging of such large size and weight in a single piece. Several alternatives were considered, and it was finally decided to make the forging in one piece, but to arrange the design so that if difficulties were encountered the stub shafts could be cut off and stubs bolted to the body, thus making a three-piece construction. Fortunately this was not necessary, as the steel maker produced a single-piece forging which after careful physical tests and inspection by boring proved satisfactory in every respect.

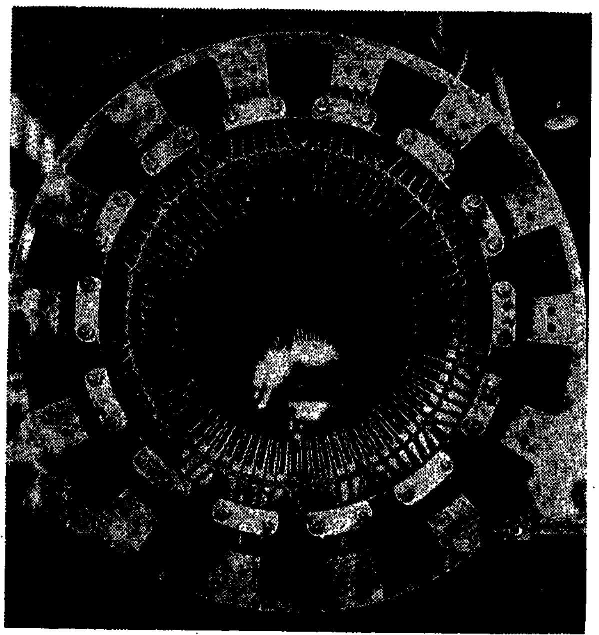

Fig. 6. (Right) Stator with laminations in place

The material in the rotor forging is open-hearth carbon steel, with a small percentage of vanadium thoroughly annealed. The body is approximately 24 ft. (732 cm.) long and the distance between bearing centers 420 in. (1,070 cm.). The rotor body after slotting, also one of the coil retaining rings, is shown in Fig. 8. The rotor is bored throughout its length with an 8-in. (20.3-cm.) hole, the surface of which is polished. The stub shafts are given a smooth finish, the same as on the bearing journals, to remove all tool marks and avoid localized stresses that might start cracks during long continued service. For the same reason all fillets on the rotor and end rings are carefully polished. The rotor end rings are of high tensile strength, non-magnetic, alloy steel in order to reduce stray loss.

In general, the rotor construction does not differ materially from that used for similar large rotors. All insulation is of mica and asbestos. On account of the large diameter of the stub shafts it was not advisable to mount the collector rings between the outboard bearing and the generator, as the rings would have to be of such large diameter that the rubbing speed at the brushes would be too high. The rings were therefore mounted outside the bearings, and leads brought through the shaft.

A new method of ventilation was used on this rotor because on account of its great axial length, the methods heretofore used would not be effective in ventilating the central part. The usual method of rotor ventilation has been to provide longitudinal channels under the coils, into which air can be drawn from each end of the rotor. Holes drilled down through the teeth connect with these channels and when the machine is in operation, air is drawn in from each end through the channels under the rotor coils and thrown out of the holes by centrifugal action. This method works well for rotors of medium length, but for very long machines it is difficult to secure enough inlet duct area under the coils to supply adequate ventilation; and what ventilation is obtained is not uniform along the length of the rotor body.

In the present case, instead of using the centrifugal effect and feeding air in at the bottom of the slots from each end, a method was devised for taking up air out of the air-gap at the circumference of the rotor and utilizing the impact head to force air down through the ventilating holes, returning it to the air-gap. Air from separate ventilating fans is supplied under pressure to the air chambers at each end of the stator and from there passes into 14 inlets (Figs. 3 and 4) spaced equally around the back of the stator punchings From these chambers it blows inward in a radial direction against the rotor, makes a U-turn and passes out radially through the yoke. Thus, air is blown in against the rotor at 14 points and this air is comparatively cool, as it has traveled only a short distance from the inlet. A small portion of the air is by-passed back of the coils in order to cool the part of the stator core behind the teeth, but the greater part blows in against the rotor. There is thus a strong circulation of air through the air-gap at all points throughout the length of the rotor.

The scrubbing action of the surface and the ventilation at the ends of the rotor removes a large part of the heat, but it is also necessary to provide additional ventilation as stated above. The method used in this case is shown in Fig. 9. Radial inlet holes are drilled to within a short distance of the roots of the teeth and outlet holes are drilled at an angle as shown, so as to connect with the former at the bottom. Plugs cut away on the under side are screwed into the tops of the inlet holes as indicated and a short channel is cut in the tooth lip as shown to connect with the slot in the under side of the plug. The plugs are of course locked in position so as to prevent any possibility of turning. When the rotor is rotating, at a peripheral speed in this case of 26,000 ft. per min. (132 m. per sec.), the impact head is sufficient to force air through inlet and outlet holes. Numerous tests made on models showed that the air velocity through the ventilating holes is at least 6,000 to 8,000 ft. per min. (30.5 to 40.7 m. per sec.). Also tests made with an experimental rotor, with and without these ventilating holes but otherwise under exactly similar conditions, showed a decided gain in cooling effect with the ventilating holes. The ventilation does not depend on any centrifugal action, as the centrifugal effects on the air in the inlet and outlet holes are balanced. With this arrangement, as the length of the rotor is increased, the number of ventilating units and the air carrying capacity are also increased in proportion, and a long rotor can be ventilated as effectively as a short one. It might be thought that this method of rotor ventilation would be noisy, but such has not proved to be the case as the rotor makes no more

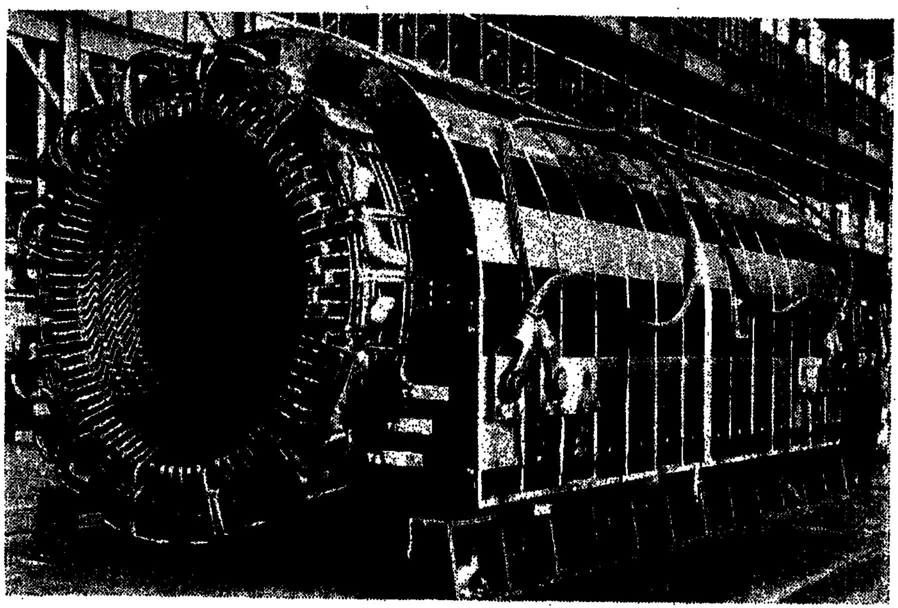

**Fig. 7. Stator with completed winding**

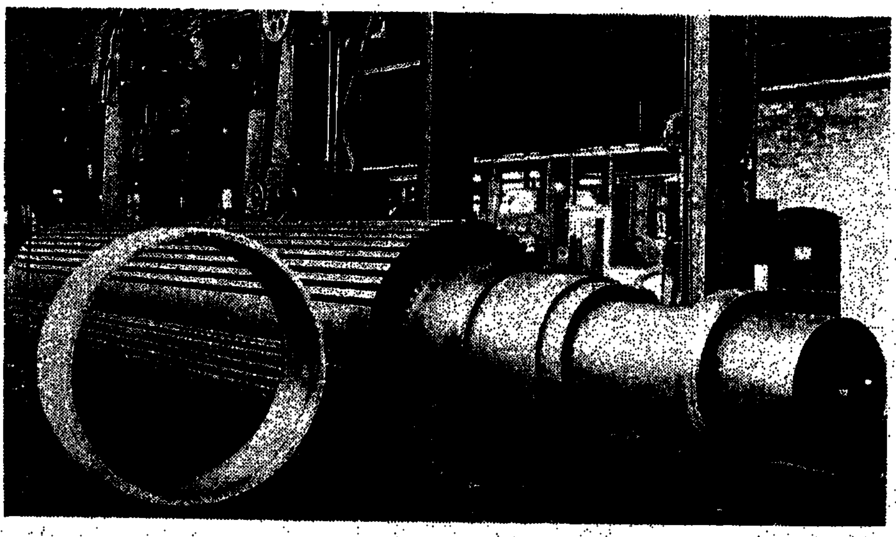

**Fig. 8. Rotor core and shaft after slotting, also one of the coil retaining rings (left)**

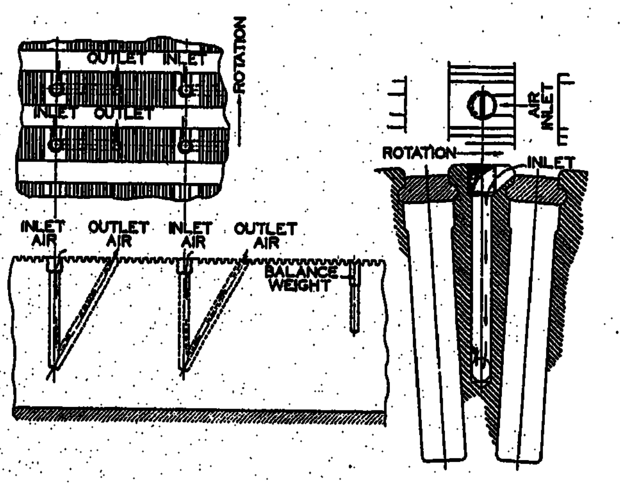

**Fig. 9. Method of securing rotor ventilation (right)**

noise than one provided with the usual centrifugal ventilation.

### AIR SUPPLY

Air is supplied to the generator by four separate motor driven blowers mounted within the foundation space, directly beneath the generator and operating on a closed system. Two of the blowers as installed are shown in Fig. 10, the other two being similarly located on the opposite side of the foundation.

Separate fans were used for several reasons. With a rotor of such large weight and length of body, it was necessary to keep the stub shafts as short as possible and the use of self-contained fans with their air inlets adds considerably to the length of the shaft. Moreover, the large shaft restricts the air inlets to such an extent that self-contained fans could not deliver the amount of air required without excessive inlet velocities and consequent loss in efficiency. Separate fans are more efficient and permit better mechanical design of the rotor, besides being more quiet in operation. Each fan can deliver 50,000 cu. ft. (1,420 cu. m.) of air per min. against 9-in. (22.8-cm.) static pressure. The fans operate at 1,160 r.p.m. and each requires a maximum of 104 hp. To allow ample margin, 150-hp. line-start, squirrel-cage motors are provided. The fans are single inlet type with runners mounted directly on a shaft extension of the motor. All four fan inlets open directly into the chamber under the coolers into which the air is discharged. With the generator delivering 70,000 to 80,000 kw. it is found that two fans furnish sufficient air, and four are operated only under full load conditions. Outlet dampers are provided on each fan so that it can be cut off when not in use. Fig. 11 shows the general arrangement of the blowers in relation to the generator and air coolers.

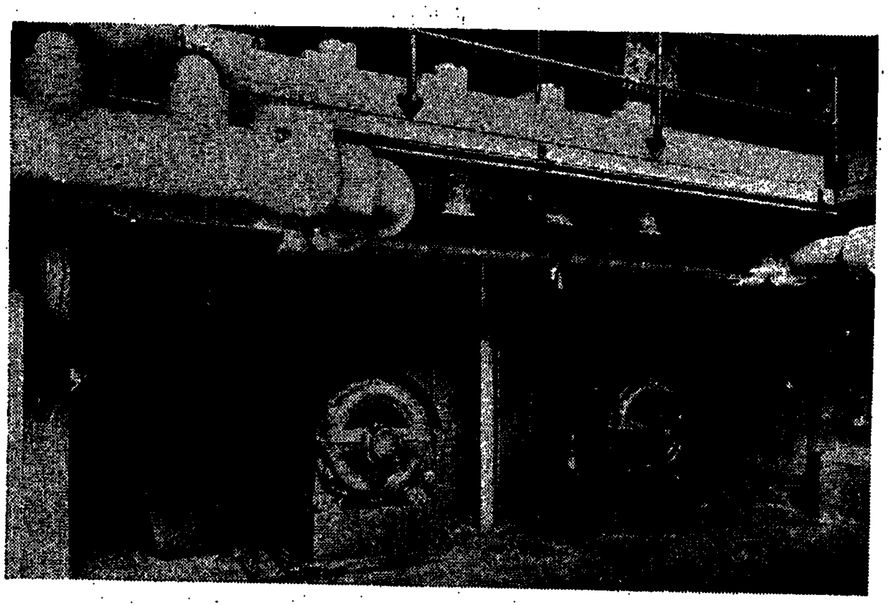

Fig. 10. Two of the four motor driven blowers

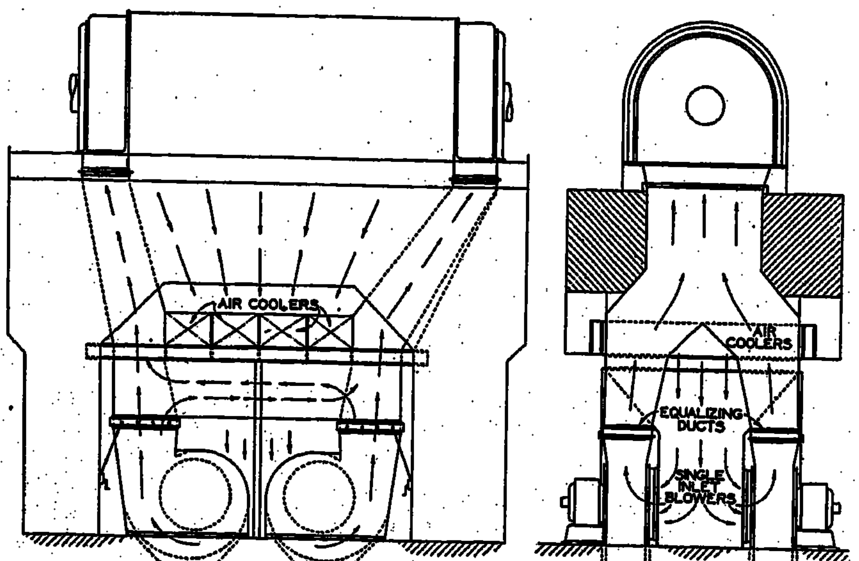

Fig. 11. General arrangement of blowers

For cooling the air, condensate is circulated through a fin type radiator cooler mounted directly under the generator. The cooler is designed to handle 200,000 cu. ft. (5,670 cu. m.) of air per min. with a pressure drop not exceeding $1^1/_2$ in. (3.81 cm.) water. With cooling water temperature not exceeding 80 deg. fahr. (26.6 deg. cent.), it will absorb 6,985,000 B.t.u. per hour and deliver air to the generator inlets at a temperature not exceeding 104 deg. fahr. (40 deg. cent.).

### EXCITATION AND ALTERNATOR CHARACTERISTICS

The rotor is wound for 250-volt excitation and current is supplied by a 350-kw. shunt wound exciter coupled to the turbo-alternator. The main exciter is a two-bearing machine with bearings lubricated from the oil circulating system of the main unit. A pilot exciter of 7.5-kw. output is overhung on the main exciter. This 250-volt machine provides excitation for the fields of the main exciter.

As shown by shop tests, the excitation required to secure rated terminal voltage at no load is approximately 400 amperes, and that required to secure full load current on short circuit is approximately 600 amperes. Regular operation on the station load indicates that the temperature rise of the generator at full load is well within the guarantees of a 60-deg. cent. rise by detector on the stator, and an 85-deg. cent. rise by resistance on the rotor. The estimated efficiency of the generator at rated load, including power required to drive the separate fans, is 98.1 per cent.

# An "Exponential" Slide Rule

AN "EXPONENTIAL" slide rule has been developed to facilitate problems involving the logarithms or antilogarithms of numbers. It differs from the ordinary slide rule of logarithms in two fundamental respects: (1) natural logarithms (to the base $e = 2.71828$) are given, and (2) both the characteristic and mantissa are determined directly in one reading. Logarithms of numbers from 0.00001 to 100,000, and the corresponding antilogarithms are given. As the addition of the characteristic normally would reduce the accuracy of the rule, the scale of logarithms has been split up into five 10-in. sections, thus giving an accuracy comparable with that of the ordinary rule. This exponential slide rule was developed by L. B. Sklar (A '30) 816 North 6th Street, Philadelphia, Pa.

Mr. Sklar states that for determining the logarithms of numbers less than unity, he has discovered a method which may be used both with his new rule and with the ordinary polyphase slide rule. This method involves the use of the *CI* scale in conjunction with the *L* scale, instead of the customary use of the *D* scale with the *L* scale. In dealing with logarithms of numbers less than unity, this method saves time and simplifies the steps involved with a resulting decrease in the possibility of error.

To find, for example, the value of $0.0003^{1.47}$ place the runner of the ordinary slide rule at 3 on the *CI* scale and read the mantissa −0.523 on the *L* scale. The characteristic for numbers less than unity always is equal to the number of zeros, and therefore in this case is −3; the logarithm thus is −3.523. Multiplying this by 1.47 gives −5.18, and the antilogarithm of this number must next be found. Placing the slider at 18 on the *L* scale gives 662 on the *CI* scale. The characteristic −5 indicates that there are five zeros following the decimal point, and the answer is therefore 0.00000662.

It may be seen that if this problem had been solved by the use of the *D* scale, as is customary, rather than the *CI* scale, it would have been necessary to add the step of making the usual subtraction before the correct logarithm is given. A similar subtraction would have been necessary in finding the antilogarithm, and to avoid error pencil-and-paper operations would have been necessary in performing these subtractions. The use of the *CI* scale instead of the *D* scale automatically eliminates the necessity of any subtraction in finding the logarithms of numbers less than unity.

# Motors for 3,000-Volt Multiple Unit Cars

**A new multiple unit car motor incorporating many novel design features was developed for the electrification of the Lackawanna suburban service in New Jersey. So far, these motors have required but little maintenance, and have been remarkably free from flashovers, insulation failures, and mechanical troubles.**

By
**J. C. AYDELOTT**
MEMBER A.I.E.E.

General Electric
Co., Erie, Pa.

ABSENCE OF TROUBLE in commencing service and in maintaining it has characterized the entire suburban electrification program of the Delaware, Lackawanna and Western Railroad. This is especially significant in view of the fact that it is the first multiple unit suburban service in this country employing a d-c. trolley potential of 3,000 volts. A notable lack of motor trouble is one of the factors responsible for the small number of maintenance difficulties experienced.

There are now in service on the Lackawanna railroad, 564 of these motors, the last 141 of which were placed in service on January 25, 1931, when the extension of the electrification to Dover was completed. By June 1, 1932, 13,000,000 car-miles had been operated, with only two train delays, one of nineteen minutes and one of four minutes, chargeable to motor failure. In view of this splendid operating record, it might be interesting to review briefly some of the motor design features that have contributed toward operating reliability.

Characteristics of the motor are shown by the curves of Fig. 1. The motor has a continuous rating of 97 amperes at 1,500 volts, with field shunt at 50 per cent, and a temperature rise not exceeding 105 deg. cent. above ambient. It has a one-hour rating of 130 amperes with a corresponding temperature rise not exceeding 120 deg. cent. above ambient.

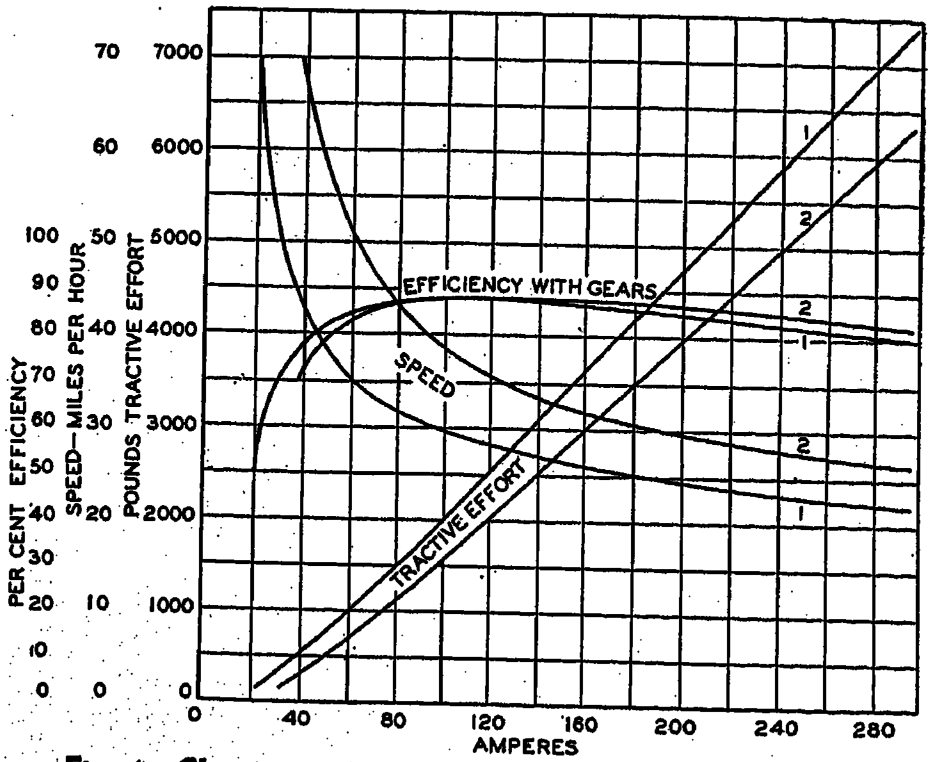

**Fig. 1. Characteristic curves for Lackawanna multiple unit car motors at two different field strengths**

1—Full field strength
2—Reduced field strength

---

Based upon "Motors for 3,000-Volt D-C. Multiple Unit Cars" (No. 32-36) presented at the A.I.E.E. winter convention, New York, N. Y., Jan. 25-29, 1932; subsequently brought up to date by the author.

## MOTOR FLASHOVERS MINIMIZED

So far, the motors have been remarkably free from flashovers, insulation failures, and mechanical troubles. Minimizing of motor flashing is an achievement embracing many features of design. Flashing may be caused by interruptions or disturbances in the voltage applied to the motors; also many things within the motor itself may contribute to flashing, some of these being poor commutator condition, commutator roughness, oil and dirt between commutator bars, flat spots, bouncing brushes, and low motor stability.

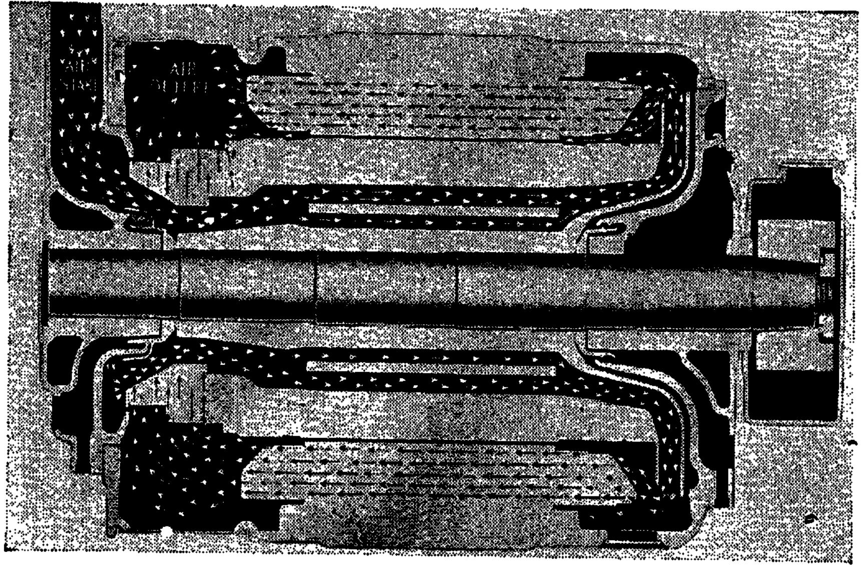

Fig. 2. Cross-section of motor for 3,000-volt d-c. multiple unit cars showing ventilation system

Successful operation of this motor demonstrates the feasibility of a relatively high commutator bar potential. With 281 commutator segments and 1,500 volts applied to the motor terminals, this amounts to 21.3 volts per bar, which is higher than previously used in any 3,000-volt railway motor. Successful operation under these conditions, however, depends upon commutating characteristics that will keep the commutator always in first class condition, and also upon the ability of the motor to withstand frequent wide and sudden variations of trolley voltage on full or weak field with a minimum of "spit" at the brushes.

Good commutation depends first upon keeping the reactance of the armature conductors at a minimum so that the energy involved in the reversal of current in a conductor is low. Besides this, the compensation, which depends upon the quantity of commutating pole flux, must have the required value at all loads. The design of this motor employs a one-turn armature winding. Careful attention was given to the number of slots and the proportions of the slots, air-gap and pole faces. Armature bars are clipped at the back thus permitting a "breaking up of the slots" which has long been a feature of good railway motor design. Nonmagnetic binding wire is used to reduce slot reactance.

It is well known that good commutation usually can be obtained at some one motor load depending upon the adjustment of the commutating field strength; common practise has been to adjust compensation for minimum sparking at some load near the one-hour rating. If the commutating poles were somewhat saturated at this point, the motor would be over-compensated for all lighter loads. To avoid this condition the design of this motor includes ample commutating pole cross-section; as a result, commutation is good from the lightest load to four times the continuous rating. Light loads are mentioned particularly because no sacrifice of commutation at light loads has been made to obtain correct compensation at heavy loads.

To an unusual degree this motor has ability to withstand flashover from voltage interruption. This may be attributed largely to the use of highly responsive commutating poles. Extra turns are wound on the commutating coils; under steady-load conditions the extra magnetomotive force thus produced is consumed in non-magnetic shims at the back of the commutating pole pieces. Thus the commutating pole flux follows very quickly any change in the armature current and tends to maintain correct compensation even under extreme transient conditions. A strong exciting field winding adds to the stability of the motor. The use of an inductive shunt rather than field tapping to obtain weak fields gives any motor a greater ability to withstand flashover from interruption during reduced field operation. In the Lackawanna motor the inductance of the field shunt has been so proportioned that the ability of the motor to withstand flashover on reduced field is superior even to its performance on full field.

## VENTILATION SYSTEM KEEPS MOTORS CLEAN

Motor flashing that might be caused by dirt is avoided by the ventilating scheme developed for this motor. No external blowers are used, but with the system of ventilation adopted the motor operates at all times with its interior either at or slightly above atmospheric pressure. The motors are self-ventilated as shown in Fig. 2. Cooperation of the car builder permitted the ventilating air to be taken from settling chambers over the vestibules to which it is admitted through louvers at each corner of the car roof. A separate duct to each motor extends down through the side and along under the floor of the car to a point over the commutator end bearing where a flexible air connection made of cloth sewed over a coiled wire leads the air to the motor inlet in the commutator end framehead. The flow of air is maintained by a fan on the motor shaft. Air enters the motor under the commutator and passes first through the ducts in the armature; it is then returned by the fan through the field structure of the motor and exhausted at the commutator end. The air outlet opening is covered with an expanded metal screen and a hood, so that foreign material cannot fall or be thrown into the motor.

This method maintains pressure inside all the exposed surfaces of a self-ventilated motor, which means that track dirt, fine snow, or brakeshoe dust cannot enter. It should be noted also that before the ventilating air reaches the commutator chamber of the motor it is filtered, so to speak, through both the armature and the field coils. Furthermore, any carbon dust originating in the commutator chamber is carried directly to the exhaust openings and does not enter any other parts of the motor. Routine inspections have shown these motors to be unusually clean. Surplus oil from the bearings is led through ducts to the outside of the motor and none finds its way inside.

## COMMUTATOR DESIGN

Smooth commutators depend not only upon good commutating characteristics but also upon good mechanical design and construction. The use of four brushholders and the low armature current resulting from the high voltage employed permit the commutator to be compact and strong. The commutator has a diameter of $16\frac{1}{4}$ in. and a brush surface $2\frac{3}{4}$ in. wide. With the cars operating at 70 miles per hr. at least once during every round trip, the motor speed reaches 1,800 r.p.m. At this speed the peripheral velocity at the commutator surface is 7,620 ft. per min.

When the motors were first put into service some brush breakage occurred at high speeds. In a short time, however, the commutators became seasoned so that brush breakage was practically eliminated. The brushholders also play their part in maintaining good commutating conditions. Pressure fingers are of the steel clock-spring type, having low inertia and maintaining their tension permanently; they are centrally located by recessed adjusting sleeves clamped by the first turn of the springs. A non-resilient brush is used to maintain contact with the commutator at high speed. As no abrasive action is necessary to keep the commutator smooth, the brush may be comparatively soft, of low friction coefficient, and may operate with a high contact voltage drop.

Insulation of the motor throughout is in accordance with recognized standards for 3,000-volt railway motors. While the absence of insulation failures in the motors thus far covers a comparatively short period, experience has shown that the same kind of insulation in other 3,000-volt motors lasts indefinitely, failures seldom occurring from any other cause than mechanical damage.

## RATINGS

Ratings of the motors when ventilated as in service are as follows:

| | Volts | Field strength | Shaft hp. | Amperes | R.p.m. | Temperature rise deg. cent. |
|---|---|---|---|---|---|---|
| Continuous | 1,500 | 50% | 181 | 97.0 | 1,055 | 105 |
| One hour | 1,500 | 50% | 255 | 137.0 | 913 | 120 |

Although during the time that it is connected the inductive shunt carries 50 per cent of the current passing through the motor, it has a continuous rating of only 34 amperes. The field shunt is designed with a temperature rise characteristic that, at the r.m.s. current obtained in continuous suburban service, will give a temperature rise approximately equal to the corresponding temperature rise of the traction motor exciting fields. Cold equipments coupled in train with hot equipments will share the load equally.

On short runs the r.m.s. current of the shunt slightly exceeds its rating, reaching a peak value on runs of approximately 3,000 ft., where the calculated r.m.s. value is approximately 37 amperes. However, under these conditions the r.m.s. current of the motor exceeds its continuous rating for 105 deg. cent. rise by resistance. Not only was the present electrification of the Lackawanna considered in studying shunt capacity, but also the possibility of extensions into more mountainous territory involving long uphill runs. These studies indicate that these runs do not require a shunt rating of more than one-third the continuous motor rating for 50 per cent field strength operation; this reduction in shunt rating permits a saving in weight.

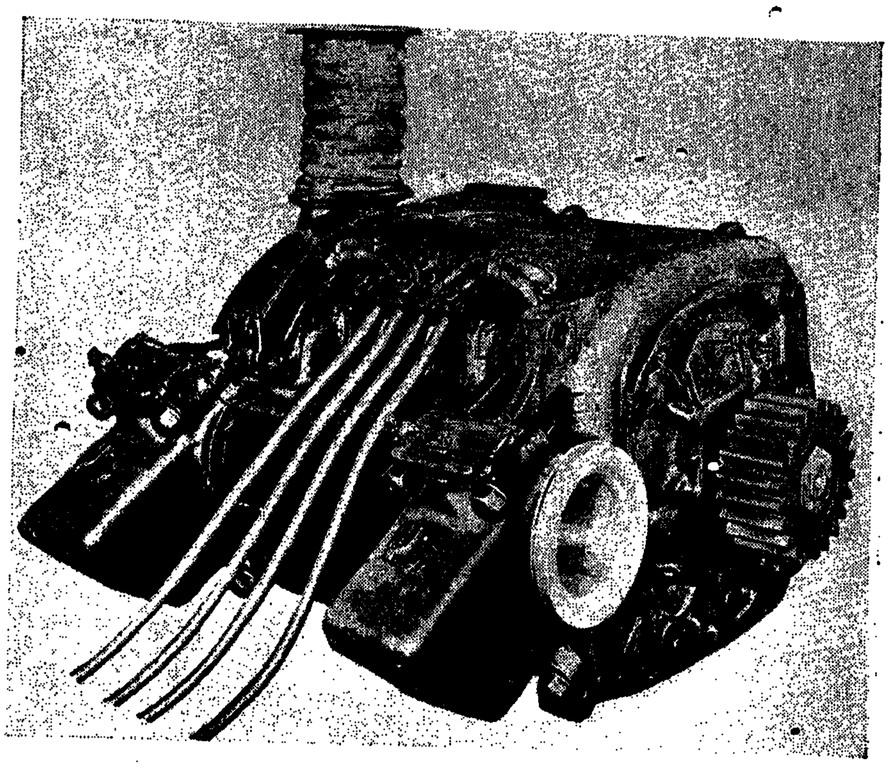

**Fig. 3. Complete motor showing pinion and axle bearings. Note "pants-leg" air duct connector at the upper left**

A view of the complete motor is shown in Fig. 3. Four motors are used on a motor car weighing 81.5 tons loaded; this, together with a trail car weighing 56.5 tons, forms a two-car unit of 138 tons. The motor weighs complete with gear, gear case, and axle lining, 6,850 lb., giving a weight per horsepower of 26.9 lb. The four motors give a capacity for the two-car units of 7.4 hp. per ton. Trains for use in short run commuter service may be made of 2, 4, 6, 8, 10, or 12 cars, half of which in each case are motor cars. A typical six-car train has a free running speed of 67 miles per hr. on level track (Davis friction) and a maximum permissible speed of 70 miles per hr.

Design of the motors permits the use of as high a train accelerating rate as desired, limited only by the weight on drivers and the slipping point of the wheels. Normally, an automatic acceleration of 1.5 miles per hr. per sec. is maintained, corresponding to an adhesion of 12.8 per cent. Acceleration tests have shown an equipment to be capable of reaching 30 miles per hr. in 20 sec. and 47 miles per hr. in 60 sec.

In frequent stop service a four-motor equipment is well loaded by a motor car and trailer unit, the motor temperature approaching the permissible limit for class B insulation of asbestos and mica tape. Experience has shown, however, that for railway motors, class B insulation tightly applied, molded, and hot-drawn will have a longer life if the motors are run hot enough to keep them free from moisture. In long run service the motors will have sufficient excess capacity to permit the handling of additional trailers.

### MECHANICAL DESIGN

Conservative interpretation of experience characterizes every feature of the mechanical design contributing to low maintenance. Stresses in all working parts are low. Both armature and axle bearings are of the sleeve type and embody the constant oil level feature permitting oiling periods to be extended to several times the usual period. There is a layer of babbitt on the wearing surfaces of the bore and flanges of all the bearings. The almost complete absence of hot bearings during the initial stages of the electrification was due not only to design, but to the fact that all of the linings were line reamed after assembly in their respective final positions, and due also to the careful packing of the bearings, oiling, and breaking in.

Operation of the gearing on the motors is quiet, promising long life. Gears are of special heat-treated steel, General Electric Company grade F, 2¼ pitch, with long and short addendum tooth form. To insure correct profile, the gear teeth were ground after treatment. Possibility of the gears giving off ringing notes has been overcome by a non-resonant feature obtained by snapping rings of small cross-section into annular grooves machined in the under side of the rim. These rings have a different period of vibration from that of the gear section, thereby counteracting or destroying the vibrations in the gear. The manner in which the rings are assembled provides an annular pocket for the retention of gear grease; this also has a decided damping effect. After assembly, the rings are welded at the joint to prevent any possibility of their coming loose. Gear cases are of malleable iron with three point support.

During eighteen months of operation the maintenance expense of these motors has been extremely low. The time when commutators will have to be turned down is still in the remote future. Very few motors have been removed from the cars for any purpose. There is every reason to expect continued low maintenance for this first multiple unit suburban electrification employing a d-c. trolley potential of 3,000 volts.

# Refrigeration Improves the Health of Millions

By
WILLIAM H. ADAMS
Detroit, Mich.

ENGINEERING with its benefits enters our homes daily in many ways. Manufacture of artificial ice and mechanical cooling of space have become commonplaces and constitute a major achievement of engineering and science.

But a short generation ago, people lived principally on salt meats, salted and dried fish, dried grains, and dried fruits, and on foods conserved by the early canning and preserving arts, except for a few weeks or months when fresh fruits and vegetables were available from nearby truck farms. The refrigerator freight car and the modern cold-storage warehouse have changed the eating habits of a large part of our people and have brought to the tables of millions of industrial workers articles of food that but recently were the luxuries of the rich.

Early efforts to cool space and goods by the use of natural ice were but partially successful; low temperatures were difficult to obtain and harder to hold uniform. The modern cold-storage warehouse, with temperatures held at any desired level and with but fractional degrees of change, will keep food products in fresh condition for almost an indefinite period.

The consumer has benefited by the lengthened list of foods available, and the health of our people has been improved by this diversity of diet and by the inclusion of vitamin-bearing fruits and vegetables. Instead of the occasional glutted market and then scarcity, the produce of farm, dairy, orchard, and garden now reaches the consumer in orderly and regulated quantities and with a minimum of loss. Lands remote from population centers but well adapted to the production of perishable crops thus may be used with confidence that refrigerated transportation and cold storage at points of consumption or in transit will result in distribution over an adequate time and with the widest possible market.

Our theaters now are cooled and de-humidified mechanically; trains with interior temperatures held at the comfort line ply between our cities and across the desert; office buildings are becoming available with air-conditioning as an added aid to efficiency and comfort. In the most recent field of domestic mechanical refrigeration, more than three million units were in use at the end of 1930, and it is estimated that an additional million were in service by the end of 1931. Presently, at the touch of a switch, our homes will be cooled in summer as readily as they now are warmed in winter.

---

**Editor's Note:** This is the eleventh article in the Engineering Foundation's symposium "Has Man Benefited by Engineering Progress?" Pursuant to the invitation of the Engineering Foundation, the editors will be happy to receive comments, criticisms, or discussions pertaining to this or other articles published in this series.

# Abstracts

## Of Papers to Be Presented at the Summer Convention

INTERPRETIVE abstracts of all technical papers to be presented at the A.I.E.E. summer convention, June 20–24, 1932, are included herewith, excepting only two papers. One of these is published in full on p. 390–1 of this issue; for the other, manuscript had not been received at the time this issue went to press. Members vitally interested and wishing to obtain pamphlet copies may do so by writing to the A.I.E.E. Order Dept., 33 W. 39th Street, New York, N. Y., stating title, author, and number of paper desired. In response to popular demand and within its space limitations ELECTRICAL ENGINEERING subsequently may publish certain of these papers, or technical articles based upon them.

### The Engineering Subjects in the Four-Year College Program of Electrical Engineering

By
A. H. Lovell[1]

THE PRACTISING engineer is vitally concerned with education because the young graduates are trained to meet the specifications of his profession, to join its ranks, and to work beside him in the years to come. He should give advice therefore as to the economic and professional content and interrelation of the programs.

The Society for the Promotion of Engineering Education report of the study of engineering education from 1923 to 1929 gave valuable recommendations as to the preparatory and secondary subjects in the curricula. In view of the developments of the past few years and of immediate future demands, it is time to study the technological portion of the curriculum in electrical engineering. Studies show what some 33 representative schools provide in required and elective electrical divisions and the semester hours required in cognate engineering subjects. Consideration, study, and suggestions are requested from the members of the Institute who are engaged in active practise. (A.I.E.E. paper No. 32-74)

### Educational Aspects of Engineering and Management

By
R. E. Doherty[2]

SURVEYS made by sending questionnaires to organized groups of engineers have established some important facts regarding functional distribution and financial reward. These facts have been interpreted differently, but in order to use them as the basis of any formulation of educational policy, they should be rationalized in terms of their historical setting. Such has been the object of this study. The three predominant facts from these surveys are:

1. More engineering graduates have ultimately gone into primarily administrative positions than have remained in pure technical engineering activity.
2. The former have received greater financial reward than the latter.
3. Excepting a few recent graduates, the former have learned practically all they have known regarding administration after they left college.

The present study indicates that it would be unwise to adopt either the policy of training college students primarily for management or allowing the technical engineering course itself to be sufficient. Both phases of training are necessary and an attempt should be made to emphasize the phase best suited for each individual.

Definite proposals are outlined regarding the type of college training for the professional groups; and an appeal is made that industry recognize the powerful influence which its past salary policy toward technical engineering leadership, as it is unquestionably reflected in these surveys, will have in turning talented minds away from technical engineering. The appeal is not merely to give such engineering its due, but, in industry's own interest, to prevent the problem in the next generation of having a dried up technical engineering leadership. (A.I.E.E. paper No. 32-75)

### Chicago District*

By
L. L. Perry[7]
F. V. Smith[7]

THE LOAD characteristics, generating stations, and transmission lines of the Chicago territory and particularly the power supply of Chicago proper, are outlined in this paper.

The economics of the scheme of supply are discussed from the points of view of interchange energy agreements, comparative incremental fuel costs of generating stations, incremental losses of transmission lines, load schedules, remote metering and load dispatching, economics of 550-lb. to 650-lb. units, automatic frequency regulation, control of voltage, phase angle, and wattless voltamperes.

The reliability of the system is outlined with respect to the design of generators, switchgear, transmission lines and cables, relay protection, methods of operation, and reserve capacity. From the experience gained in the Chicago territory, conclusions are drawn as to the policies of economy and reliability which have been adopted in operating the system. (A.I.E.E. paper No. 32-76)

### Philadelphia Electric Company's System*

By
J. W. Anderson[4]
Herbert Estrada[4]

MAXIMUM system economy is attained when the sum of operating costs plus fixed charges on investment is a minimum. Considerations of reliability usually lead to increased capital investment for sturdier facilities and for spare equipment, and consequently add to the fixed charge burden. Fortunately, however, operating costs are to some extent inversely proportional to fixed charges, and analyses of system performance often will reveal operating savings which can result from judicious use of investment in spare facilities.

[4] Philadelphia Electric Company, Philadelphia, Pa.
[5] Detroit Edison Company, Detroit, Mich.
[6] Edison Electric Illuminating Company of Boston, Mass.
[7] Sargent & Lundy, Inc., Chicago, Ill.

Practises followed on the Philadelphia Electric Company system are discussed in this paper from the standpoint of production facilities in attaining highest system economy consistent with a high degree of service reliability. As the system comprises steam and electric stations of different efficiencies, a large hydroelectric plant, and a major high voltage interconnection, the problems of operating economy are both highly important and complex in character.

The reliability of production facilities of this system is indicated by an analysis of the factors affecting customers' service. In 1931 no interruptions to customer service were caused by the failure of production facilities. Further, the operating economies obtained have resulted in a steady reduction of fuel rate per kw-hr. (A.I.E.E. paper No. 32-73)

## The Detroit Edison Company's System*

By
A. P. Fugill[5]

WITH BUT few exceptions, the requirements for extreme reliability and the economical use of resources in any electric system are diametrically opposed. It is not particularly difficult to design and operate a system to give any practicable degree of reliability of customer service if no consideration need be given to the price the customer must pay. On the other hand, if the service standards were lowered sufficiently, a system could be designed and operated with an over-all economy exceeding present values. The real problem is to obtain the required reliability with the maximum operating economy and the minimum of investment.

Reliability of the service furnished by the Detroit Edison Company is assured: first, by the design and installation of facilities to reduce the probability of outage; and second, by a system layout and operating procedure based on segregation and sectionalization to minimize the effect of any outage. Operating economy is secured: first, by the fundamental design of each new installation for reasonably low production cost; and second, by so allocating the load between generating stations that the more economical machines carry a greater percentage of the total load in so far as the physical location of the load makes this possible. (A.I.E.E. paper No. 32-70)

## The Edison Electric Illuminating Company of Boston's System*

By
R. E. Dillon[6]

IN THE DEVELOPMENT and operation of a successfully managed public utility reliability and economy must be based on the particular conditions inherent to the locality which it serves. As a result, every company's problems must have individual study and no set and fast rules can be established for their solution. However, the policies, practises, and experiences of each are helpful in molding the development of others.

The final plan for the addition of a large block of capacity in generating or distributing facilities is the result of a compromise between those features that seek a minimum of investment outlay, to be obtained by simplicity, and those that urge complications designed to give a high degree of operating flexibility in behalf of reliability. Reliability, it should be pointed out, is not necessarily sacrificed in the plan for less total investment. On some occasions reliability may be assured with smaller total investment by the installation of more spare capacity using simplified equipment at less cost per kw.

On the system of the Edison Electric Illuminating Company of Boston, the occasions of total interruption of service to any large single customer or group of smaller customers due to loss of transmission facilities have been negligible. A decided improvement in operating economy has been secured by generating units, turbines, and boiler equipment. Furthermore, automatic substations together with modern equipment have improved efficiency and reduced labor.

These changes came about in the course of providing for the growth of load. They were attended also with increasing education on the part of the attendants toward efficiency and an increasing vigilance of all forces against losses. (A.I.E.E. paper No. 32-71)

## Oxid Coatings on Aluminum

By
J. D. Edwards[10]
Martin Tosterud[10]
H. K. Work[10]

INTEREST in oxid coatings on aluminum began with the discovery of the metal about 100 years ago, for the chemical attraction of aluminum for oxygen is one of the most important characteristics of the metal. At various times in the history of aluminum, attention, from the scientific standpoint or from the commercial point of view, has been focused on the oxid film. To the scientist, for example, the electrical characteristics of the oxid film have been of great theoretical interest and for many years have been the subject of experimental study and speculation. Important commercial uses of the film in various electrical devices have followed upon the scientific studies.

The remarkable characteristics of the oxid film are discussed in this paper, and a large number of practical uses which can be made of these characteristics are pointed out. A very important characteristic of the film is its impermeability with high protective properties. Also, extensive use of film-coated aluminum has been made in the electrolytic rectifier, and more recently in the electrolytic condenser.

The extensive use of oxid coatings having thicknesses comparable with those of a paint film is a relatively recent development. By a special process films of greater thickness may be formed which have a hardness partaking of the characteristics of corundum and capable of being made of high dielectric strength so that they can be used for purposes of electrical insulation. These thick oxid films also can be colored by absorption of dyes or mineral pigments.

Many commercial uses other than those of the electrical industry may be made of the various types of oxid film. (A.I.E.E. paper No. 32-78)

## Calculation of Inductance and Current Distribution in Low Voltage Connections to Electric Furnaces

By
C. C. Levy[8]

LOW VOLTAGE circuits supplying electric furnaces present special problems in the calculation of inductance and current distribution, in that the conductors employed vary in arrangement and cross-section, and are relatively short. The very large currents carried give rise to reactive drops of greater magnitude than is usually supposed, and a detailed study of the inductance of such circuits therefore is desirable.

Formulas and methods are presented in this paper for the determination of the inductance of relatively short bars with the particular arrangements found in furnace circuits. Fundamental theorems for deriving geometrical mean distances first are established, leading to the well-known formulas for self-inductance and mutual inductance of circular and rectangular sections. Practical applications of these formulas to the problem of calculating the approximate reactive drop in single phase and three phase furnace circuits are worked up in great detail. The same calculations may be used to determine the approximate operating power factor of the furnace. Unequal current distribution in multiple conductors, due to proximity and skin effects, is shown by numerical applications.

The methods presented while not precise are sufficiently accurate for practical purposes and enable the avoiding of unnecessary reactance. (A.I.E.E. paper No. 32-79)

# Electrical Equipment for Precipitation Service

By
H. Speight[8]
V. G. Rydberg[9]

APPLICATION of a strong electrostatic field accompanied by corona discharge to the cleaning of gases was first shown by Hohlfeld in 1824. In 1884 his observations were extended by Sir Oliver Lodge, who continued the work and made a practical installation at a lead smelter in Scotland. In 1905 and 1906 this work was extended by Doctor Cottrell; this extension led to the development of the electrical precipitation process for the separation of solids and liquids from gases. This process is now used in a variety of applications.

For best results, uni-directional current is used, with a negative discharge electrode and positive collecting electrode. The electrical equipment generally employed consists of a specially designed transformer, mechanical rectifier, motor-generator, rectifier motor, switchboard, and accessories. There are, however, many disadvantages to the mechanical rectifier, and a tube type of rectifier has been developed to furnish uni-directional current for meeting the unusual load conditions encountered. This has the following advantages: Less space is required, no surges due to rectification will result in the circuit, the wave form supplied will be regular, the voltage will remain constant, no radio interference will result from the rectifying equipment, polarity is automatically controlled, and operation is very quiet.

The control scheme developed for the tube type of rectifier is relatively simple and is self-protective. The rectifier tube is of rugged construction, and for such tubes an operating life of over 4,000 hr. has been secured. Experience with these installations to date has given the important result that a higher recovery per kw. input is obtained than is secured with mechanical rectification. (A.I.E.E. paper No. 32-77)

# New Applications of Non-Linear Circuits to Relay and Control Problems

By
C. G. Suits[11]

CONNECTIONS of reactors and capacitors in series and in parallel permit obtaining voltampere characteristics which are non-linear and which present interesting possibilities when applied to voltage sensitive and current sensitive relays. With the reactor and capacitor connected in series and properly adjusted, there is a value of increasing voltage for which the current suddenly changes to a high value, and another value of decreasing voltage for which the current suddenly decreases. These characteristics assist in obtaining a relay which is sensitive to small changes in voltage. Similarly, a current sensitive relay can be obtained by the parallel connection of reactor and capacitor.

Based on this principle a voltage relay has been developed which employs a solenoid and armature contactor mechanism energized in parallel with the capacitor of a series non-linear circuit. When used on a source of constant frequency this type of resonant relay may be adjusted to a minimum difference between "pick-up" and "release" of 1/4 per cent and, by change in resistance alone, may be adjusted to a maximum difference of 30 per cent referred to the pick-up value. The maximum power requirement is six watts at twelve voltamperes. The frequency error is of the order of 1 per cent in voltage for a 1 per cent change in frequency.

Using a modification of this same principle, a current sensitive relay has been developed also for which the difference between the pick-up and release values may be adjusted between limits of 3 per cent and 15 per cent. As in the case of the voltage relay, the percentage difference between these values and their magnitude are separately adjustable. The total power input at the resonant current of the current relay is of the order of six watts at 6.5 voltamperes. (A.I.E.E. paper No. 32-85)

# Insulation Coordination of Distribution Transformers

By
E. D. Treanor[12]
W. H. Cooney[12]

AS AN ALTERNATIVE to the use of distribution transformers of present levels of dielectric strength with lightning arresters connected either in the customary manner or having the primary lightning arrester ground interconnected with the grounded neutral of the transformer secondary main, a study of the coordination of insulation of distribution transformers has been carried out.

Test results on distribution transformers designed to meet these requirements of coordinated insulation show that by the use of shields for the high voltage winding and thyrite resistors for the low voltage winding, transformers can be made in which the internal insulation will be protected by flashover of the bushings. The level of insulation chosen and the amount of system protection desired by the use of lightning arresters will determine the economic value of such transformers.

Whatever considerations apply to the discharge of impulses into the secondary circuit must be taken into account, with the knowledge that such transformers have a maintained level of strength which will minimize these discharges. As distribution transformers coordinated at the level of line insulation would be prohibitively expensive, a compromise based on sound past practise seems to present a logical improvement. (A.I.E.E. paper No. 32-80)

# Characteristics of Surge Generators

By
P. L. Bellaschi[13]

THE REQUIREMENTS and limitations of surge generators for transformer testing can be summed up as follows:

When the capacity of the transformer is great, the voltage that can be obtained is in the first place largely determined by the capacity of the surge generator.

If a wave is desired without superimposed oscillations, it is necessary to insert resistance within the generator. The front of the surge then depends on the inductance of the generator and the capacity of the transformer. This is a matter inherent with all surge generator test circuits. Thus, in general, waves of very steep front cannot be obtained with large transformers.

Further, the inserted resistance also limits the voltage by an amount dependent on the proportion of this resistance to the load resistance.

For transformers of low inductance, the length of the wave obtained is determined largely by the capacity of the surge generator. This results in a requirement of large generator capacity if very long waves are to be produced.

If the lead between the transformer and generator is appreciably long, other oscillations will be set up which are highly damped but are appreciable at the generator end. These oscillations occur on the front of the wave only, and will be prominent when measurements are taken at the surge generator. (A.I.E.E. paper No. 32-87)

# The Coordination of Transformer Insulation With Line Insulation

By
V. M. Montsinger[12]
W. M. Dann[13]

## Characteristics of Load Ratio Control Circuits

By
L. F. Blume[12]

THE INFLUENCE of saturation phenomena in series reactors on the circuit performance of load ratio control equipment has been made the subject of the present study. It has been found that unless care is exercised in the design of these reactors, gross distortion may be introduced into the circuit, resulting in obtaining across the reactor voltage peaks which may endanger the insulation, and greatly increase the rupturing duty of the circuit breakers.

Formulas which have been developed show that the proportion of line voltage absorbed by a series reactor subject to magnetic saturation, can be expressed in terms of the reactive constants of which the circuit is composed, and that the voltage is independent of the current or voltage wave form. Curves based upon numerical solutions show that the peak voltage across the reactor may be limited to relatively small values by the following:

1. Designing the reactors for relatively low flux density.
2. Using an air-gap which is at least 1 per cent of the total length of the magnetic circuit.
3. Designing the reactor with a large magnetizing current, so as to avoid excessive voltages when overload currents are flowing.
4. Providing the transformer with a larger number of small percentage steps so that the reactor may be designed for a smaller fraction of circuit voltage. (A.I.E.E. paper No. 32-81.)

## Single-Phase Short-Circuit Torque of a Synchronous Machine

By
C. A. Nickle[11]
C. A. Pierce[14]
M. L. Henderson[11]

THE ANALYSIS of synchronous machines previously published by Doherty and Nickle is extended in this paper to include the calculation of torque due to single phase short circuits. The torque is expressed as the sum of odd and even harmonic series which are simply related to those previously derived for the armature current. The effect of amortisseur windings also is taken into account. As an illustration of the application of the equations, the short-circuit torque is calculated for a 100,000-kva. generator.

The mathematical analysis and general equations are presented under the following divisions:

1. Short-circuit armature current.
2. Short-circuit torque.
3. Decrement factors.
4. Single-phase and three-phase reactances. (A.I.E.E. paper No. 32-72)

## Transient Analysis of A-C. Machinery—II

By
Yu H. Ku[15]

AN EXTENSION to salient pole machines is made in this paper, based upon the author's "Transient Analysis of A-C. Machinery." All of the cases as calculated in "Three-Phase Short-Circuit, Synchronous Machines—V," by R. E. Doherty and C. A. Nickel, A.I.E.E. TRANS., v. 49, 1930, p. 700–14, are recalculated by an exact analysis. It is stated that this analysis checks quite closely the approximate analysis of Doherty and Nickle.

Results are given also for a fictitious machine having essentially the same constants as the slotted rotor machine studied in the author's earlier paper, but with salient pole features. Thus comparisons are made regarding transient phenomena of salient pole and slotted rotor machines of essentially the same character.

The effect of external resistance is calculated for different values and, using the machine of Doherty and Nickle, the effect of external reactance and capacitance is also predicted. In the case of capacitance, self-excitation or negative damping is found to exist for certain critical values. (Pamphlet copies not available.)

## Influence on Commutation of Brush Contact Drop

By
L. R. Ludwig[8]
R. M. Baker[8]

IN DESIGNING electrical commutating machinery, an attempt is made usually to produce during commutation a linear change of current with time. This, however, is rarely achieved, and the current density therefore usually is not constant across the brush surface, nor is the contact drop constant. The contact drop also will change with time in any small area on the brush surface, and therefore the static curve between voltage and current measured at the brush contact cannot be used.

In this article the theory and mechanical nature of a sliding contact, the dimensions of a contact, and transient brush drop are discussed. Evidence was found that the number of contact points varied from 10 to more than 50, and these data made possible a determination of the size of contact point necessary to account for the voltage drop observed. It was found that the successful brush has a very large number of contact points, and thus has points of small area which will heat and cool with sufficient rapidity so that high transient voltages are avoided. (A.I.E.E. paper No. 32-66)

## Wire Communication Aids to Air Transportation

By
H. H. Nance[8]

HISTORY of air transportation within the past few years indicates that continued growth may be expected, particularly as hazards to flying are mitigated and safety and dependability are recognized by the public. The government is continuing the extension of airways, weather reporting, and other services, and air transport companies are progressing in developing transport business. Fast and reliable communication service has proved the backbone of weather and position reporting, and has been a valuable aid in the handling of traffic.

Teletypewriter circuits used for land service have been found particularly suited to meeting the various requirements involving simultaneous communication with many stations at remote distances. Other wire communication services, such as long distance telephone and commercial telegraph, have aided also, particularly in reaching points not served by teletypewriter circuits. It is expected wire communication service will continue to be used extensively in connection with air transportation, and will be of considerable aid in its future development. (A.I.E.E. paper No. 32-82)

## Characteristics of Electromagnetic Radiation From Aircraft in Flight

By
J. C. Coe[16]
T. C. Rives[16]

DURING 75 flights made in the vicinity of Wright Field, Dayton, Ohio, during 1931, data have been collected to determine the intensity of electromagnetic radiation from aircraft in flight.

---

[14] Worcester Polytechnic Institute, Worcester, Mass.

[15] National University of Chekiang, Hangchow, China.

[16] Signal Corps., War Dept., Wright Field, Dayton, Ohio.

The radiation from the airplane was recorded by a field-strength measuring set located in a frame building. Attenuation was found to be a function of altitude and frequency, while absorption is a function of frequency and the time of day. The occurrence of fading is shown to be determined by these factors.

Among the conclusions which may be drawn from these data are that for ground distances of 0.4 mile or less the field strength decreases with altitude; while at 1 mile there is comparatively little change in field strength with altitude; and for ground distances of 4 miles or more the field strength increases with altitude. There was no difference between the night tests and the daylight tests, provided that the same conditions obtained as to power, antenna, frequency, and altitude, except that the distances free from fading were much less by night than by day. The results of various tests in which fading was encountered at distances under 60 miles lead to the conclusion that the absorption undergone by the reflected or refracted ray is independent of the angle or distance traveled by that ray. (A.I.E.E. paper No. 32-83)

## Vertically Cut Sound Records

By
H. A. Frederick[17]
H. C. Harrison[17]

FUNDAMENTAL advances in recording and reproducing sound have been made recently through the use of vertical undulations on a disk. These vertically cut disk sound records possess important advantages over laterally cut records, and their use has permitted both the recorder and reproducer to be greatly improved. Among the changes made are the use of "cathode sputtering" to render the original wax electrically conducting before being electroplated, instead of the previous process of graphiting the wax; and the replacing of the abrasive record of the past with a non-abrasive final record.

The improvements which result are:

1. Noise has been reduced 25 to 30 db.
2. Volume range has been increased from about 25 to 30 db. to about 50 to 60 db.
3. Upper frequency cut-off has been extended nearly an octave to about 9,000 cycles.
4. The playing time for a 12-in. record may be increased from about 4 min. to at least 15 min.
5. The life of the record has been tremendously increased.
6. A more faithful reproduction has been obtained as a result of flatter frequency characteristics and less linear distortion, so that sounds are more distinct, life-like, and clean cut.

The demonstrated results with these records are enhanced by the use of better microphones and much more powerful amplifiers and loud speakers. (A.I.E.E. paper No. 32-84)

## Adequate Wiring of Buildings, an Essential for Good Illumination

By
G. H. Stickney[18]
Walter Sturrock[18]

PROGRESS in securing good illumination in buildings has been seriously impeded within a few years by lack of sufficient wiring capacity, much to the disadvantage of owners and managements. This paper reviews the situation from the point of view of illuminating engineering, in the hope of stimulating interest in the problem, thus promoting wider exemplification of practises which will insure a reasonable prospect of lighting circuits adequate to facilitate proper illumination during the life of a structure.

Fairly definite practises have been established for the lighting of small buildings, and fundamental principles have been established for buildings where the lighting requirements may be more severe. A study of standard illumination levels over the past few years indicates the definite trend toward increased illumination, and the expected continuance of this trend will make inadequate the present wiring of many buildings.

Electrical consumption will doubtless be increased by the number of more or less new lighting applications which are going into use. "Built-in" lighting requiring special construction of walls and ceilings of buildings, or simulated by modified forms of luminaires, is spreading rapidly in this country. Lamps are being used which, in addition to the visible light, supply ultra-violet radiation. Also, consideration must be given to the increased load caused by a variety of devices which are supplied from the lighting circuit.

The quantitative elements of wiring also must be considered, and the existing wiring code should be followed. Specifications which have been prepared should be familiar to all consulting engineers, and subjected to criticism by them. Out of this it is to be hoped there may come generally accepted standards of wiring practise. (A.I.E.E. paper No. 32-86)

## Dynamic Braking of Synchronous Machines

By
C. E. Kilbourne[11]
I. A. Terry[11]

TWO GENERAL electrical methods of quickly stopping synchronous machines are plugging and dynamic braking. Plugging, consisting of reversing the phase rotation of the voltage applied to the armature winding, is subjected to a number of serious objections. Dynamic braking, consisting of short-circuiting the armature through an external resistor and maintaining field excitation, is more desirable and generally will result in quicker stopping.

An analytical treatment of dynamic braking is presented in this paper, and is new to the extent that it treats variable speed short circuits, and presents a method of allowing for saturation. The analysis is carried out both for constant effective excitation, and for variable excitation, and general equations are presented which enable a determination of the time required to stop a synchronous machine.

The agreement of test values with the calculated values is quite good at the point of optimum resistance. This is true of the revolutions to stop as well as of the current-speed and time-speed curves. As the resistance is increased or decreased with respect to the optimum, the agreement is somewhat less satisfactory. (A.I.E.E. paper No. 32-67)

## Induction Motor Versatility—The Nature of Its Applications

By
E. W. Henderson[19]

TODAY the induction motor bids fair to bring about another revolution of ideas as regards its use and capabilities. Heretofore, particularly in respect to the squirrel cage motor, it has been confined to rather restricted fields of application. Its starting characteristics and the need of special starting devices were against it. Now, limited-starting-current motors such as those employing double cage rotors are overcoming these starting objections. The use of these "across-the-line" motors has encouraged the idea of throwing standard motors directly on the line as well as the use of induction motors for applications demanding frequent starting or reversing. Formerly the squirrel cage motor was looked upon as one to be applied only for constant speed service; today there are many applications where the operating range covers wide variations in speed.

The demand for adjustable speed has been met to some extent by the slipring motor and commutator type of motor. There is, how-

---

18. General Electric Company, Nela Park, Cleveland, Ohio.
19. Reliance Electric & Engineering Company, Cleveland, Ohio.

ever, a number of applications of single winding, simple squirrel cage motors, which has been adapted to a great variety of uses. These motors, it is pointed out, may be classified as follows: division I covers the slips of approximately zero to 20 per cent; division II covers slips of from 20 to 70 per cent; and division III covers the range from 70 per cent slip to standstill. In each of these divisions a variety of starting and running characteristics may be secured by proper motor design. Stopping characteristics also are subject to control.

Applications of squirrel cage motors for rapid and oft-repeated reversing or starting duty have been very active lately. For such service the squirrel cage rotor has many advantages over the d-c. armature, due to its lower inertia, and the fact that no vulnerable winding, commutator, brushes, and brush rigging are required. These and other characteristics which may be obtained in the induction motor are constantly widening its field of application. (A.I.E.E. paper No. 32-93)

# Current Propagation in Electric Railway Propulsion Systems

By John Riordan[8]

TRACKS of electric railways, being continuously in contact with the earth, allow current to leak into the earth, the track current thus varying continuously at various points along the length of the track, unlike the currents in other conductors of the propulsion system. This paper aims to present a systematic treatment of current propagation in the tracks with a view to providing a theoretical foundation for the treatment of engineering problems in which the electrical behavior of the tracks as a part of the current-carrying system is important.

Such questions generally involve the impedances of electrified railway propulsion networks of varying degrees of complication and their mutual impedances with other conducting systems. Typical practical problems are the calculation of regulation and efficiency, of short-circuit current magnitude and distribution, of induced voltages in communication circuits exposed to the electrified network, and of the effects upon such quantities of changes in one or more of the network elements. Although the method of treatment set forth is illustrated by certain practical examples, the scope of the paper does not include any detailed development of procedure for the engineering application of the results. The treatment is restricted to systems in which the tracks and other leaky conductors, such as ground wires, may be represented with sufficient accuracy by a single conductor; but it includes track discontinuities due to impedances connected either in series with the tracks or between track and ground.

There are developed the properties of a basic circuit consisting of a parallel conductor of finite length, such as a trolley, connected at its terminals to the track which is continuous and infinite. The track currents and voltages to ground of this circuit are derived and collected conveniently into a single table. The self-impedance of this circuit and mutual impedances with other similar circuits are given. These impedances may be employed in representing the propulsion system in the railway network diagram. The basic circuit may be employed also in the construction of cumulative induction curves for neighboring communication lines. Track discontinuities may be taken into account by superposition upon the basic circuit of properly chosen currents flowing only in track-earth circuits. (A.I.E.E. paper No. 32-92)

# A New High Speed Reactance Relay

By A. R. van C. Warrington[21]

MAINTENANCE of stability on modern interconnected high capacity transmission systems is made considerably easier by the use of relays which not only operate extremely rapidly on line faults, especially three phase short circuits, but refrain from operating on the surges of power which often follow the interruption of the fault current. In this paper a new distance relay is described which, it is stated, seems to go further in the direction of meeting these requirements than anything hitherto described.

The new distance relay operates in the order of one cycle, even on low voltage, and employs reactance as a basis of distance measurement, thereby being free from errors due to the variable resistance of the fault itself. The relay is operated by motor units of the dynamometer type and consequently produces many times the torque per unit of electrical input that could be obtained with the induction disk or plunger type of relay.

The distance measurement is carried out by two reactance ohm-units, one set to operate on faults within a zone reaching nearly to the end of the protected line and the other given a higher setting reaching out well into the neighboring section for which back-up protection is desirable. Faults are distinguished from surge and load conditions by a starting unit which is a very sensitive directional relay having a voltage-restraint which gives it an ohmic characteristic. The design employed for the starting unit provides advantages which can be summarized as follows:

1. Maximum protection against undesirable operation during heavy surges of power between generating sources.
2. Maximum response to fault currents, *i. e.*, maximum directional sensitivity only present when required—at low voltage. This is accomplished without the use of contacts and without excessive burden at any potential, normal or below.
3. Extremely rapid action obtained even at low voltages with sturdy relay parts and with normal travels and contact pressures.

The timing unit consists of a clockwork mechanism controlled by an escapement and operated by means of a d-c. solenoid. The function of the timing unit is to allow tripping of the circuit breaker up to a higher ohmic value and after a suitable time delay if the fault is not near enough to warrant instantaneous tripping; also, to trip after a maximum time interval in case of emergency. (A.I.E.E. paper No. 32-12)

# Operation of Relays From Carrier-Current Coupling Capacitors and Capacitance Transformer Bushings

By J. E. Clem[11] R. E. Cordray[21]

APPLICATION of carrier current communication to transmission lines required the development of coupling capacitors. These coupling capacitors may be used also in combination with transformers to obtain potential from the transmission line. This potential will be suitable for the operation of certain instruments and relays, depending upon burden and accuracy requirements. By the addition of suitable chokes, the coupling capacitors may be used also for carrier current communication. It is the purpose of this paper to describe briefly these coupling capacitors, and to point out means for utilizing them for the purpose of obtaining potential for relaying operation, and to call attention to some applications.

The low voltampere capacity of these potential sources, when it is desired to maintain relatively small phase angle errors, renders them suitable only for supplying relay circuits of low burden. By the use of parallel capacitors, however, the burdens of other relays may be brought within the capacity of these potential sources. Ground directional current relays may be supplied from these sources in certain cases, depending upon the complexity of the relaying for the entire system and the ratio and phase angle errors which may be tolerated. In addition to coupling capacitors, within recent years capacitance transformer bushings have been developed which incorporate a tap for obtaining voltage from the line through the capacitance of the bushings. In general, bushing potential devices are suitable sources for reactance relay potential on voltages of 132 kv. and up, and have been applied successfully at 115 kv. on lines of moderate length. # Application of High Speed Relays

By
G. W. Gerrell[20]

CONSTRUCTION of the Osage hydroelectric plant and its interconnection with the existing system of the Union Electric Light & Power Company of St. Louis, Mo., made desirable a study of the relaying schemes as applied for the 66-kv. and 132-kv. transmission lines.

Stability investigations and operating experience definitely indicated the desirability of high speed relays and high speed oil circuit breakers. On the existing system it was possible in a number of cases to use the old oil circuit breakers, rebuilding them for high speed operation.

In the selection of relays for phase-to-phase and three-phase faults, it appeared that during parallel line operation balanced percentage differential relays of the high speed type would offer the simplest and most efficient solution. An analysis of the individual circuits, however, showed that the application of this type of relay was rather limited, and distance relays of the impedance directional type or reactance directional type were required on some of the lines. These two latter types also were used for protection against phase-to-phase and three-phase faults on single lines. Time delay overcurrent relays were used throughout for back-up protection.

For protection against line-to-ground faults, balanced ground current relays were installed in the majority of cases for parallel lines, instantaneous directional ground overcurrent relays being required in two cases for parallel lines. For protection against line-to-ground faults on single lines, either time delay or instantaneous ground relays were used, most of them being of the directional type. Special means were developed for determining the calibration of the reactance and impedance relays.

To date the performance of the high speed relays as applied to this system has been questionable. In favor of these relays it may be said that the relays and the associated high speed circuit breakers have cleared a large number of faults rapidly and correctly, while in their disfavor several cases of operating trouble have occurred. These indicate that the present types of high speed directional relays probably are not applicable to certain types of systems. Further analysis indicates that there are fundamental defects in the design of certain types of high speed relays. Modifications of this particular type of relay, however, are being made. (A.I.E.E. paper No. 32-11)

# The Boric Acid Fuse

By
A. P. Strom[8]
H. L. Rawlins[8]

RECOGNITION of the part played by gas blasts in interrupting arcs in oil circuit breakers and expulsion fuses has opened new avenues for improvements in these devices. The present paper deals with a new type of fuse in which greatly improved performance is obtained by more effective use of the self-generated gas blast.

In this fuse, a form of construction is used which permits the interruption of the smaller ranges of current within a device that is capable of interrupting also heavy short circuits up to 20,000 amperes or more. A special feature of this design is that the lower ranges of current are transferred automatically to, and interrupted in, a small auxiliary fuse bore. While the construction may be used to advantage with any gas generating material, the present design embodies a compressed boric acid liner which has been found to be much more effective than fiber in extinguishing arcs.

Since boric acid evolves water vapor, a condensable gas, it becomes possible to construct a totally enclosed fuse in which the gas blast is discharged into a surface condenser. With such construction, currents of from 5 to 20,000 amperes at 13,000 volts have been interrupted with an electrode separation of less than six inches, using a relatively small condenser. Currents of more than 20,000 amperes have been interrupted by similar fuses of the open type. This type of fuse readily may be designed for various current and voltage ratings. (A.I.E.E. paper No. 32-65)

# Relay Operation From Bushing Potential Devices

By
P. O. Langguth[8]
V. B. Jones[8]

FIELD EXPERIENCE over the last three years establishes the condenser bushing potential device as a reliable and adequate source of potential for the relaying of high voltage systems. The potential device utilizes the inherent potentiometer characteristics of standard condenser bushings used in high voltage circuit breakers and transformers, and depends for its operation on the charging current through the bushing acting as an electrostatic condenser.

Experience shows that potential devices applied within their burden rating will function properly with over-current-directional relays, voltage relays, and distance relays, in various combinations. It is quite possible that the silicon steel device is not sufficiently accurate for some exceptional relays susceptible to phase angle errors, in which cases tests indicate that the hypernik potential device is satisfactory.

Although not so accurate as the potential transformer, the potential device sometimes is more desirable as a source of relay potential. The phase relation between the line voltage and the relay voltage can be easily varied to suit particular system conditions; furthermore, the potential device gives more effective protection with less relay complication than when the potential transformers are connected to the low voltage bus. This being inherently a self-protecting device, no high voltage fuses and switches are required. The successful operation on many large systems, including relaying, indicates definitely the worth of bushing potential devices and the elimination of high voltage potential transformers. The low cost of these devices and the elimination of high voltage potential transformers justify the bushing potential device where usable.

Performance data including curves and oscillograms are given in this paper to illustrate the functioning of directional and impedance relays when energized by potential devices, and typical installations including results of staged field tests are reviewed. (Pamphlet copies not available.)

# Operating Experience With Supervisory Control on the Reading-Philadelphia Suburban Electrification

By
J. E. Pastoret[23]

ALL SUBSTATIONS and switching stations for the Reading suburban electrification are non-attended and are operated by supervisory control. The supervisory control system provides the dispatcher with the following operating features:

1. Control and indication on all circuit breakers and motor operated trolley sectionalizing switches.
2. When an automatic operation occurs, an alarm bell is sounded, proper indication of the position of the unit is given, and a disagreement lamp indicates which unit has operated.
3. An alarm is sounded and an indication is given if any substation battery voltage reaches a predetermined low value; indication is given also when the battery voltage returns to normal.
4. An alarm is sounded and an indication is given if the temperature of any power transformer on the system reaches a predetermined high value; indication is given also when the temperature returns to a safe operating value.
5. All substation bus differential lockout relays are electrically reset by supervisory control.

Supervisory control was selected on the basis of flexibility, speed with which the system can be cleared up at the time of fault, freedom from error, concentration of operation at one point, elimination of divided responsibility, and economy. Two men maintain the equipment which is installed in 21 stations. There has been no trouble experienced from induction, no faulty operations have been performed,

---

[22] New York Edison Company, New York, N. Y.
[23] Reading Company, Philadelphia, Pa.

no faulty indications given, and not a single train delay has been caused by failure of the supervisory control equipment. Each benefit attributed to the equipment has been realized fully in operation, proving the adequacy of supervisory control for operating an electrified railway. (A.I.E.E. paper No. 32-14)

## Developments in Two-Wire Supervisory Systems

By
J. H. Oliver[21]

SPECIFICATIONS for a supervisory system have been modified only slightly during the last few years, and usually require the following: reliability, low maintenance, high speed, simplicity, flexibility, minimum connecting wires, and good appearance. The requirement of minimum interconnecting wires especially is important when the control is to be extended any distance.

A general summary of supervisory control schemes using a minimum of connecting wires is as follows:

1. The four-wire synchronous selector system in use for several years is recommended for the control and indication of both large and small stations where four wires are available or can be procured at small expense.

2. The audible selector system is recommended for the control and indication of small switching, pumping, or hydroelectric stations where operation is infrequent and only one pair of open construction wires is available.

3. The two-wire code selector system is recommended for the control and indication of stations having 23 circuits or less where line wires are economically limited to a single pair.

4. The two-wire synchronous selector system is recommended for the control and indication of small or large stations where the distance between the stations is not over fifteen miles and where only two wires are available or where the additional cost (where the wires are rented) prohibits the use of the four-wire synchronous system.

5. The code synchronous system is recommended for control and indication where several stations are located in the same general direction and it is desired to operate the stations over a common set of wires.

6. The audible indication equipment is recommended for small switching stations, pumping stations, etc., where it is desired to obtain a periodic check only on the indication of a maximum of eleven circuit conditions over the telephone company system from any telephone station. (A.I.E.E. paper No. 32-13)

## Report on Telemetering, Supervisory Control and Associated Communication Circuits

A SUBCOMMITTEE of two committees of the Institute, namely, the committee on automatic stations, D. W. Taylor,[25] *chairman*, and the committee on instruments and measurements, E. J. Rutan,[22] *chairman*, has prepared a report which tabulates and describes, from the point of view of the operating engineer or user, telemetering and supervisory control systems in use today.

The tabulation in the telemetering and supervisory control section of the report enables the prospective user who has a certain requirement in mind, for example, the telemetering of a-c. kilowatts, to determine immediately the systems available for that purpose. All proved systems in general use are tabulated with their characteristics such as accuracy and speed of indication, enabling the engineer to select the system or a few systems particularly adapted for individual conditions. Each scheme has included with it data supplying the characteristics of the communication circuits suitable for the purpose; for example, the user may determine if the scheme he has selected can be used with a given loop resistance with a metallic circuit, but cannot be used with a grounded or non-metallic circuit. A description of the communication circuit is given covering such problems as the use of one circuit for more than one purpose (telemetering and talking, for example) and data on grounding, crosstalk, induction, etc., are given. While much of the information is not new, the tabulation and correlating of the data with the communication circuit is new, and much work has been done by the subcommittee in preparing the data on this phase of the subject.

## The Torque Balance Telemeter

By
A. J. Johnston[21]

BY MEANS of the torque balance telemeter it is now possible to indicate or record with instrument speed and accuracy, the value of such quantities as watts, amperes, volts, temperature, pressure, and flow. These indications may be made up to distances of 100 miles. The value of direct current which is used as the translating means is well within the limit stipulated by the telephone companies. Also, the telemeter automatically compensates for variation in line wire resistance, auxiliary supply power voltage, and variations in tube characteristics.

The device consists fundamentally of an instrument mirror located on an operating element and deflecting light from a lamp source through suitable lenses and mirrors onto two photoelectric tubes of the gas-filled type. The latter tubes are connected to the grid potential of a pliotron tube which supplies the current to be transmitted to the receiving end of the telemetering system.

The receiver may be any form of indicating or recording d-c. milliammeter. If desired, two or more receivers may be operated in series by one transmitter. Likewise, when it is desired to totalize the values of two or more quantities, the transmitters may be connected in parallel to a single receiver. (A.I.E.E. paper No. 32-88)

## Application and Performance of Automatic Equipment on the American Gas and Electric System

By
Philip Sporn[24]
Basil Lanphier[24]
H. E. Turner[24]

DESCRIPTIONS of the great variety of applications of automatic equipment throughout the system of the American Gas and Electric Company are contained in this paper. Reasons for the installations are given, and operating experiences are presented.

The history of the development in operation of automatic station equipment on this system leads to the following conclusions:

1. The flexibility and adaptability of the automatic station when properly applied can contribute greatly to improvement of service.

2. The reliability of automatic equipment is at least as good as that of the very best type of operator, and in general is better than that of the average operator, provided the equipment is maintained reasonably.

3. The automatic station is the ideal solution for handling operating problems at all isolated and lonely locations.

4. Properly applied automatic stations will not only improve service but will do so at a reduced cost.

5. Automatic practise is not only adaptable to its usual functions on power systems, but has spread successfully to such functions as coal handling, coal combustion, and frequency control. No doubt additional functions will be taken over by automatic equipment. (A.I.E.E. paper No. 32-89)

## Vibration and Fatigue in Electrical Conductors

By
A. E. Davison[28]
J. A. Ingles[28]
V. M. Martinoff[28]

VIBRATION in electrical conductors is discussed in this paper. Stress is placed upon the necessity for the development of some new types of conductor which will, because of their shape or some inherent quality, resist more successfully than standard sections, the tendency to vibrate and the tendency to fail because of resulting fatigue. A number of appliances have been put forward from time to time which tend to reduce the amount of vibration ordinarily observed in a span. They are usually called dampers. However, there has been very little work done in the study of preventives.

[25] United Engineers and Constructors, Inc., Newark, N. J.

[27] Aluminum Company of America, Massena, N. Y.

[28] Hydro-Electric Power Commission of Ontario, Toronto, Canada.

The research described in this paper covers the placing of various cables with special section in flowing water and calibrating the resulting vibrations. Some types of stranded conductor show a material reduction in the tendency to vibrate. Among those showing the greatest reduction are the twisted triangle, the twisted square, and three-strand wire. Experiments in water show from 50 to 90 per cent reduction in the amplitude of vibration, other things being as near equal as possible.

The experiments reported are considered only as directional, although a few practical conductor shapes approximating the twisted triangle have been developed and are now being tested in air. The practical difficulties which will be encountered in the use of conductors of this general type are discussed. (A.I.E.E. paper No. 32-69)

## Transmission Line Vibration Due to Sleet

By
J. P. DenHartog[8]

PHENOMENA of vibration in transmission lines due to the action of a transverse wind are encountered most frequently at moderate wind velocities (about 5 miles per hr.) and are characterized by rather high frequencies (5 to 15 cycles per sec.) and small amplitudes (up to a few cable diameters). This type of vibration is caused by the "Kármán" vortices forming behind the wire and is well understood.

Another type of disturbance has been observed, which seems to occur with sharp winds of above 20 miles per hr. with great amplitudes (20 ft.), slow frequencies (1 cycle per sec. or slower), and mostly associated with sleet formation on the conductors. This phenomenon has been rightly described as caused by the change in shape of the conductor due to the ice coating and by the consequent change in aerodynamic lift.

It is the object of this paper to give an explanation of the effect and to show how the stability in this respect of a transmission line can be calculated from the results of an aerodynamic test where both the drag (wind force in the direction of the wind) and the lift (wind force perpendicular to wind direction) are determined for various angles of attack. The conclusions reached may be summarized as follows:

1. The slow vibrations of ice-coated transmission lines in a heavy wind can be explained as due to a certain aerodynamic instability.
2. The phenomenon is entirely different from, and has no connection with, the rapid vibrations observed in fair weather at moderate wind velocities.
3. It is shown that instability occurs when the slope of the "lift curve" is greater than the amplitude of the "drag curve."
4. It follows from the theory that a change in the span length or in the tension of the cable does not affect the phenomenon.
5. The behavior of a toy called the "aerial toubillion" is shown to afford a simple test by which the stability of various ice-coated sections can be determined. (A.I.E.E. paper No. 32-91)

## Stress-Strain Studies of Transmission Line Conductors

By
G. W. Stickley[27]

RESULTS of tensile stress-strain tests illustrating the actual behavior of various conductors used in bare overhead transmission lines, and the effect upon this behavior of certain factors such as repeated stressing and lay of the cable, are presented in this paper.

Tests show that stress in transmission line conductors is not proportional to strain throughout the range of stress to which the cable may be subjected, and which in some cases is as high as from 50 to 70 per cent of the ultimate strength. Also, the modulus of a cable cannot correctly be assumed the same as that of a single wire or rod because the actual modulus of elasticity the first time that stress was applied in the various tests was lower than that obtained the second time and usually both were less than the theoretical or commonly assumed values.

In composite cables such as ACSR which are composed of aluminum and steel wires, additional phenomena occur which are not found in tests of cable composed of a single material. These are caused essentially by the difference in extension at the elastic limit of the aluminum and steel. The different distribution of the two materials therefore results before and after initial loading.

It was found also that the actual increase in modulus resulting from application of stress depends upon the magnitude of the stress applied, the amount of increase becoming proportionately less as the value of stress was increased. Repeated application of the same stress caused no further increase after the first application. The initial modulus was affected slightly by the diameter of the coil into which the cable had been wrapped for handling. The actual modulus of a cable depended upon the length of lay of the component wires, the longer the lay the more nearly the modulus approached that of a single wire. In the design of a composite cable such as ACSR consideration is given to this effect by stranding the steel ore with the longest practical lay and the aluminum wires with the shortest possible lay, the result then being that the core carries a maximum share, and the aluminum a minimum share, of the total stress in the cable.

Lines have been designed in which, during erection, the conductors were stressed at a certain high load for several minutes, thus giving the cable its permanent modulus and set. The feasibility of doing this work at the mill was investigated but found impractical because subsequent handling of the cable resulted in the loss of much of the effect produced. (A.I.E.E. paper No. 32-68)

## Vibration of Overhead Transmission Lines

By
R. A. Monroe[29]
R. L. Templin[29]

STUDIES of vibration of overhead conductors have been prosecuted vigorously for several years in laboratory and fields. The importance of magnitude and distribution of stresses in multiple-strand conductors led to the development of a unique method for measuring stresses in vibrating conductors in the laboratory under conditions closely simulating field conditions, and numerous schemes for effecting better stress distribution at conductor supports have been investigated. These tests have been facilitated by the development of special machinery. Field work has been conducted on special outdoor spans, and observations have been made also upon operating lines at widely separated locations.

Among the results which have been secured in these studies are the following:

1. Theoretical formulas expressing relationship between frequency, loop length, tension, and weight agree well with field observations. The Relf and Ower formula for frequency is substantially correct as indicated by tests embracing various cable sizes and wind velocities.
2. Any suspended cable, when conditions are favorable, will vibrate as shown by records of frequency and amplitude for aluminum, copper, steel, and composite types. A feasible reduction in tension will not prevent vibration and would be of value chiefly in decreasing the direct stress.
3. A properly designed damper will reduce the amplitude of vibration to an amount which scarcely is visible. A formula by Bate states that input of energy from the wind varies directly as amplitude; therefore, an effective damper is required to absorb only a small amount of energy.
4. The efficiency of various types of dampers has been determined by comparison of the vibration of damped and undamped spans. The Stockbridge damper gave better results than any other type investigated, is simple in design and construction, has no moving parts, and is easy to install even on hot lines. To perfect the design and extend to range of application, this damper has been subjected to extensive tests.
5. Experiments on eccentric cable shapes and cables of different stranding show that a rough exterior surface reduces amplitude but do not indicate that a vibrationless cable can be evolved.
6. Variation in vertical load at a suspension camp has been measured but was found to be relatively small in magnitude.
7. Armor rods are primarily reinforcement, although they reduce the amplitude of vibration approximately from 10 to 20 per cent.
8. Adequate practical protection against damage from vibration of conductors is afforded by proper use of armor rods or dampers. (A.I.E.E. paper No. 32-90)

## Of Institute and Related Activities

## Summer Convention Program Extended

FINAL arrangements for the 48th annual summer convention of the Institute to be held at Cleveland, Ohio, June 20–24, 1932, now have been made by the Cleveland national convention committee. Advance notices have been mailed by this committee, which requests that all interested parties send in the return cards supplied. These include the advance registration card, one for hotel registration, and another for sports. As previously announced, there will be no registration fee for the main convention program.

In connection with the entertainment features of the convention, there will be a charge of $5 per person, payable upon registration, covering all entertainment features except greens fees. The special feature on Thursday, June 23, at Nela Park, and including various field events, dinner, and dancing, is covered by this fee. This feature extends through the afternoon and evening of one day, replacing the usual formal banquet.

### TECHNICAL SESSIONS

In addition to the technical papers as given in the announcement for the summer convention in ELECTRICAL ENGINEERING for May 1932, p. 346–8, the following papers have been added:

CHARACTERISTICS OF SURGE GENERATORS IN RELATION TO THEIR APPLICATION TO THE SURGE TESTING OF TRANSFORMERS, P. L. Bellaschi, Westinghouse Electric & Mfg. Co.

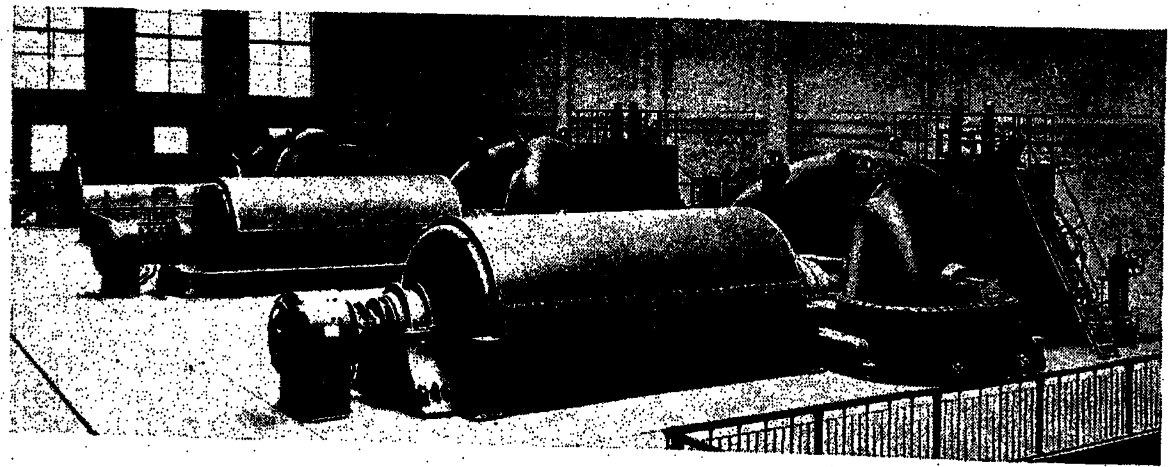
CURRENT PROPAGATION IN ELECTRIC RAILWAY PROPULSION SYSTEMS, John Riordan, American Telephone & Telegraph Co.

REPORT ON TELEMETERING, SUPERVISORY CONTROL AND ASSOCIATED COMMUNICATION CIRCUITS, subcommittee of committee on automatic stations, D. W. Taylor, *chairman*, and committee on instruments and measurements, E. J. Rutan, *chairman*.

The paper by P. L. Bellaschi has been added to the Wednesday morning session on electrical machinery; the paper by John Riordan, to the Thursday morning session on selected subjects and technical committee reports; and the report on telemetering and supervisory control, to the Friday morning session on automatic stations.

One feature of interest in connection with the technical program is that all technical sessions are to be held in the morning, leaving all afternoons free for inspection trips and the various entertainment features.

## Ashtabula Plant to Be Visited During Convention



AMONG the numerous inspection trips arranged for the summer convention of the Institute at Cleveland, Ohio, June 20–24, 1932, is a visit to the Ashtabula steam-electric generating plant of the Cleveland Electric Illuminating Company, the turbine-generator room of which is illustrated above. Three 50,000-kw. units are shown, the first of which was placed in service late in 1930, and the other two in the spring of 1931. These are 1,800-r.p.m. machines generating at 13.2 kv.

## Plans Progressing for Pacific Coast Convention

VANCOUVER, BRITISH COLUMBIA, scene of this year's Pacific Coast convention of the Institute, August 30 to September 2, 1932, has a natural setting difficult to describe adequately. Situated in country striking for its strong contrasts in scenery, it has as well a remarkably temperate climate and excellent facilities for practically every kind of sport and recreation.

In addition to the fine recreational program which the convention committee is preparing, the technical program now practically is completed. Feature topics scheduled for the meeting are:

1. Power generation.
2. Communication.
3. Transportation.

Power generation includes papers on the British Columbia Electric Power System and the Rock Island development on the Columbia River of the Puget Sound Power Company. An interesting discussion on segregation of hydroelectric power costs also is expected. Short-wave radio transmission will be dealt with, and radio links in the British Columbia Telephone Company's system will be described. Railway electrification will be taken up in two papers presenting different angles of the subject. Other topics include corona loss investigations up to 600-kv., zero error current transformers, factory assemblies for substations, metering of symmetrical components, triple harmonic residual effects in transmission systems, and other equally interesting subjects.

With regard to hotel accommodation, very reasonable rates have been arranged as follows with the Hotel Vancouver, convention headquarters:

| | |
|---|---|
| Double bedroom with bath.......... | $6.00 |
| Single bedroom with bath............ | 4.00 |
| Double bedroom without bath....... | 5.00 |
| Single bedroom without bath........ | 3.00 |

Hotel officials are cooperating with the committee and in addition to reserving a number of rooms for the convenience of Institute members, arrangements have been made to insure the comfort of all visitors.

No special travel rates have been arranged, since at the time of the convention the summer rates will be in force. Consideration should be given also to the fact that a holiday spent in British Columbia will be cheaper this year than usual, owing to the present rate of exchange.

## Directors Meet at National Headquarters

The regular meeting of the board of directors of the American Institute of Electrical Engineers was held at Institute headquarters, New York, May 20, 1932.

Present were: *President*—C. E. Skinner, East Pittsburgh, Pa.; *Past-President*—W. S. Lee, Charlotte, N. C.; *Vice-Presidents*—H. P. Charlesworth, New York, N. Y.; W. E. Freeman, Lexington, Ky.; W. B. Kouwenhoven, Baltimore, Md.; I. E. Moultrop, Boston, Mass.; P. H. Patton, Omaha, Neb.; G. C. Shaad, Lawrence, Kans.; *Directors*—L. W. Chubb, East Pittsburgh, Pa.; A. B. Cooper, Toronto, Ont.; J. Allen Johnson, Buffalo, N. Y.; A. E. Knowlton, New York, N. Y.; A. M. MacCutcheon, Cleveland, Ohio; F. W. Peek, Jr., Pittsfield, Mass.; C. E. Stephens, New York, N. Y.; R. H. Tapscott, New York, N. Y.; H. R. Woodrow, New York, N. Y.; *National treasurer*—W. I. Slichter, New York, N. Y.; *Assistant national secretary*—H. H. Henline, New York, N. Y.

Minutes of the meeting of January 27, 1932, were approved.

Resolutions formulated by the executive committee in March, in memory of Past-President Harold B. Smith and National Secretary F. L. Hutchinson, were adopted as resolutions of the board. Tributes to Mr. Hutchinson from Sections and individuals were read.

Minutes of the meeting of the executive committee held March 9, 1932, were presented, and the actions taken at that meeting were ratified. The following actions of the executive committee on applications also were ratified: 1 applicant was elected to the grade of Fellow and 8 applicants to the grade of Member; 4 were transferred to the grade of Member; 233 were elected to the grade of Associate; 91 Students were enrolled.

Reports of the April 13 and May 18 meetings of the board of examiners were presented and the actions taken at those meetings were approved. Upon the recommendation of the board of examiners, 6 applicants were elected to the grade of Member and 13 were transferred to the grade of Member; 163 Associates were elected; 148 Students were enrolled.

The assistant national secretary reported 2,338 members in arrears for dues for the year ended April 30, 1932, and was directed to remove the names from the mailing list after the distribution of the June and July issues of ELECTRICAL ENGINEERING, and to employ the usual methods of collecting the dues and restoring the members to the active membership list. He also reported that on April 30, 1932, 1,018 members (6 Fellows, 85 Members, and 927 Associates) were dropped from the membership list, for non-payment of dues for the fiscal year which ended April 30, 1931.

The board of directors ratified the action of the finance committee in approving, for payment, monthly bills amounting to $22,214.12.

Upon the recommendation of the standards committee, approval was given, as sponsor, of three reports on symbols developed by the A.S.A. sectional committee on scientific and engineering symbols and abbreviations, as follows: "Graphical Symbols Used in Radio," "Graphical Symbols Used for Electric Power and Wiring," and "Graphical Symbols Used for Electric Traction Including Railway Signaling."

The report of the committee on award of institute prizes covering the awards made for the year 1931 was presented, as published elsewhere in this issue.

The annual report of the board of directors for the fiscal year ended April 30, 1932, as prepared under the direction of the assistant national secretary, was considered and approved for presentation at the Annual Meeting of the Institute, Cleveland, June 20.

The national treasurer presented a report covering the fiscal year just closed. Annual reports were received from the general standing committees (exclusive of the technical committees' reports, which will be presented at the summer convention in June and are published elsewhere in this issue). Abstracts of these reports were incorporated in the annual report of the board of directors.

The board by unanimous action appointed H. H. Henline as acting national secretary of the Institute, beginning June 1, 1932.

Representatives were appointed as follows: Bancroft Gherardi to the John Fritz Medal Board of Award, succeeding the late Prof. Harold B. Smith, and H. H. Henline to the Assembly of American Engineering Council, as successor to F. L. Hutchinson.

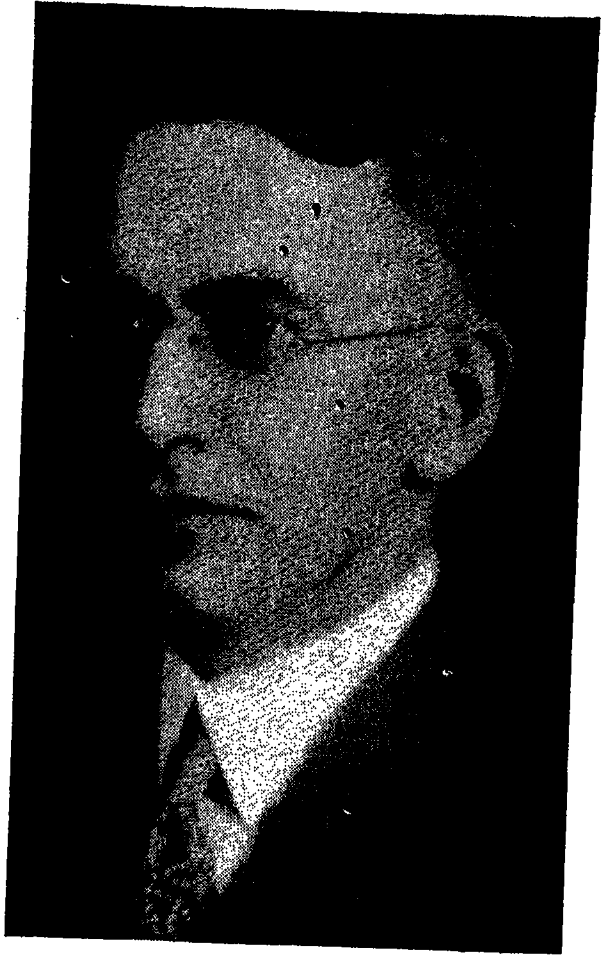
Announcement was made of the appointment of Institute representatives upon a joint committee of the United Engineering Trustees, Inc., and the national societies of civil, mining and metallurgical, mechanical, and electrical engineers to consider the subject of coordination of the various engineering organizations.

It was voted to hold the June meeting of the board of directors in Cleveland, on Wednesday, June 22.

Other matters were discussed, reference to which may be found in this and other issues of ELECTRICAL ENGINEERING.

## H. H. Henline Appointed Acting National Secretary

By unanimous action of the board of directors of the American Institute of Electrical Engineers at its regular meeting held May 20, 1932, Henry Harrison Henline, since 1927 assistant national secretary, became acting national secretary of the Institute, effective June 1. In his new capacity, Mr. Henline takes over the executive duties for twenty years performed by the late F. L. Hutchinson.



H. H. Henline

For many years Mr. Henline has been interested in and actively associated with Institute work and, prior to his affiliation with the national headquarters staff, he made numerous contributions to its published technical works. He was elected to membership in 1919, and has served as chairman of the San Francisco Section (1922–23); faculty counselor for the Student Branch at Stanford University, Calif., (1926); chairman of the Committee on Student Activities for the Pacific District—California, Arizona, Nevada—(1926); and as a member of the Sections committee (1923–27). Since joining the staff January 1, 1927, Mr. Henline has served as the Institute's representative on the American Year Book Advisory Board (1927–32); the American Standards Association (alternate representative 1929–32); Joint Committee on State Engineering Councils (1932–33); and has served on the Institute's Education committee (1929–32). He now becomes a representative of the Institute on the Assembly of the American Engineering Council. While he has been on the headquarters staff, Mr. Henline has participated in many phases of the Institute's work, but has devoted his principal attention to the work of its 60 Sections and 109 Branches.

Mr. Henline was born at Colfax, Ill., March 12, 1889, and after attending local grammar and high schools entered the University of Illinois in 1910, graduating in 1914 with the degree of Bachelor of Science in Electrical Engineering. After serving for a year as instructor in science and mathematics in the Oktaka, Okla., high school and as director of athletics for the Oktaka public schools, he entered the Chicago Central Station Institute of the Commonwealth Edison Company, graduating in 1916 and entering the commercial engineering department of the Illinois Maintenance Company of Chicago.

Joining the faculty of Stanford University in 1917 as an instructor, Mr. Henline later was promoted to assistant professor (1920) and to associate professor (1924) in the department of electrical engineering. In his work of instruction Mr. Henline gave at various times many courses in electrical engineering subjects, and was in charge of the machinery laboratory for five years and in charge of communication engineering for three years. He also was associated with

Dr. Harris J. Ryan in some of the high-voltage research that has made Stanford famous. He is author of a paper on engineering education, a paper on a standard-frequency radio station, and joint author of three papers on subjects relating to high-voltage electric power transmission.

Aside from the affiliations already given, Mr. Henline's organization memberships include the Society for the Promotion of Engineering Education, Institute of Radio Engineers (*Member*), American Association for the Advancement of Science (*Fellow*), Eta Kappa Nu, and Sigmi Xi.

# North Eastern District Holds Eighth Annual Meeting at Providence

In CONNECTION with its eighth annual meeting held May 4–7 at the Providence (R. I.) Biltmore Hotel, the North Eastern District, originator in 1924 of the District meeting idea, successfully conducted another possibly significant experiment in connection with the conduct of such meetings. Largely as an economy measure, but partly also in the interest of promoting better technical sessions, the District committee dispensed with the traditional advance pamphlet copies of the technical papers presented. As for economy, a substantial reduction was achieved in the cost of the meeting to the Institute; as for the effect on technical sessions, they were obviously improved by the more carefully prepared presentations of the various authors.

Accepting frankly the necessity for economy, the District meeting committee sought diligently for ways and means of achieving the desired reduction in meeting expense that would interfere the least with a successful meeting program, and at the same time best serve the average member of the Institute. The committee considered many possibilities, including a reduction in the number of meeting sessions and a reduction in the number of papers presented per session, but finally decided that the best interests of all concerned would be served most effectively by dispensing instead with the traditional publication of pamphlet copies for advance distribution and for circulation at the meeting. Also supporting this decision was the fact that the substance of the more important papers of general interest would be circulated throughout the membership in current issues of Electrical Engineering (in addition to advance publication therein of comprehensive abstracts of all papers), and that the full text and related discussion of all papers so recommended by the technical program committee would be scheduled as usual for inclusion in the September issue of the Transactions.

Further influencing the North Eastern District meeting committee's decision to experiment with the Providence meeting was a strong and growing belief held by a good many active Institute members that the traditional habit of having convention sessions depend primarily upon the presence of pamphlet copies distributed throughout the audience is seriously injuring the quality and general interest value of the sessions. Knowing that the audience facing them either is reading or has read the dissertation about to be presented has caused most authors to give exceedingly sketchy and unfortunately uninteresting oral résumés of their papers. This situation was notably absent at the Providence meeting where nearly every author made an interesting and understandable presentation of his subject. Many, speaking upon the more complicated subjects, simplified and enlivened their presentation by strategic use of lantern slides reproducing diagrams, tabulations, and other illustrations throughtfully coordinated with their oral presentations.

As for the effect upon those attending the sessions, the Providence experiment produced reactions ranging all the way from one extreme to the other, as might be expected. Some few were notably antagonistic to the idea, while a few were equally ardently and unqualifiedly in favor of its wide adoption. Perhaps the principal significance of the experiment lies in the facts that discussion was active, pertinent, and interesting; and that the expressed opinion of many persons attending the various sessions was preponderantly to the effect that the sessions were notably improved. While there was no official expression of opinion in connection with the experiment, the opinion was vigorously expressed to the effect that the full possibility of benefits should be plumbed by a further prosecution of the experiment in connection with other meetings.

## Technical Sessions

The four general technical sessions embraced papers as announced in the April issue of Electrical Engineering: various electrophysical subjects, presided over by Dr. Vannevar Bush; induction and synchronous motor problems, presided over by P. L. Alger; a symposium on traffic control, guided by Prof. H. M. Turner (Yale); and a discussion of the theory involved in electric power transmission, with P. H. Chase presiding. In addition, one entire technical session was given over to the District student convention, with H. L. Wood, senior student from the university of New Hampshire, presiding. Papers presented by students were:

1. The Thyratron Tube for Field Excitation of Electric Generators and Motors, George Andrews, Rhode Island State College.
2. Communication at Five Meters, E. M. Dukat and A. V. Nelson, Yale University.
3. Design and Construction of a Television Receiver, D. W. Mack, University of New Hampshire.
4. Development of a Practical Television Receiver, W. S. Bachman and E. M. Wolf, Cornell University.
5. Electrical Characteristics of a High Voltage Testing Transformer, Messrs. Reiter, Jessel, and Quan, Harvard University.
6. Electricity in Modern Medicine, E. W. Schafer, Massachusetts Institute of Technology.

Sharing honors with the general-interest session devoted to traffic control, the student session enjoyed an attendance in excess of 100, about twice the attendance at the more technical sessions. William S. Lee, past-president of the Institute, was the feature speaker at the student session. The dual theme of his address was directed toward urging student engineers to give attention to economic and sociological subjects in addition to their technical studies, and to encourage them to face the present economic upheaval with the realization that valuable and important opportunities await the aggressive individual and organization.

At the close of the student session the judges reported prize winning papers as follows:

First, D. W. Mack, University of New Hampshire;

Second, E. M. Dukat and A. V. Nelson, Yale University;

Third, E. W. Schafer, Massachusetts Institute of Technology.

## Entertainment

Entertainment features and inspection trips were well planned and executed for both men and women. In addition to local points of historic interest, many enjoyed the trips through the plants of the Gorham Manufacturing Company, and the U. S. Rubber Company, and to the properties of the Narragansett Electric Company and the United Electric Railways Company. Women guests enjoyed a luncheon at the Wannamoisett Country Club, and several small parties took the opportunity to motor to Newport and other nearby points of interest. By courtesy of the Wannamoisett Country Club, members and guests attending the meeting enjoyed golfing privileges.

At an informal bridge party held Wednesday evening, President Skinner rather unexpectedly found himself in the rôle of a travel lecturer. Extemporaneously he took his highly attentive audience on a most interesting movie-monologue trip along the route that he recently had followed through Mexico and into Yucatan. The social climax of the District meeting came Thursday evening with the annual banquet and dance. There again Past-President William S. Lee delivered one of his inimitable discourses on matters non-technical, including poetry.

The Providence District meeting was handled under the very active generalship of District Vice-President I. E. Moultrop of Boston, who served as chairman of the District meeting committee. With Mr. Moultrop on that committee were A. C. Stevens, Schenectady, District secretary-treasurer; C. W. Henderson, chairman of the Syracuse Section; O. W. Briden, secretary of the Providence Section; R. W. Graham, chairman of the Niagara-Frontier Section; W. S. Maddocks, chairman of the Providence Section; J. P. McCann, chairman Worcester Section; R. G. Warner, chairman Connecticut Section; and F. C. Young, chairman Rochester Section.

Under the active, driving leadership of Vice-President Moultrop and Chairman Maddocks of the local committee, the various Providence sessions were conducted rigidly on the time schedule given in the program. When discussion lagged below a satisfactory minimum it frequently was stimulated and when it began to exceed the bounds of the program schedule it was promptly called to a halt. Punctuality was the keynote of many of Vice-President Moultrop's several and pertinent comments, and it paid its dividend in the conduct of the sessions.

As chairman of the local committee, William S. Maddocks carried the major load of work in connection with the Providence meeting. Associated with Mr. Maddocks on that committee were O. W. Briden, in charge of hotels and registration; R. W. Herrick, in charge of entertainment features; Mrs. R. W. Herrick, in charge of women's entertainment; J. W. Keeney, in charge of finance; L. P. Kenneally, in charge of publicity; J. C. B. Washburn, in charge of inspection trips.

In spite of the highly specialized character of several of the sessions, a total of 252 persons attended the meeting according to the official registration (registration fee $1; 50 cents for students). These were grouped as follows:

| | |
|---|---|
| Members | 134 |
| Registered guests | 33 |
| Women | 20 |
| Students | 60 |
| Student guests | 5 |
| Total | 252 |

# 1932 Lamme Medal Nominations Due Nov. 1

SPECIAL attention is directed to the fact that the names of Institute members who are considered eligible for the Lamme Medal, to be awarded in the fall of 1932, may be submitted by any member in accordance with Section 1 of Article VI of the By-laws of the Lamme Medal committee, as quoted in the following:

> The committee shall cause to be published in one or more issues of ELECTRICAL ENGINEERING, or of its successors, each year, preferably including the June issue, a statement regarding the "Lamme Medal" and an invitation for any member to present to the national secretary of the Institute by November 1, the name of a member as a nominee for the medal, accompanied by a statement of his "meritorious achievement" and the names of at least three engineers of standing who are familiar with the achievement.

Each nomination should give concisely the specific grounds upon which the award is proposed, and also a complete detailed statement of the achievements of the nominee, to enable the committee to determine its significance as compared with the achievements of other nominees. If the work of the nominee has been of a somewhat general character in cooperation with others, specific information should be given regarding his individual contributions. Names of endorsers should be given as specified above.

The Lamme Medal, founded as a result of a bequest of the late Benjamin Garver Lamme, chief engineer of the Westinghouse Electric and Manufacturing Company (deceased July 8, 1924), provides for the annual award by the Institute of a gold medal—together with bronze replica thereof—to a member of the A.I.E.E. "who has shown meritorious achievement in the development of electrical apparatus or machinery"; and for the award of two such medals in some years if the accumulation of funds warrants.

The fourth (1931) Lamme Medal has been awarded to Giuseppe Faccioli (F'12) consulting engineer (retired), General Electric Company, Pittsfield, Mass., "for his contributions to the development and standardization of high-voltage oil-filled bushings, capacitors, lightning arresters, and numerous features in high voltage transformers and power transmission." Presentation will be made during the summer convention at Cleveland, Ohio, June 20–24, 1932.

# Electrical Congress to Meet at Paris, July 4-12

On the occasion of the 50th anniversary of the first International Congress of Electricity, the Société Francaise des Electriciens, the Société Francaise de Physique, the Comité Electrotechnique Francais, and the Union des Syndicats de l'Electricité are organizing, under the auspices of the Commission Electrotechnique Internationale an "International Congress of Electricity," which will convene in Paris, Monday, July 4, 1932. The Congress is open to all persons who wish to participate either in a personal or official capacity.

All those wishing to join must advise the head office of the Congress at 134, Boulevard Haussmann, Paris, before June 15, and must remit at the same time one of the following sums:

1. Those who make a contribution of at least 1,000 French francs will be registered as *benefactor members.*
2. Those who pay a membership fee of 250 French francs will be registered as *subscribing members.*
3. Those who belong to the families of Congress members and who pay a membership fee of 50 French francs will be registered as *related members.*

All payments must be drawn to the order of the Société Francaise des Electriciens, who is responsible for the treasury department.

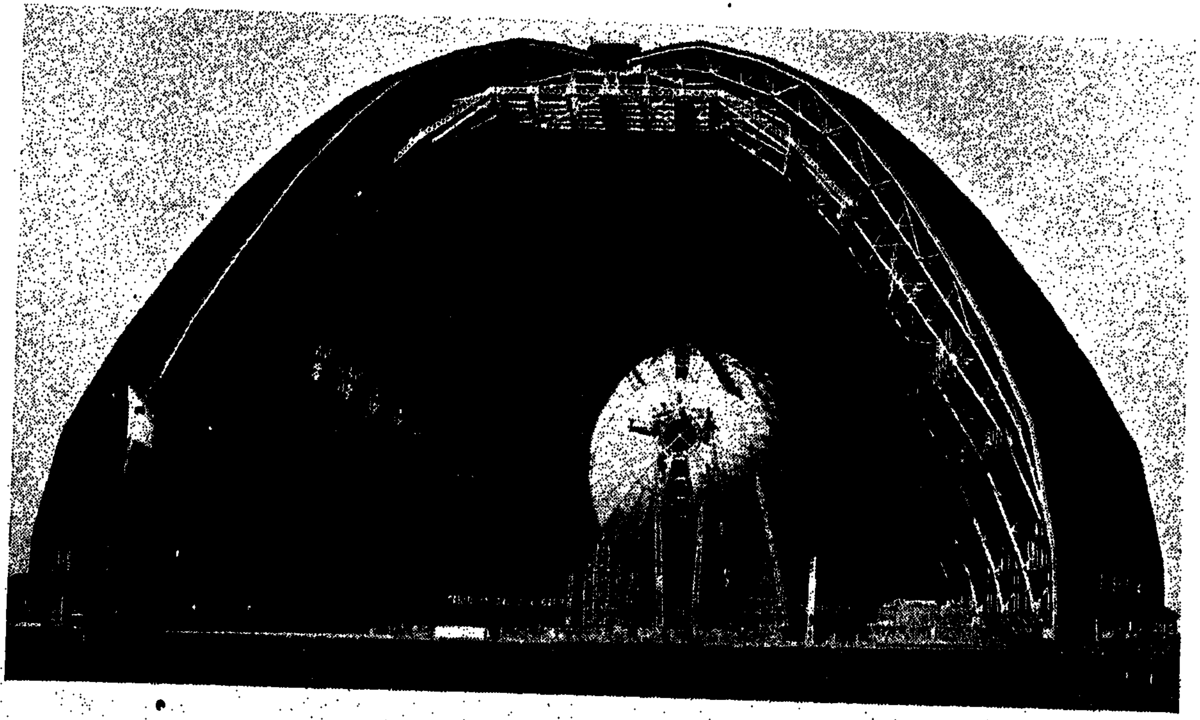
Statements of the work of the Congress will be published in French, and will comprise the text of reports and papers and the reproduction, as exact as possible, of discussions. The transactions will be collected together in several volumes, and in due course interested parties will be advised of the distribution of the work of the thirteen Sections within these different volumes.

Whether or not they attend in person, Benefactor members will be entitled to receive free of charge the entire collection of transactions and, if desired, may take advantage of a discount of 25 per cent on the normal selling price for the purchase of supplementary volumes. Similarly, Subscribing members will be entitled to receive free of charge the volume or volumes containing the transactions of any one Section and can purchase, with a reduction of 25 per cent on the normal selling price, all or part of other volumes containing the transactions.

All persons particularly interested and desiring further information should at once

---

# Goodyear Zeppelin Dock—On Convention Program



CONSIDERABLE popular interest has been evidenced in the inspection trip to Akron, Ohio, which is to take place during the coming summer convention of the Institute in Cleveland, June 20–24, 1932. During this trip a visit will be made to the hangars of the Goodyear Zeppelin Corporation, where the ZR-5 is in process of construction. The ZR-5 is still larger than its sister ship the giant dirigible "Akron," completed there last year. This trip will include also tours of any one of the three large rubber manufacturing plants in Akron; and following a supper at the Mayflower Hotel, the Barberton plant and laboratory of the Ohio Insulator Company will be visited. The outdoor laboratories of this company provide facilities for testing up to 1,000,000 volts, and insure an exhibition which will be instructive and interesting to both the engineers and women guests.

correspond directly with Dr. Harold Pender, Dean, Moore School of Electrical Engineering, University of Pennsylvania, Philadelphia, Pa.

Technical activities are divided into thirteen Sections as follows:

1. Electrical and magnetic science. General theories. Insulators. Conductors. Radioactivity. Magnetic bodies.
2. Electrical measurements: (a) Units and standards; absolute electrical measures. (b) Laboratory measurements; industrial measurements and experiments with machines.
3. Production and transformation of electrical energy.
4. Transmission and distribution of electrical energy.
5. Electrical traction. Mechanical applications.
6. Electric lighting. Photometry.
7. Electrochemistry. Electrometallurgy. Batteries and accumulators.
8. Telecommunications by wire (distant communications by wire).
9. High frequency current phenomena. (a) Radioelectricity. (b) Radio communications.
10. Radiobiology. Electrobiology.
11. Atmospheric electricity. Terrestrial magnetism.
12. Various applications of electricity.
13. Teaching and history of electricity.

# Institute Prize Awards Announced for 1931 Papers

FOUR national prizes for papers presented during the calendar year 1931 have been announced by the committee on award of Institute prizes, which consists of W. H. Harrison (F'31) chairman, L. W. Chubb (F'21), A. E. Knowlton (F'30) and E. B. Meyer (F'27). These prizes in each case consist of $100 in cash and a suitable certificate; in cases of joint authorship the cash is divided. Personal presentation of the prizes will take place at the opening session of the Institute's summer convention at Cleveland, Ohio, June 20–24, 1932.

District prizes as announced by seven Districts include fifteen awards of $25 each, together with appropriate certificates. As in the case of the national prizes, where there is a joint authorship the cash awards are divided.

## NATIONAL PRIZES

### BEST PAPERS

Prize for best paper in engineering practise, awarded jointly to authors of papers in symposium on coordination of power and telephone plant, composed of four parts as follows: "Trends in Telephone and Power Practise as Affecting Coordination" by W. H. Harrison (F'31) and A. E. Silver (F'26); "Status of Joint Development and Research on Noise Frequency Induction" by H. L. Wills (A'30) and O. B. Blackwell (F'17); "Status of Joint Development and Research on Low-Frequency Induction" by R. N. Conwell (F'31) and H. S. Warren (F'13); and "Status of Cooperative Work on Joint Use of Poles" by J. C. Martin (A'12) and H. L. Huber (M'23). This symposium was presented at the winter convention, New York, January 26–30, 1931.

Honorable mention was made of the following papers: "Synchronous Motor With Phase-Connected Damper Winding for High-Torque Loads" by M. A. Hyde, Jr. (A'27), presented at the winter convention, New York, January 26–30, 1931; and "Economics of High Voltage Cable" by D. W. Roper (F'14) presented at summer convention, Asheville, N. C., June 22–26, 1931.

Prize for best paper in theory and research, awarded to L. V. Bewley (A'27) for his paper "Transient Oscillations in Distributed Circuits With Special Reference to Transformer Windings" presented at summer convention, Asheville, N. C., June 22–26, 1931.

Honorable mention was made of the following papers: "Calculation of Synchronous Machine Constants—Reactances and Time Constants Affecting Transient Characteristics" by L. A. Kilgore (A'29) presented at the summer convention, Asheville, N. C., June 22–26, 1931; "Submarine Cable Telegraphy: Influence of Interference" by J. W. Milnor (F'30) presented at the winter convention, New York, January 26–30, 1931; and "An Experimental Lightning Protector for Insulators" by J. J. Torok (A'27) presented at the winter convention, New York, January 26–30, 1931.

No prize was awarded in the field of public relations and education.

### INITIAL PAPER

Prize for initial paper awarded to Ernst Weber (A'31) for his paper "Field Transients in Magnetic Systems" presented at the summer convention, Asheville, N. C., June 22–26, 1931.

Honorable mention was made of the following papers: "Extinction of Short A-C. Arcs" by T. E. Browne, Jr. (A'31) presented at the summer convention, Asheville, N. C., June 22–26, 1931; "The San Francisco-Los Angeles Section of the Pacific Coast Telephone Cable Network" by E. M. Calderwood (M'24) and D. F. Smith (A'31) presented at Pacific Coast convention, Lake Tahoe, Calif., August 25–28, 1931, and "Temperatures in Electric Power Cables Under Variable Loading" by E. A. Church (A'29) presented at the North Eastern District meeting, Rochester, N. Y., April 29–May 2, 1931.

### BRANCH PAPER

Prize for branch paper awarded to J. R. Batcheller for his paper "Abridged Method of Testing Welds" presented at the joint meeting of the Portland Section and Oregon State College Branch, May 23, 1931.

Honorable mention was made of the following papers: "Accumulation of High-Potential Static Charges on Transmission Lines During Sand Storms" by C. E. Houston, presented at the South West District Meeting, Kansas City, Mo., October 22–24, 1931; and "Influence of Preservatives on the Dielectric Strength of Wood" by C. B. Parsons and M. H. Tipton, presented at a joint meeting of the Portland Section and Oregon State College Branch, May 23, 1931, and at the Pacific Coast convention, Lake Tahoe, Calif., August 25–28, 1931.

## DISTRICT PRIZES

### DISTRICT No. 1

Prize for best paper awarded to P. H. Moon (M'29) for his paper "The Theory of Thermal Breakdown of Solid Dielectrics" presented at the North Eastern District meeting, Rochester, N. Y., April 29–May 2, 1931.

Prize for initial paper awarded to E. A. Church (A'29) for his paper "Temperatures in Electric Power Cables Under Variable Loading" presented at the North Eastern District meeting, Rochester, N. Y., April 29–May 2, 1931.

Prize for Branch paper awarded jointly to D. C. Robinson and R. W. Stone for their paper "A Study of Torque-Time and Slip-Time Relations of an Induction Motor Flywheel Set Operating on a Mine Hoist" presented at the North Eastern District meeting, Rochester, N. Y., April 29–May 2, 1931.

Honorable mention was made of the paper "The Theory of the Capacitance Potentiometer" by A. W. Moon and W. B. Brainard, presented at the North Eastern District meeting, Rochester, N. Y., April 29–May 2, 1931.

### DISTRICT No. 2

Prize for best paper awarded to W. P. Taylor (A'26) for his paper "Locating Power Cable Faults by Means of a Constant-Current Transformer With Short-Circuiting Switch" presented at a meeting of the Baltimore Section, May 15, 1931.

Prize for initial paper awarded to W. P. Taylor (A'26) for his paper "Locating Power Cable Faults by Means of a Constant-Current Transformer With Short-Circuiting Switch" presented at a meeting of the Baltimore Section, May 15, 1931.

### DISTRICT No. 6

Prize for Branch paper awarded jointly to C. A. Church and N. R. Damon for their paper "New Ideas for High-Voltage Circuit Breakers" presented at a joint meeting of the Denver Section and University of Colorado Branch, April 24, 1931.

### DISTRICT No. 7

Prize for Branch paper awarded to C. E. Houston (A'32) for "Accumulation of High-Potential Static Charges on Transmission Lines During Sand Storms" presented at the South West District meeting, Kansas City, Mo., October 22–24, 1931.

### DISTRICT No. 8

Prize for best paper awarded to W. S. Peterson (M'29) for his paper "Calculation of Dynamic Power Limit of Transmission System During Three-Phase Faults" presented at a meeting of the Los Angeles Section, February 17, 1931.

Prize for initial paper awarded to V. A. Hoover (A'32) for his paper "Correlation of Induction Motor Design Factors" presented at the Pacific Coast convention, Lake Tahoe, Calif., August 25–28, 1931.

Prize for Branch paper awarded to E. W. Palmrose for his paper "Vacuum Tube Voltage Regulators" presented at Pacific Coast convention, Lake Tahoe, Calif., August 25–28, 1931.

### DISTRICT No. 9

Prize for best paper awarded to A. Shipek (M'29) for his paper "Analysis of Distribution Substation Costs" presented at a meeting of the Seattle Section, May 19, 1931.

Prize for initial paper awarded to J. L. Watson (A'17) and R. C. Gleeson for their paper "A Special Application of the Potentiometer Principle" presented at a meeting of the Portland Section, December 8, 1931.

Prize for Branch paper awarded to J. R. Batcheller for his paper "Abridged Method of Testing Welds" presented at a joint meeting of the Portland Section and Oregon State College Branch, May 23, 1931.

### DISTRICT No. 10

Prize for best paper awarded to G. L. Lillie (A'21) for his paper "Factors in Design of 115-230-Volt Distribution in a Modern Residential District" presented at a meeting of the Toronto Section, March 27, 1931.

Prize for initial paper awarded to G. L. Lillie (A'21) for his paper "Factors in Design of 115-230-Volt Distribution in a Modern Residential District" presented at a meeting of the Toronto Section, March 27, 1931.

**Plans for the Allocation of Sales Effort.**—As an aid in planning the approach to that portion of the industrial market found in manufacturing plants, the United States Department of Commerce recently released a bulletin "A Basis for Establishing Industrial Sales Territories." In announcing the bulletin, the department stated "To the experienced analyst this material will mean more up-to-date data upon which to adjust and check his present plan of allocating sales effort. However, to those charged with the responsibility of sales promotion in firms which have not established a marketing research department, the data undoubtedly will provide an inexpensive method of establishing quickly a fairly accurate marketing program." Copies may be purchased at 10 cents each from the Supt. of Documents, Govt. Printing Office, Washington, D. C.

## California Approves the Common Neutral

The use of a single combined neutral conductor for electric power distribution circuits operating at a potential of 5 kv. or less, has been approved by the California Railroad Commission for overhead construction, wherever feasible within that state, according to a news item in the May 1, 1932, issue of *Electrical West*. This decision comes after two and one-half years of intensive and extensive study and field tests, conducted under the supervision of the commission and with the cooperation of power and communication utilities and the National Electric Light Association. C. T. Mess (M'29) supervised the work for the commission.

One of the principal controversial points settled by the investigation and subsequent decision was the matter of telephone interference that might be caused by the new type of construction. The matter of safety was given close attention also, resulting in findings that, under the commission's construction specifications, the common-neutral system may be expected to be at least as safe for employees and the general public as the separate-neutral construction, and in many cases safer.

## Summer School for Engineering Teachers

Maintaining its previous practise, the Society for the Promotion of Engineering Education is planning to hold two summer school sessions for engineering teachers during July of this year. One session will be devoted to the study of economics and is to be held at Stevens Institute of Technology, Hoboken, N. J., July 5–21, 1932; a session on English is to be held at the Ohio State University, Columbus, Ohio, July 11–28, 1932. A registration fee of $10 will be charged for each session. Room and board at Stevens will be $50 per person for the period of the session; at Ohio State, $42 per person for the session. In both cases special arrangements will be made for those teachers who are accompanied by their wives.

Improvement of the teaching of engineering is stated as the general purpose of these sessions. Each session will be devoted to a study of the methods of teaching its particular subject or division of the engineering curriculum. Further information may be had from Frederic L. Bishop (A'13), secy., University of Pittsburgh, Pittsburgh, Pa.

## Electrification Report Issued

**Length of Railroad Track Electrified**

| Country | Miles Route | Miles Main Track | Miles All Tracks |
|---|---|---|---|
| United States..... | 2,055 | 3,597 | 4,911 |
| Switzerland....... | 1,542 | 2,105 | 2,929 |
| Italy............ | 1,079 | 1,620 | 2,218 |
| France........... | 1,046 | 1,736 | 2,234 |
| Germany.......... | 972 | 1,647 | 2,373 |
| Sweden........... | 726 | 791 | 1,039 |
| Austria.......... | 564 | 794 | 927 |
| Great Britain..... | 474 | 1,122 | 1,234 |
| Spain............ | 369 | 560 | 650 |
| Australia......... | 261 | 568 | 701 |
| Brazil........... | 251 | 272 | 319 |
| Japan............ | 248 | 441 | 569 |
| India............ | 222 | 455 | 689 |
| Chile............ | 208 | 242 | 365 |
| World total..... | 11,318 | 17,728 | 23,567 |

Electrification of steam railways throughout the world is covered exhaustively in the latest report of the railway electrification committee of the National Electric Light Association. This report is the fifth the committee has issued since a detailed study of steam railroad electrification was begun in 1926. Britton I. Budd, president of the Public Service Company of Northern Illinois, is chairman of the committee, and H. H. Field (A'14, M'28) is secretary.

The length of railroad track electrified, summarized in the accompanying table, is analyzed for the various countries. Existing electrifications are described, and among the new projects discussed are those of the Lackawanna, Reading, New York Central, and Pennsylvania railroads. After analyzing conditions in other countries, the report concludes with a study of the methods by which power is supplied to all the electrifications in the United States.

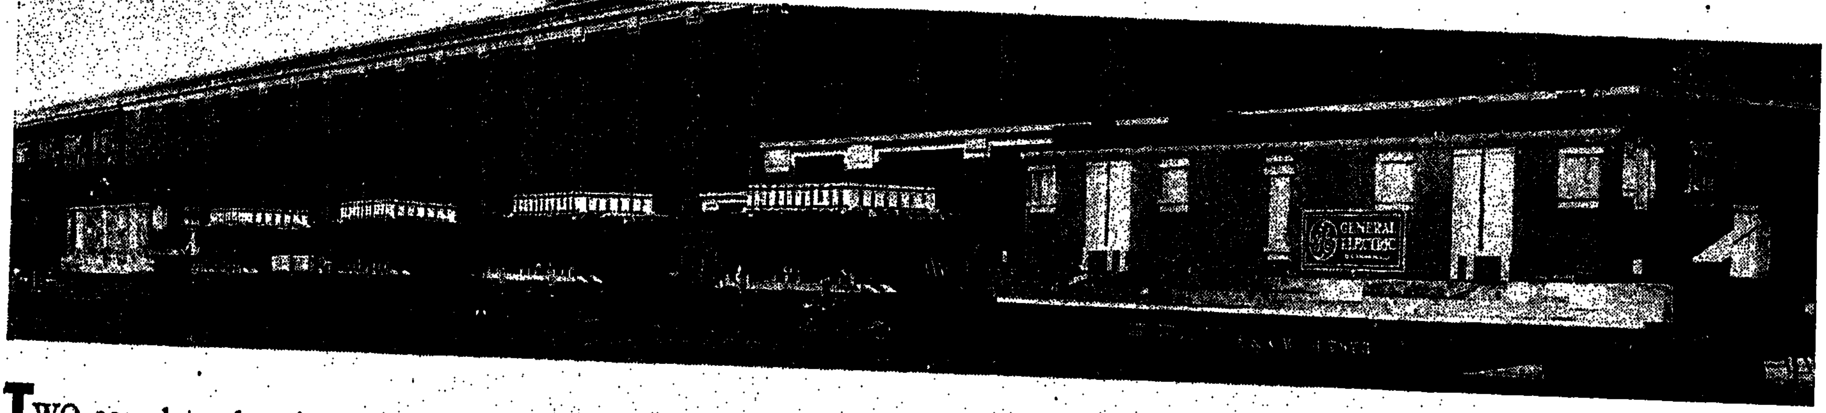
## Statistics on Consumer Markets

Newest data available indicating the location, size, and purchasing power of domestic markets for the products of American industry are presented in a report "General Consumer Market Statistics," made public by the Department of Commerce April 14, 1932. The report is published as the first supplement to the "Market Data Handbook of the United States" recently made available, and brings up to date the statistical information relating to the consumer market section.

Approximately how much money the people of a given section maintain in the bank, what proportion of them file income tax returns, how many automobiles they own, the number of wholesale and retail outlets that serve them—are a few of the fundamental factors entering into an appraisal of marketing possibilities which this new supplement brings together. Population, both city and rural, is shown for each county in the country as of the 1930 census count. Value of manufactured products, value added by manufacture, and worth of mine output, are reported on the basis of 1929 returns. Savings, deposits, postal receipts, and users of telephones, also are reported in terms of counties.

A large number of other tables and maps

## Two Electric Locomotives Shipped to U.S.S.R.



TWO complete electric locomotives, the first of eight for service on the Transcaucasian Railway in the U.S.S.R., have just been shipped from the Erie (Pa.) Works of the General Electric Company. Weighing 145 tons each, these two locomotives required six flat cars to transport them from the factory to New York, whence they were sent by ship to the Port of Batum through the Mediterranean Sea. The Transcaucasian Railway is part of the government owned system of the U.S.S.R.; it extends through the Suram Pass, the electrified section being about 40 miles in length, and including heavy grades. The locomotives, intended for both freight and passenger service, are of the six-axle type, and will be capable of being coupled together to form units of 290 tons and 5,400 hp., among the most powerful in Europe. Regenerative braking is provided. Tests on the locomotives are expected to be carried out during June, with complete electrical operation of the mountain section scheduled to begin in October of this year.

is given, some of these indicating the changes which have taken place since publication of similar data.

The "General Consumer Market Statistics" is published as part of a general program for providing American business with basic information which will enable the individual concern to increase the efficiency of its sales and marketing methods, and thus help to reduce wastes in the national distribution system. This publication may be purchased at 60 cents per copy from the Superintendent of Documents, Government Printing Office, Washington, D. C., or any of the district offices of the bureau located in principal cities. Copies of the third printing of "The Market Data Handbook" are available at $2.50 per copy.

# Letters to the Editor

## The Forces of Ignorance

*To the Editor:*

I have frequently in the past few months seen references to "the forces of ignorance, tradition" and so on, in various ELECTRICAL ENGINEERING articles; and now again in the March issue in Doctor E. W. Rice's address, as recorded on page 197, we have—"The forces of ignorance, tradition, and superstitition are strong and view with some alarm the progress of science" . . . "After all, the forces of reaction and ignorance cannot prevail permanently in a country in which the voters are properly educated."

Now, I for one of the readers of ELECTRICAL ENGINEERING would like to know just what these "ignorant, superstitious forces" are. Enough of this vague generalizing; if such forces exist let's have them named and combat them like intelligent beings, if they should be combated.

Yours truly,

FRANCIS L. BURKE (A'28)
(Mfg. Planning Engr., Western Elec. Co., Kearney, N. J.)

## Has Man Benefited by Engineering Progress?

*To the Editor:*

Through engineering progress man has revolutionized transportation and communication. He has harnessed the forces of nature and commands them do his bidding. He has appropriated for his use and entertainment all the marvelous inventions, developments, and improvements in the electrical, mechanical, chemical, and civil arts and sciences. Through engineering progress man has lightened his labors, increased his hours of leisure, expanded his means of entertainment, and increased his vision. But has man benefited by engineering progress?

This question cannot be answered affirmatively by merely enumerating the tremendous increase in economic wealth brought about by engineering progress. It is first necessary to come to an understanding of the significance of the word "benefited," the definition of the word being of but little assistance. The implication of the word "benefited" in any particular case is quite clear: a patient is benefited by the medical ministration that relieves his pain or restores his health, a sorely fatigued person is benefited by rest, a hungry person by food, the lonesome by companionship. But the patient aggravated by the best of potions, the man forced into idleness by unemployment, the farmer glutted with a surplus of food, the socially-lionized surfeited with companionship, certainly are not benefited. The objective, the result sought, as compared to that obtained, becomes a measure of the beneficialness of a man's acquisitions; it must result in a want satisfied.

Engineering progress is conceded by all to be the most powerful influence in the life of modern man. His work, his travel, his amusement, and his rest; his life and his health; his political, his social, and his home life, have all been affected or better still revolutionized. How can the benefit of such a deep and wide spread influence be measured? It can be done by finding man's objective, man's primary want and then inquiring as to what extent engineering progress satisfied that want. This primary want is, without question, happiness. Whatever man does, he does so because he thinks or believes that it will enhance his happiness. Even if his actions be entirely altruistic there is no denying the fact that he gains a measure of personal satisfaction from that act.

In the light of this primary want, has man benefited by engineering progress? The answer is that he has benefited but little, if at all. There are no available statistics to verify the truth or falsity of this statement. It is, however, easily observed that the greater happiness prevailing at the crest of a business cycle due to the higher standard of living made possible by engineering progress, is matched by an equal amount of misery at the trough of the same cycle; the latter seems to be in direct proportion to the former.

The man who has owned an automobile is as miserable when he can no longer afford the luxury, as the man who is compelled to move to a less pretentious apartment. It is the stepping down from an accustomed standard that brings on the state of unhappiness and not the particular height of the standard. This is attested to by the many visitors to our shores coming from less industralized countries. Each one would consider our present standard a godsend for his nationals. Several months ago an Englishman, upon leaving our shores, said that England would be a happy land if it were afflicted with the American depression. It is evident, therefore, that it is not the absolute status of the standard but the drop of same that hurts. Happiness during the rise is, therefore, offset by the unhappiness during the drop, leaving but a small sum total of benefit from engineering progress.

Engineering progress has been sporadically raising that standard; but the engineering profession, I regret to say, has made no attempt to so plan the progress as to make the rise smooth and uniform. Engineers have contributed all of the technical progress of mankind but have left to others the management or rather mismanagement of their contributions. Even to the present day many engineers look askance at the political and social activities of the professional engineering associations.

The engineer, accustomed to long-range planning, familiar with the industrial machine he has built, peculiarly trained for the job, should take a greater hand in the management of affairs. The national engineering societies could help much in bringing the engineer out of his purely technical shell. Assuming a little responsibility in investigating conditions, and the causes for same, and doing some planning for the future, and giving properly worked out plans suitable publicity, will certainly not hurt the engineering profession. In due time it may perhaps definitely be said that man is benefiting by engineering progress.

Yours very truly,

JACOB KATZMAN (A'20)
(Consulting Engr., Dumont Elec. Co., New York, N. Y.)

## Injuries From Electric Shock

*To the Editor:*

Referring to letters upon the general subject of vivisection that you have recently published, permit me a suggestion.

To alleviate the suffering of human beings we must have knowledge of a type that can be obtained only by experiment upon living organisms. The organisms may be either human or animal. When a human organism objects to the use of animal organisms for the benefit of himself and other human organisms, I think that it would be entirely proper for him to offer himself as a subject for the necessary experiments. Surely the objector will be willing to display in so practical a manner the humanitarianism that he has expressed with such feeling on paper.

I commend this suggestion to the attention of all those who would rather see a thousand children suffer than to have one of the lower animals put out of the way, under proper safeguards, to save the kids.

Very truly yours,

H. H. KETCHAM (A'13, M'23, Life Member) (Technical Editor, Forest Products Lab., Madison, Wis.)

## Injuries From Electric Shock

*To the Editor:*

I was very much interested in the articles by Dr. Kouvenhoven and others discussing the nature of injuries from electric shocks. All the utility engineers who have had occasion to testify in lawsuits involving personal injury, or who have heard the medical profession testify in such suits realize the lack of available information at the present time.

We are hopeful that experimental work will be continued and that the results will be made available to the electrical profession, as in the past.

Yours very truly,

E. E. GEORGE (A'20, M'29)
(Supt. of Electrical Operation, Tennessee Elec. Pwr. Co., Chattanooga, Tenn.)

# American Engineering Council

## Public Works Administration

The possibility of securing a public works administration during this session of Congress was greatly enhanced by the action of the House of Representatives on the omnibus economy bill. A special rule was obtained making the bill a part of the legislative appropriation bill, which will insure action upon its provisions by the Senate during this session of Congress. Title V of the bill authorizes the formation of the public works administration under an administrator who shall hold office for six years, and receive a salary of $10,000 per year. In its present form the bill provides that the rivers and harbors activities of the War Department be excluded from this administration. In passage through the house, but two minor perfecting amendments were made to this section, the effect of which was to make the provision applicable only to the officers of the corps of engineers and not to enlisted or civil service personnel.

The A.E.C. has sponsored several amendments to Title V of the bill to the effect that:

1. The term of office of the administrator of public works be extended to at least ten years.
2. Inasmuch as the administrator will deal with highly technical questions, definite stipulations as to his qualifications should be included in the bill.
3. Rivers and harbors work of the War Department should be under the administrator of public works.
4. The administrator of public works *may* (not *shall*) utilize the services of the corps of engineers of both the United States Army and Navy whenever and wherever practicable.
5. The administrator of public works be given authority to employ as special consultants, experts without civil service status.

The bill is now before the Senate where it is certain to receive some action within the near future. It seems highly probable that the Senate either will amend Title V or strike the entire section from the bill. Should this latter action take place, the president would have ample opportunity under another provision of the bill to group and consolidate into one given department all of the executive agencies having to do with public works construction.

**Muscle Shoals Bill Passed by House.**—On May 5, 1932, the House of Representatives passed the Muscle Shoals bill (HR11051). In many respects this bill is similar to the one vetoed by President Hoover last year, providing that the government may lease Muscle Shoals properties under certain conditions; in the event of its inability to lease the properties before a given time, the bill provides that they may be operated by the government.

**A.E.C. Gets New Member.**—The Society for the Promotion of Engineering Education recently became a member-organization of the American Engineering Council. This is regarded as an extremely important step in the development of the council inasmuch as the S.P.E.E. is the foremost exponent of engineering education in the United States.

# Personal

Adolph Shipek (A'23, M'29) design engineer for the Puget Sound Power and Light Company, Seattle, Wash., has been awarded the A.I.E.E. North West District 1931 prize for best paper. Mr. Shipek, a native of the State of Wisconsin, received his preliminary schooling at Antigo, and in 1909 was graduated from the electrical engineering course at the University of Wisconsin, Madison. Upon completion of his college course, he became a student apprentice with the Allis-Chalmers Company. During the following year he was engaged in construction work on the White River hydroelectric plant of the Puget Sound Power and Light Company, Seattle, Wash., and in 1911 he became draftsman on electrical substation installation for that company, continuing in this capacity for a period of four years. In 1918 he became chief electrician for the Norway Pacific Construction and Dry Dock Company at Everett, Wash. Two years later he was chosen mechanical and electrical draftsman for the Seattle School District, and was employed by the City of Seattle on its Skagit hydroelectric development. In 1921 he again became affiliated with the Puget Sound Power and Light Company, was made field engineer of that company in 1924, and later design engineer, the position he now holds.

ADOLPH SHIPEK

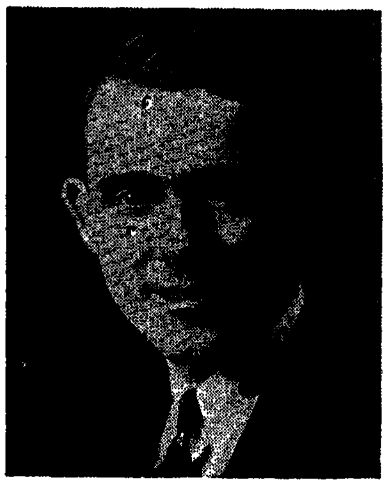
Gerard Swope (A'99, F'22) president of the General Electric Company, Schenectady, N. Y., has received the Gold Medal award of the National Institute of Social Sciences, "in recognition of his public service in formulating the Swope plan for the stabilization of industry with a guarantee of employment." The address of presentation was made by Owen D. Young, at the organization's annual dinner at the Waldorf-Astoria Hotel, New York, N. Y. In his speech of acceptance Mr. Swope expressed a satisfaction with the country's courageous attitude during the past two years. "Our primary thought for today," he asserted, "is how to emerge from these trying and difficult times as rapidly and as equitably as possible... If we are to maintain confidence, which is so absolutely essential, a definite program should be adopted toward balancing the budget of each of the various units in our country."

J. L. Watson (A'17) station meter tester for the Portland (Ore.) General Electric Company, has received the 1931 A.I.E.E. North West District prize for initial paper. Mr. Watson was born at Warren, Ohio, completed grade school and two years of high school at Meadville, Pa., then moved to Oregon and finished his high school course at Eugene. This was followed by a four-year course in electrical engineering at the University of Oregon (Eugene) from which he was graduated in 1915. After this he spent one term on a special course at Cornell University, Ithaca, N. Y., and a year on the General Electric test course at Pittsfield, Mass. At various times during his college years, Mr. Watson was employed as operator for the City of Eugene water works, for the Oregon Power Company at Eugene, and for the North Coast Power Company at Vancouver, B. C. He became affiliated with the Portland General Electric Company in 1920 and has been in the employ of that company since that time. He has taken a keen interest in Institute affairs and has served on many committees of the Portland Section.

J. L. WATSON

J. B. Whitehead (A'00, F'12) dean of the School of Engineering, Johns Hopkins University, and a member of its faculty since its organization, has been honored twice recently. He has been elected to membership in the National Academy of Sciences, the total membership of which is restricted to approximately 150 persons; and he has been awarded the Franklin Institute's Elliott Cresson Gold Medal and certificate for his work in dielectrics. The Elliott Cresson award was established in 1848 and is given "for discovery or original research, adding to the sum of human knowledge irrespective of commercial value;

leading to practical utilization of discovery; and invention, methods of products embodying substantial elements of leadership in their respective classes, or unusual skill or perfection in workmanship." The first award of this medal was made in 1856.



E. A. CHURCH

E. A. Church (A'29) who is now in the electrical engineering division of the Edison Electric Illuminating Company of Boston, Mass., was elected to receive the 1931 A.I.E.E. North Eastern District prize for initial paper. Mr. Church is a native of Franklin Grove, Ill. He was graduated from a cooperative course at Massachusetts Institute of Technology with the degree of S.M. in E.E. in June 1928. During his graduate year at M.I.T., Mr. Church was Swope Fellow in electrical engineering. He has been engaged with his present company ever since graduation, his work including various substation, transmission, and generation problems in connection with power system operation.

P. H. Moon (A'24, M'29) assistant professor in the electrical engineering department of Massachusetts Institute of Technology, Cambridge, Mass., has received the 1931 A.I.E.E. North Eastern District prize for best paper. A native of Beaver Dam, Wis., Mr. Moon was graduated from the University of Wisconsin in 1922 with the degree of B.S. in E.E. He was for a short while laboratory assistant for the Public Service Company of Northern Illinois at Joliet, Ill. After two years in the electrical and mechanical design schools of the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., he joined the staff of M.I.T. in 1924 as research assistant. He has made several contributions to A.I.E.E. literature.

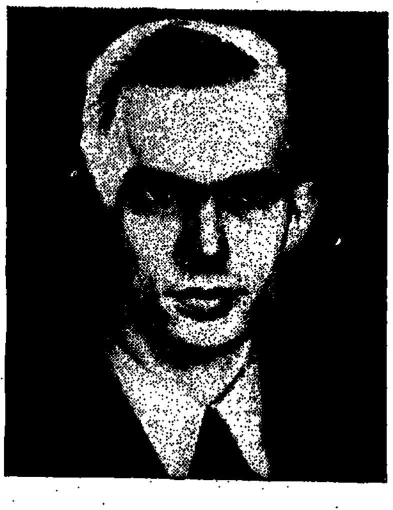
R. W. Alexander (A'28, M'30) formerly with Allied Engineers, Incorporated, and later with the Consumers Power Company, both of Jackson, Mich., has resigned his position with the latter company to join the Anaconda Wire and Cable Company, New York, N. Y. While with Allied Engineers, Incorporated, Mr. Alexander was connected with system planning. He has served on the power systems engineering committee of the National Electric Light Association.

M. Luckiesh (A'11, M'15) director of the General Electric Company lighting research laboratory at Nela Park, Cleveland, Ohio, recently received appointment to represent the United States National Committee on the technical committee on ultraviolet radiation of the International Commission on Illumination. The purpose of this committee is to define units and methods of measurement and for the appraisal of ultra-violet radiation.

F. D. Webber (A'09, M'30) who has been serving the Oregon Insurance Rating Bureau at Portland, Ore., as chief electrical engineer, recently was elected president of the International Association of Electrical Inspectors, the headquarters of which are in Chicago, Ill.; he is also secretary-treasurer of the Northwestern Section of this same organization. In his office as president he succeeds R. H. Manahan (M'22) of Los Angeles.

Richard McKay (A'22) assistant electrical engineer for the Washington Water Power Company, Spokane, Wash., has been appointed district manager of that company's Coeur d'Alene, Idaho, operations, which includes both electric and water service. His affiliation with this company dates from 1921, following his graduation from Columbia University, New York, N. Y. Mr. McKay is also chairman of the Associated Engineers of Spokane.

D. C. Robinson (A'32) who is at present a graduate assistant at the College of Applied Science, Syracuse University, Syracuse, N. Y., recently in his joint authorship with R. W. Stone, was voted the 1931 prize for Branch paper in the Institute's North Eastern District. Mr. Robinson, a native of Newell, Iowa, entered Syracuse University as a student in the electrical engineering department in 1927 and received his B.S. in E.E. in 1931. In the fall of 1931, he engaged with the General Electric Company to begin work in its vacuum tube research laboratory at Schenectady, October 1932. He now is working for his M.S. in E.E., his major teaching subject at the College of Applied Science being descriptive geometry. During the period from September 1930 to June 1931, he was chairman of the A.I.E.E. Branch at Syracuse University and also was chairman of the North Eastern District meeting Student session at Rochester, N. Y., May 1, 1931.



D. C. ROBINSON

Guglielmo Marconi (HM'17) recently was the recipient of the 1932 Kelvin Medal, which is awarded triennially by the Institution of Civil Engineers of Great Britain. The Kelvin Gold Medal, being a tribute of engineers to the memory of Lord Kelvin, is awarded to men of distinguished service in the application of science to engineering rather than in the development of physical science itself. The first award was made in 1920.

Frank Wenner (A'12, F'26) physicist, Bureau of Standards, Washington, D. C., recently was awarded the John Price Wetherill Medal, which The Franklin Institute presents annually "for discovery, invention, or development in the physical sciences." This medal award was established in 1925, for the promotion of research.

W. S. Watson (A'28) for many years chief engineer and manager of the city water and light supply for Hastings, Neb., recently received his appointment as superintendent of the board of public works at Hannibal, Mo. In this office he will be in charge of the Hannibal municipal supply of water, light, and power.

C. E. Allen (A'04, F'14) who for some time served the Westinghouse Electric and Manufacturing Company as its southwest district manager, with offices at St. Louis, Mo., and who is at present its commercial vice-president at East Pittsburgh, Pa., recently was elected vice-president of the American Management Association.

F. J. Bartlewski (A'28) who has been serving the International General Electric Company at Bucharest I., Roumania, now has been transferred by his company to Bombay, India. Prior to his work in Bucharest, Mr. Bartlewski was X-ray engineer for the General Electric X-Ray Corporation at Warsaw, Poland.

G. E. Wood (A'26) for some time a member of the firm of Langner, Parry, Card, and Langner, patent attorneys in New York, N. Y., has located in Dublin, Ireland, as assistant patent agent for Cruickshank and Company, an organization which has been operating for over thirty years and closely allied with Mr. Wood's previous connection.

E. W. Davis (A'15, M'21) has been made electrical engineer for the Simplex Wire and Cable Company, Cambridge, Mass. He succeeds W. I. Middleton (A'09, M'14) who was forced to retire a short time ago because of ill health. Mr. Davis' previous office with the company was that of assistant electrical engineer.

J. C. Parker (A'04, F'12) was recently appointed to the board of directors of the American Standards Association, to succeed M. S. Sloan (A'07, F'30) whose term expired December 1931. Mr. Parker represents the electric light and power group on that board.

**R. B. May** (A'12) for several years has been vice-president and assistant managing director of the Overseas Motor Service Corporation, New York, N. Y.; now he has removed to Chicago to become curator of automotive engineering at the Museum of Science and Industry in that city.

**H. W. Fisher** (A'95, F'12) who is a Member for Life of the Institute and who for some time has been consulting engineer for the General Cable Corporation, located at Perth Amboy, N. J., now has retired from active service. His future address will be Laguna Beach, Calif.

**W. J. Berry** (A'31) is now assistant equipment supervisor of the Southeast Missouri Telephone Company, and is located at Cape Girardeau, Mo. As a student engineer of the General Electric Company, Mr. Berry was located previously at Lawrence Park, Erie, Pa.

**C. O. von Dannenberg** (A'06, M'30) who formerly was assistant electrical engineer of the Electric Management and Engineering Corporation, New York, N. Y., recently became a member of the engineering department of the Pennsylvania Central Light and Power Company, Altoona, Pa.

**C. M. Gilt** (A'21, M'26) outside plant engineer for the Brooklyn Edison Company, Brooklyn, N. Y., has received the appointment of assistant electrical engineer of that company. Mr. Gilt's first connection with the Brooklyn Edison Company was as test engineer in 1923.

**V. M. Graham** (A'23, M'29) radio engineer for the Stromberg-Carlson Telephone Manufacturing Company, at Rochester, N. Y., recently was appointed chairman of the standards section of the Radio Manufacturers Association of New York, N. Y.

**Edward Allen** (A'30) field engineer for the Public Service Company of Northern Illinois, has been transferred from the Maywood (Ill.) territory to Harvey, Ill., were he will continue in the capacity of field engineer.

**William Arthur** (A'12, M'17) previously located in New York, N. Y., as assistant to vice-president, American Brown Boveri Company, now should be addressed in care of Allis-Chalmers Manufacturing Company, New York, N. Y.

**W. H. Harrison** (A'20, M'30) plant engineer for the American Telegraph and Telephone Company, New York, N. Y., at a recent election was chosen to serve on the executive committee of the A.I.E.E. New York Section.

**F. A. Lavigne** (A'26) who for many years has been local manager of the Associated Wholesale Electric Company at Los Angeles, Calif., now has associated himself with The Electric Material Company, Inc., of San Francisco.

**S. A. Smith, Jr.** (A'24) assistant transmission engineer for the Public Service Electric and Gas Company, Newark, New Jersey, has been made chairman of the power group of the Institute's New York Section for 1932–1933.

**I. S. Coggeshall** (A'30) general traffic supervisor of the Western Union Telegraph Company, New York, N. Y., recently was elected to the chairmanship of the communication group of the Institute's New York Section for 1932–1933.

**W. T. Blackwell** (A'22) general lighting representative of the Public Service Electric and Gas Company, Newark, N. J., has received reelection as chairman of the illumination group of the Institute's New York Section for 1932–1933.

**H. C. Dean** (A'12, F'30) general superintendent of the New York and Queens Electric Light and Power Company, Flushing, N. Y., has been elected to serve for 1932–1933 on the executive committee of the Institute's New York Section.

**J. D. Carroll** (A'21) formerly assistant engineer of the Electric Bond and Share Company, New York, N. Y., now is serving the Public Service Commission of Maryland, at Baltimore, in like capacity.

**R. W. Stone** (A'32) of the sales department of the Oswego Motor Car Company, Oswego, N. Y., shares with **D. C. Robinson** (A'32) the North Eastern District prize for the Branch paper for 1931. Oswego is Mr. Stone's native city. He received his B.S. in E.E. from Syracuse University with the class of 1931, and the summer between his junior and senior years worked for the American Telephone and Telegraph Company, New York, N. Y., in the transmission engineering department, where his work consisted chiefly of becoming acquainted with the various phases of telephone work in connection with carrier telephone systems and central offices, radio program transmission, and telephone plant maintenance.

R. W. STONE

**J. R. Batcheller** (Enrolled Student) Oregon State Agricultural College at Corvallis, Ore., has been awarded the Institute's North West District prize for Branch paper presented during 1931. The award was made for Mr. Batcheller's paper, "Abridged Method of Testing Welds," presented at a joint meeting of the Oregon State College Branch and the A.I.E.E. Portland, Ore., Section, May 23, 1931. The author is a native of Portland and is continuing his studies at the Oregon State college, where he took a course in electrical engineering and from which he was graduated in 1931 with his B.S. degree.

J. R. BATCHELLER

**G. R. Dittwe** (A'26) until recently sales engineer for the Garland-Affolter Engineering Corporation at Los Angeles, Calif., is now manager of Electric Agencies at Oakland, Calif.

**J. E. Woods** ('30) assistant chief engineer of the Central Power and Light Company, San Antonio, Texas, as of April 14, 1932, was transferred to Guero, Texas, where he continues to serve the company.

**C. O. Evans** (A'22) who has been serving the British American Metals Company of New York, N. Y., as secretary, now is secretary of the British-American Tube Company, New York, N. Y.

**W. P. Hammond** (M'20) formerly engineer of generating plants, Allied Engineers, Incorporated, Birmingham, Ala., now has become general engineer of the Georgia Power Company at Atlanta, Ga.

**T. F. Barton** (A'12, F'30) district engineer for the General Electric Company, New York, N. Y., is the new chairman of the New York Section of the Institute, to hold office during the fiscal year 1932–1933.

**W. R. Smith** (M'18, F'30) assistant chief engineer, United Engineers and Constructors, Inc., Newark, N. J., has been elected secretary of the Institute's New York Section for 1932–1933.

**L. L. Edgar** (A'12) vice-president in charge of the operating bureau of the Edison Electric Illuminating Company of

Boston has succeeded his father in the office of regional director for New England of the refrigeration bureau of the National Electric Light Association.

# Obituary

**Benson Osborn Ellis** (M'23) operating manager of the Cia Anglo Argentina de Electricidad, S. A., died there of cerebral hemorrhage, October 1931, according to information received recently. He was born in Corina, Maine, September 24, 1873, and was a graduate of the high school at Dexter, Maine. In 1890 he engaged with the Brunswick Electric Light and Power Company, Brunswick, Maine, as station operator, having worked previously on inside wiring and line construction. Three years later he joined the Knox Gas and Electric Company and the Rockland, Thomaston and Camden Street Railway Company, Rockland, Maine, as construction foreman in charge of overhead work, inside wiring, customers' installations, and also operation of the power plant. In this position he remained for four years, after which he went to Astoria, N. Y., in 1897, where he became electrical superintendent in charge of power plant operation, overhead line construction, and customers' installations for the Astoria Electric Light and Power Company. Later he was associated with William Sheehan and Company, contracting engineers, New York City, in charge of the design and construction of small central station installations. In 1906 he became construction superintendent of the J. G. White & Company, Inc., taking over the general charge of new power plant and substation construction, high voltage transmission, and street railway extensions and repair for the Eastern Pennsylvania Railway Company, Pottsville, Pa. His next change came in 1908 when he went with the Columbia Power, Light and Railways Company as general manager in charge of rehabilitation and operation of street railway, and gas and electric light properties, in Berwick, Bloomsburg, and Danville, Pa. In 1910 he returned to the J. G. White organization and was active on many important projects. He was placed in charge of powerhouse extension, substation, and underground work and the rebuilding of street railway lines for the Wilmington and Philadelphia Traction Company, Wilmington, Del.; in 1912 he was sent to take charge of powerhouse and substation construction, transmission line erection, and low voltage distribution for an electric company in Venezuela; and in 1914 he was sent to take charge of the building of the street railway system for the Quito Tramways Company, Quito-Ecuador, S. A. The last named connection led to his appointment as general manager and chief engineer of the Quito Tramways Company and the Quito Electric Light and Power Company. In 1923 he returned to the United States and established an electrical engineering and construction business of his own in New York City. In this he continued until he went to Cuba to take charge of electrical engineering and construction for the Cuban Electric Company at Havana. The year 1927 found him division manager of the Florida Power and Light Company, at Sarasota, Fla., the position which he left when he was made assistant to the president of the Public Utilities Consolidated Corporation, at Minneapolis, Minn., in 1929. Immediately prior to his last position in Argentina, he was president of the Central American Power Corporation at Nicaragua.

**Henry E. McGowan** (M'17), secretary of the Brooklyn (N. Y.) Union Gas Company, died at the Long Island College Hospital, Brooklyn, N. Y., May 7, 1932. He had been with that company for 24 years. Mr. McGowan was a native of Brooklyn; his early education was obtained at private schools and included five years of military training. In 1889 he went to the Stevens Institute preparatory school and in 1894 was graduated from Stevens Institute with a degree in mechanical engineering. For the next three years he was process chemist for Church and Company, Trenton, Mich., a concern manufacturing soda by a special ammonia process. In this connection, Mr. McGowan first served a term in the company's laboratory immediately under the chief chemist and in complete charge of process of production. In 1898 he went with the Brooklyn Union Gas Company as electrical engineer, his chief duties being to investigate the matter of electrolytic damage to sub-surface plant, and to follow up prospects for gas-engine-driven electric installations. In addition to these duties, in 1903 he was elected general manager of the Flatbush Gas Company. This company was a subsidiary of the Brooklyn Union Gas Company, but carried on an electric power business in addition to its gas distribution activities. In this affiliation all extensions of electric station and distribution equipment were carried out directly under Mr. McGowan's supervision and direction, including the purchasing of all turbo-generators, boilers, condensers, and other necessary equipment, and the prescribing of the systems and designs to be employed. In 1914 he was made assistant secretary of the Brooklyn Union Gas Company, at the same time holding like office in five of its subsidiaries, and in addition retaining the title of general manager at the Flatbush Gas Company. Mr. McGowan has contributed two articles to technical literature: "Electrolysis, the Effect of Stray Trolley Currents," published in the *Stevens Indicator*, and a "Remedy for Electrolytic Damage to Mains," published in *Progressive Age*. He was a member of the National Electric Light Association, the Brooklyn Chamber of Commerce, the American Gas Association, and The American Society of Mechanical Engineers. He held membership also in the Crescent Athletic-Hamilton Club.

**Carl Leo Mees** (A'03) president emeritus of Rose Polytechnic Institute, Terre Haute, Ind., and prominent as a scientist and medical authority, died at Terre Haute, April 19, 1932. He was born at Columbus, Ohio, May 20, 1853, and in due course of time became a student at Ohio State University. This schooling was amplified by a course at the University of Berlin, Germany, with study under the eminent physicists, Hermann Helmholtz and Gustav Kirchhoff. In further pursuit of knowledge, he went to South Kensington, England; then, returning to the United States and his native city, he entered the Starling Medical College at Columbus, Ohio, but never practised medicine. In 1871 as chief chemist he was with the Ohio geological survey and state gas commission, and four years later became professor of physics and chemistry at the University of Louisville, Ky. From 1881 to 1887 he was professor of chemistry and physics of the newly organized Ohio University at Athens, Ohio, later in 1887 assuming his professorship at Rose Polytechnic Institute as teacher of physics and electricity. His presidency there extended over the period from 1895 to 1919, when he resigned the active presidency and became president emeritus. Perhaps the best known of Doctor Mees's achievements was the development of a process making possible microscopic photographs of human blood and minute tissues. This process was adopted by the Army and Navy research departments, and was employed nationally in the detection and solution of crime. He was a Fellow of the American Association for the Advancement of Science, of which he was also general secretary in 1889 and a vice-president in 1896; his other memberships included the American Physical Society, the Society for the Promotion of Engineering Education, and the Indiana Academy of Science. He was also an honorary member of the State Credit Men's Association. Doctor Mees was the author of many scientific papers and contributions to technical literature.

**Harry N. Van Deusen** (A'19, M'30), materials engineer for the Bell Telephone Laboratories, Inc., New York, N. Y., died suddenly May 15, 1932, at the Easton Hospital, Easton, Pa. He was born at Columbia, N. J., December 3, 1884, and was graduated from Purdue University, Lafayette, Ind., in 1907 with the degree of B.S. in E.E. In June 1907 he engaged with the maintenance department of the Chicago Telephone Company (Ill.), where he gained a varied experience in central office testing, outside testing and installation, and inspection of central office equipment. March 1909 he returned to the University of Purdue as professor of machine design, remaining in this teaching capacity until the end of the school term. He then became equipment engineer of the Western Electric Company, at Hawthorne, Ill., and continued there until 1912, when he was transferred to the engineering department of the Company in New York. In 1925 he became a member of the technical staff of the Bell Telephone Laboratories, Inc., and was at the time of his death one of its workers in the analytical study of magnetic materials, insulating materials, protection apparatus and the analysis and testing of all types of telephone apparatus. A resident of East Orange, N. J., for the past twenty years, he was chairman of the insulating materials committee of the American Society for Testing Materials, a member of the New York Electrical Society, and was the Bell Telephone Laboratories' representative in the American Welding Society.

**William H. Hill** (A'04) superintendent of electrical construction for the New York Edison Company, and an employee of that company for 42 years, died May 4, 1932, after a short illness. He was 66 years of age. Born in Philadelphia, Pa., Mr. Hill started his electrical career, in 1888, as a splicer's helper with the Philadelphia Edision Company. Approximately ten years later he became a splicer for the Toronto Edison Company. The following year he returned to the United States and engaged with the New York Edison Company, then the Edison Electric Illuminating Company, still as a splicer of cables. From then on his promotion was rapid; in 1902 he was made foreman, a year later being advanced to general foreman, the next year to assistant superintendent of electrical construction, and shortly thereafter to the office he last held, superintendent of electrical construction. His effort with the New York Edison Company was not restricted to purely departmental activities, for it was through his instrumentality that the Edison Company's Employees' Association was founded, Mr. Hill being placed in the presidency of that organization. He was a member of the Edison Pioneers.

**Louis George Freeman** (A'16) for more than twenty years in charge of the lighting, power, and signal systems, and the design and installation of simple laboratory apparatus for the U. S. Geological Survey, Washington, D. C., died December 8, 1931, according to word recently forwarded to Institute headquarters. Mr. Freeman was born at Washington, D. C., January 27, 1869, and after public schooling, spent three years at George Washington University, Washington, D. C.

# Local Meetings

## Student Convention Held in New York

A highly successful student convention was held on April 29, 1932, at Institute headquarters by the several Branches within the territory of the Institute's New York Section. Eight Branches participated as follows: Brooklyn Polytechnic Institute, Cooper Union, Newark College of Engineering, College of the City of New York, New York University, Pratt Institute, Rutgers University, and Stevens Institute of Technology.

The morning session was devoted to inspection trips to various nearby points of interest. During the afternoon session, a talk on "Photofilms" was given by Dr. Johnson O'Connor (A'22) of Stevens Institute, after which a dinner was held at the Hotel McAlpin. A joint student meeting and general Section meeting was held during the evening.

The first portion of the evening program was devoted to the presentation of three student papers entered in competition for the New York Section student-paper prizes. The first prize of $25 went to Russell Buehl of Brooklyn Polytechnic Institute for his paper "Frequency Control by Means of the Thyratron Tube"; second prize of $10 to E. Olsta of Newark College of Engineering, for his paper "Carrier Current Communication as a Factor in the Stability of Power Systems." The awards were made by a group of prominent New York Section engineers.

During the second portion of the evening session, Dr. Frank B. Jewett (F'12 and past-president), vice-president, American Telephone and Telegraph Company, New York, gave a talk on "What the World Expects of the Electrical Engineer." "Graduates of the present period," said Doctor Jewett, "do not find before them the rosy outlook enjoyed by graduates of a few of the preceding years. Nevertheless on the basis of my own life-work I believe that a hard path at the start of a professional career is of tremendous value as a character builder and developer of the best traits."

Later in his address Doctor Jewett declared: "The past 50 years' work has been *creative;* now we have entered into a period which has an objective slightly different from that of the period just passed. There have been so many developments, and they have been prosecuted so individually that now more than ever the problem of coordination looms up as of prime importance not only within the technical field of the electrical engineer, but also in the relation of that field to every-day life. Coordination inevitably will be the, or one of the, most compelling problems challenging the electrical engineer in the future."

### Method of Judging Student Papers

Because of the success of the method used by the committee in judging the papers, a brief outline of this method is presented herewith in the belief that it may be of some value to other committees facing similar problems. Each Branch was allowed to submit one paper for the competition; the written papers then were rated independently by three judges on the basis of the following points:

| | |
|---|---|
| Grasp of subject | 10 points |
| Arrangement of material | 10 points |
| Constructive character of ideas | 10 points |

The three papers receiving the highest number of points in this first rating were selected for presentation at the convention, where the judges of the oral presentation rated them on the following basis:

| | |
|---|---|
| Clarity | 10 points |
| Force of expression | 10 points |
| General platform decorum | 10 points |

All Branches participating in the contest were informed in advance regarding details of the plan to be used; thus all contestants knew beforehand upon just what basis their papers would be judged. This common understanding, together with the fact that the judges were given definite points upon which to rate the papers are believed to be the two principal features contributing most toward the workability of the plan. The practicability and success of the system was demonstrated by the close agreement reached by the judges, all of whom worked individually.

## Schenectady and Pittsfield Sections Hold Competition

Following the plan inaugurated three years ago to encourage their younger members to participate in programs, the Schenectady and Pittsfield Sections held joint meetings in Schenectady, April 7, 1932, and Pittsfield, April 13, 1932, for the presentation of papers by section members less than 30 years of age, who had not previously presented Institute papers. The programs were as follows:

**Schenectady**

Protection of Underground Structures From Corrosion, by F. K. Fox, Pittsfield.
Calculation of Two Machine Stability With Resistance, by S. R. Pritchard, Schenectady.
The Blowing of Fuses by Impulse, by T. Brownlee, Pittsfield.
Increasing Stability Limit of Generators, by S. B. Crary, Schenectady.
Electrical Music, by A. H. Foley, Pittsfield.
X-Ray and Cathode Ray Tubes in the Production of New Forms of Life, by C. P. Haskins, Schenectady.

**Pittsfield**

Voltage Drop Calculations for Long Transmission Lines, by R. N. Slinger, Schenectady.
Measurement of Current in Impulse Circuits With the Cathode Ray Oscillograph, by S. W. Zimmerman, Pittsfield.
Design of Type D Carrier Telephone Facilities, by S. E. Benson, Schenectady.
Lightning Investigation on Transmission Lines, by H. E. Pierce, Pittsfield.
Startling Starts and Stops—Unusual Synchronous Motor Performance, by C. E. Kilbourne, Schenectady.
Thyratron Commutated Motor, by G. E. Nonken, Pittsfield.

Prizes were awarded after consideration of the contents of the papers as well as the presentation. At the Schenectady meeting, C. P. Haskins of Schenectady received the first prize, and S. R. Pritchard of Schenectady received second prize. The attendance was 250.

At the Pittsfield meeting, C. E. Kilbourne of Schenectady received the first prize and R. V. Slinger of Schenectady received the second prize. The combined prize, the F. W. Peek, Jr., cup, went to the Schenectady Section who are permanent holders since they won it two out of three years. The attendance was 175.

# Future Section Meetings

**Detroit-Ann Arbor.** June 21—spring frolic.

**Louisville.** June 3—Outdoor recreation meeting. Annual election of officers.

**Vancouver.** June 6—Annual dinner.

# Past Section Meetings

**Akron**

Inspection trip to the Ohio Edison Company's East Akron substation. The Load Shifting Transformers at Salt Springs, by J. H. Foote and L. N. Gozinski. Feb. 9. Att. 45.

Electric Refrigeration and Air Conditioning, by W. M. Timmerman, Genl. Elec. Co. The Electrical Industry and Some Problems of the Institute, by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. April 12.

**Atlanta**

C. H. Dolan, Eastern Air Transport, and C. R. Whittaker, vice-consul, Foochow, China, gave talks on the Sino-Japanese situation. Joint meeting with A.S.M.E. Sec. March 21. Att. 75.

**Baltimore**

Material Handling, by H. V. Schmidt; Electrical Distribution System, Point Breeze Works, by W. A. Halliday; Power House, Point Breeze Works, by E. F. George; all of the Western Elec. Co. Films—"New Voice Highways" and "Modern Knight." Joint meeting with A.S.M.E. Dinner. April 14. Att. 180.

**Boston**

A General Description of the Lackawanna Electrification, by E. L. Moreland, Jackson & Moreland. Film—"On the Pathways of Progress." April 21. Att. 105.

**Chicago**

Design and Operation of Overhead Lines in Relation to Continuity of Service, by F. E. Andrews, Pub. Serv. Co. of No. Ill. March 17. Att. 115.

Rates and Rate Making, by F. E. Kruesi, Middle West Utilities Co. April 14. Att. 95.

Development of the Use of Electricity in Steel Mills, by C. J. Smith, Ill. Steel Co. Election of officers: L. R. Mapes, chmn.; E. C. Williams, vice-chmn.; D. L. Smith, secy.-treas. Joint meeting with Western Soc. of Engrs. May 2. Att. 134.

**Cleveland**

Electric Refrigeration and Domestic Air Conditioning, by W. M. Timmerman, Genl. Elec. Co. Illus. April 21. Att. 56.

**Columbus**

A-C. Networks, by F. W. Marquette, Columbia Ry. Pwr. & Lt. Co. Jan. 8. Att. 36.

Recent Telephone Research and Its Application, by S. P. Grace, asst. vice-pres., Bell Tel. Labs., Inc. Joint meeting with the A.S.M.E., A.S.C.E., Engrs.' Club, and Electric League of Columbus. Jan. 22. Att. 3485.

George Washington, Engineer, Business Man, and Statesman, by C. T. Marshall, Chief Justice Supreme Court, State of Ohio. Joint meeting with A.S.C.E., A.S.M.E., Engrs.' Club, in cooperation with George Washington Bicentennial Committee. Feb. 26.

Electric Shock, by Dr. W. B. Kouwenhoven, Johns Hopkins Univ., vice-pres. A.I.E.E. Joint meeting with Ohio State Univ. Branch. Dinner. April 22. Att. 44.

**Connecticut**

Moulded Plastics, by F. J. Groten, Genl. Elec. Co. Feb. 16. Att. 65.

**Dallas**

The Coordination of Line and Station Design for Lighting Surge Conditions, by A. O. Austin, Ohio Brass Co. April 11. Att. 81.

**Denver**

Rural Electrification, by C. A. Lory, Colorado Agri. Col. Dinner. April 15. Att. 70.

**Detroit-Ann Arbor**

Commercial Metering of Electric Energy, by A. S. Albright, Detroit Edison Co. April 19. Att. 150.

**Florida**

Business meeting in Jacksonville, April 14, during spring meeting of Florida Engg. Soc., April 14–16. Reports by secretary and chairmen of membership and student activities committees. Appointment of nominating committee. Joint dinner on evening of April 14 of Florida Engg. Soc., and A.S.C.E., A.S.M.E., and A.I.E.E. Sections and Branches, Att. 20.

**Fort Wayne**

Reactance in Transformer Design, by J. F. Eitman, Genl. Elec. Co.; Transformers With Peaked Secondary Voltage Wave, by O. Kiltie, Genl. Elec. Co. Demonstrations. April 14. Att. 40.

**Houston**

Coordination of Line and Station Design for Lighting Surge Conditions, by A. O. Austin, Ohio Insulator Co. April 15. Att. 28.

**Indianapolis-Lafayette**

The Electrical Industry of Today, by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. Dinner. March 31. Att. 95.

The Corpuscular Theory of Light, the Wave Theory of Matter, the New Physics, by Prof. C. T. Knipp, Univ. of Ill. Joint meeting with Purdue Univ. Branch. April 26. Att. 205.

**Ithaca**

High Spots in the Design of Steam Electric Power Plants, by I. E. Moultrop, vice-pres., A.I.E.E., Chief Engr., Edison Elec. Ill. Co. of Boston. March 9. Att. 50.

**Kansas City**

General Features of Telegraph Service as Used in the Bell Telephone System, by B. A. Kahn, Southwestern Bell Tel. Co. April 18. Att. 48.

Adventures in Science, by E. L. Manning, Genl. Elec. Co. Meeting held in cooperation with the engineering societies of Kansas City, under the auspices of the Electric and Radio Assn. April 21. Att. 875.

**Lehigh Valley**

Power System Operation, by G. M. Keenan, Pa.-N. J. 220 Kv. Interconnection. Inspection trip through the Metropolitan Edison Co. Nov. 13, 1931. Att. 124.

Electrical Power in the Anthracite Fields and Its Application to Coal Mining, by W. H. Lesser, Penn Anthracite Mining Co. Inspection trip through the new Locust Summit central breaker of the Phila. and Reading Coal & Iron Co. Dec. 11, 1931. Att. 122.

Primary Network Distribution Systems, by D. K. Blake, Genl. Elec. Co. Jan. 15. Att. 176.

Research—Industry's Health Insurance, by S. M. Kintner, Westinghouse Elec. & Mfg. Co. Joint meeting with the Engrs.' Club. March 18. Att. 122.

**Los Angeles**

Radio Interference, by Prof. J. K. McNeely, Calif. Inst. of Tech. Dinner. April 12. Att. 86.

**Louisville**

Fundamentals of Plane Construction and Flight, by A. W. Lee, Louisville Gas & Elec. Co. Inspection trip through the Bowman Field airport. April 15. Att. 450.

**Lynn**

What Are You Afraid of? by Dr. Charles Newcomb. Banquet. April 9. Att. 194.

**Madison**

Prospecting in Science, by M. W. Hanks, Hankscraft Co. Dinner. April 20. Att. 65.

**Memphis**

Dredging Operations From the Time of the Civil War Up to the Present Date, by Major H. S. Gladfelter. April 12. Att. 33.

**Mexico**

Thermodynamic Considerations on the Modern Steam Turbine, by G. A. Schulenburg, A. E. G. Co. Dinner. March 17. Att. 28.

J. Herandez Olmedo described the organization and systems used by the National Telegraphs. Illus. Dinner. April 14. Att. 31.

**Milwaukee**

Television, by Sam Snead, Univ. of Wis. Joint meeting with the Engrs. Soc. of Milwaukee. Dinner. March 23. Att. 450.

**Minnesota**

Demonstration and lecture by S. P. Grace, asst. vice-pres. Bell Tel. Labs., Inc. Joint meeting with the Univ. of Minn. Branch. April 14. Att. 5000.

**Montana**

Light and Illumination, by Prof. J. A. Thaler and Prof. F. C. Bowman, Mont. State Col. Joint meeting with Montana Soc. of Engrs. April 11. Att. 60.

**Nebraska**

Lighting and Its Relation to Electric Apparatus, by Dr. C. L. Fortescue, Westinghouse Elec. & Mfg. Co. Dinner. March 18. Att. 80.

**New York**

Recent Developments in Radio Broadcasting, by R. L. Davis, Westinghouse Elec. & Mfg. Co., and E. W. Wallace, Am. Tel. & Tel. Co. March 15. Att. 300.

Regulation of Power Flow Between Interconnected Systems, by H. L. Melvin, Elec. Bond & Share Co., and J. B. McClure, Genl. Elec. Co. April 15. Att. 325.

Electric Locomotives on the Pennsylvania, by J. V. B. Duer, Penn. R.R. April 19. Att. 425.

**Niagara Frontier**

Nominating committee meeting. March 28.

Surge Proof Power Transformers, by H. V. Putman, Westinghouse Elec. & Mfg. Co. Illus. Election of officers: F. S. Wahl, chmn.; J. F. Oehler, secy.-treas. Dinner. April 15. Att. 90.

**North Carolina**

Spring meeting opened with address of welcome by Mr. House, Univ. of No. Carolina. Valuation for Rate Making, by R. O. Self, No. Carolina Corp. Comm.; Arc Welding as Applied to Manufacturing Processes, Covering Both Machinery and Buildings, by C. I. MacGuffie, Genl. Elec. Co.; Surge Proof Distribution Transformers, by H. D. West, Westinghouse Elec. & Mfg. Co.; Illumination for the Future, by R. A. Palmer, Southern Pub. Utilities Co. Illus. Short talk by W. S. Lee, past-pres., A.I.E.E., pres. W. S. Lee Engg. Corp. Dinner. April 5. Att. 180.

**Oklahoma City**

Vertical Transportation, by R. W. Van Kirk, Genl. Elec. Co. Discussion. March 21. Att. 60.

The Coordination of Line and Station Design for Lightning Surge Conditions, by A. O. Austin, Ohio Insulator Co. Dinner. April 21. Att. 90.

Adventures in Science, by E. L. Manning, Genl. Elec. Co. Demonstrations. April 25. Att. 1430.

**Philadelphia**

The Engineer's Professional Status, by Dr. W. E. Wickenden, Case Sch. of Ap. Sc. March 14. Att. 210.

The Institute and the Electrical Industry—What of Their Future? by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co.; Public Interest in Science, by Fred F. Shedd, managing editor, *Phila. Evening Bulletin.* April 11. Att. 160.

**Pittsburgh**

The Electrical Industry of Today, by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co.; How to Interest the Public in Engineering News, by Mark Shields, *Pittsburgh Sun-Telegraph;* Rambling With Reichhold, by Ralph Reichhold, Pittsburgh Press artist; Electrifying a Specialty, by Dr. Charles Wales. Joint meeting with the Engrs. Soc. of Western Penn., and Carnegie

Inst. of Tech., Univ. of Pittsburgh, and Univ. of West Virginia Branches. Jan. 12. Att. 340.

Pittsburgh's Contribution to Radio Development, by S. M. Kintner, Westinghouse Elec. & Mfg. Co. Joint meeting with Engr. Soc. of Western Penn., held in connection with the annual convention of the I.R.E. April 7. Att. 500.

### Pittsfield

The Science and Theory of Magnetism, by Dr. S. R. Williams, Amherst Col. E. G. Newton received a prize for presenting the best paper before the Section during 1931. Dinner. April 22. Att. 110.

### Portland

Surge-Proof Transformers, by A. W. Copley, Westinghouse Elec. & Mfg. Co., vice-pres. A.I.E.E. April 12. Att. 52.

### Providence

Communication Systems Which Compromise the International Tel. & Tel. Network, by A. A. Clokey, Intl. Tel. & Tel. Co. Demonstrations. April 20. Att. 200.

### Rochester

Program Service Systems, by A. E. Soderholm. Jan. 14. Att. 69.

How a Modern Radio Station Functions, by Wm. Fay, Stromberg-Carlson Mfg. Co. Joint meeting with the I.R.E. Feb. 11. Att. 319.

Modern Manual Telephone Practise, by Mr. Vincent and Mr. Gillespie, Rochester Tel. Corp. March 3. Att. 94.

Changes in Methods of Industrial Development as a Result of Industrial Research, by Dr. F. B. Jewett, vice-pres., Am. Tel. & Tel. Co., and pres. Bell Tel. Labs., Inc. Demonstrations by Mr. L. S. O'Roark, Bell Tel. Labs., Inc. March 28. Att. 400.

The Application of Engineering Principles to the Production of Artificial Fever, by Dr. Stafford L. Warren. Joint meeting with the I.R.E. April 7. Att. 133.

### St. Louis

Heating and Overload Protection of Polyphase Motors, by C. P. Potter, Wagner Elec. Corp. Election of officers: F. B. Wipperman, chmn.; Ralph Kelley, vice-chmn.; S. L. Hilyard, secy. April 20. Att. 85.

### San Antonio

The Coordination of Line and Station Design for Lightning Surge Conditions, by A. O. Austin, Ohio Insulator Co. Illus. Dinner. April 18. Att. 110.

### San Francisco

The Precise Electrical Measurement of Short-Time Intervals, by Wm. McLeod, Univ. of Calif.; Influence of Conductor Temperature on Corona Loss, by A. K. Nuttall, Stanford Univ.; The Application of the Inverted Vacuum Tube to the Measurement of Voltages, by L. W. Thorpe and R. Sheridan, Univ. of Santa Clara, Joint meeting with the Univ. of Calif., Stanford Univ., and Univ. of Santa Clara Branches. First prize of one year's dues in the Institute was awarded to L. W. Thorpe, Univ. of Santa Clara. April 15. Att. 48.

### Saskatchewan

Loop Systems in H. T. Transmission for Urban Districts, by N. W. Dubois, Dominion Elec. Pwr., Ltd., and E. W. Bull, supt. of light and power of Regina. Feb. 5. Att. 31.

Ladies' Night. April 22. Att. 52.

### Schenectady

Seven members of the staff of the Genl. Elec. Co. spoke on the subject of noise measurement and reduction. Joint meeting with the A.S.M.E. Sec. March 3. Att. 225.

The Locomotives of the Future, by A. Lipetz, Am. Locomotive Co. Joint meeting with A.S.M.E. Sec. March 24. Att. 200.

### Seattle

Joint meeting with the Univ. of Wash. Branch, at which the following papers were presented by students: Measurement of Harmonics by Means of Vacuum Tubes, by R. M. Boyle; Magnetization Curve by Magnetic Pull Method, by M. Bouck; Velocity Aspects of the Electric Figures, by Arthur Kramer. April 19. Att. 80.

### Sharon

A Personal Tour of European Power Stations, by Philip Sporn, Am. Gas & Elec. Co. Film—"Behind the Lines." April 12. Att. 125.

### Springfield

The Earth, a Great Magnet, by Prof. S. Williams, Amherst Col. March 14. Att. 81.

Artificially Generated Sunlight, by Dr. Paul Luckenbach, Genl. Elec. Co. Election of officers: Hans Passburg, chmn.; L. C. Packer, vice-chmn.; J. J. Finn, secy.-treas. April 11. Att. 54.

### Toronto

New Utility Given Mercury Arc Rectifiers by Sectionalizing, by A. L. Atherton, Westinghouse Elec. & Mfg. Co. Joint meeting with Engineering Inst. of Canada. April 22. Att. 300.

A Trip Through the Canadian Arctic, by Lawren Harris. Illustrated. Election of officers: I. M. Maclean, chmn.; J. M. Thomson, secy.-treas. April 29. Att. 100.

### Urbana

The Institute and the Electrical Industry—What of Their Future? by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. Joint meeting with Purdue Univ. and Rose Poly. Inst. Branches. April 2. Att. 166.

### Utah

The Public Utility, by G. M. Gadsby, Utah Pwr. & Lt. Co. Dinner. March 7. Att. 37.

The Development of Utah, by A. B. Young. March 30. Att. 45.

### Vancouver

Protective Switchgear for A-C. Power Systems, by D. Robertson, Can. Genl. Elec. Co. Illus. April 4. Att. 55.

The Mercury Arc Rectifier, by L. M. Morton, Genl. Elec. Co. April 25. Att. 50.

### Worcester

Electric Heating Industry, by H. M. Chatto, Genl. Elec. Co. Feb. 29. Att. 38.

Tramways, by E. T. Reardon, Am. Steel & Wire Co. March 17. Att. 20.

Recent Development in the Application of Electric Motor Drives in the Paper, Textile, and Machine Tool Industries, by H. F. Banan and F. D. Snyder, Westinghouse Elec. & Mfg. Co. Dinner. April 14. Att. 60.

## Past Branch Meetings

### University of Akron

The Progress of Radio, by John Chenot, student; Refrigeration, by R. A. Gerber, student. Dec. 9, 1931. Att. 15.

The Zeppelin Akron, by J. C. Fessler, student; Some Applications of the Photoelectric Cell, by Sol. Leiboritz, student. Demonstrations. March 9. Att. 11.

Prof. J. T. Walther, counselor, outlined the activities of the A.I.E.E. Frank Marcinkoski, chmn., reported on the student convention held at Haverford Col. April 22. Att. 10.

### Alabama Polytechnic Institute

Ornamental Forestry, by Mr. Evans, Alabama Pwr. Co. April 14. Att. 19.

The Value of Belonging to the A.I.E.E., by Prof. W. W. Hill, counselor. April 21. Att. 10.

Muscle Shoals, by R. Roberts. April 28. Att. 7.

Entertainment. May 5. Att. 42.

### University of Alabama

Business meeting. April 11. Att. 24.

Principle of Uncertainty, by Dr. B. A. Wooten. Election of officers: W. R. Purcell, chmn.; John Marshall, vice-pres.; E. L. Appoloni, secy.; J. Del Coliano, treas. April 25. Att. 45.

### University of Arizona

The Recording of Sound for Sound Pictures, by J. W. Jones, student. April 1. Att. 9.

The Reproduction of Sound in Sound Pictures, by H. E. Stewart, student. April 8. Att. 7.

Speed Control by Electron Tubes of Sound Picture Projectors, by R. H. Carson, student; Some Recent Experiments in Electron Physics, by Dr. E. H. Warner. Dinner. April 15. Att. 7.

### University of Arkansas

Electrical Distribution, by H. H. Lewis, student; Welding Generators, by L. F. Williams, student. Election of officers: L. C. Wasson, chmn.; R. B. Stone, vice-chmn.; C. L. Mowery, secy.; P. H. Johnson, treas. April 11. Att. 24.

### Bucknell University

Discussion. March 21. Att. 10.

All Electric Ship, by John Barton, student. H. Smithgall, Jr., elected secy.-treas., and J. A. Everitt, elected vice-pres. April 18. Att. 18.

Modulation Measurements by Oscillograph on Radio Station WPSC, by D. H. Smith and R. F. Carlson, Penn. State Col.; Graphical Solutions of Alternating Currents, by James Dobbie, Bucknell Univ. Joint meeting with Penn. State Col. April 27. Att. 49.

### California Institute of Technology

Some Recent Developments in Telephone Communication, by C. A. Wells, Southern Calif. Edison Co., Ltd. April 15. Att. 18.

### University of California

Engineering Opportunities in Foreign Countries, by R. W. Shoemaker. C. Van Camp, student, described the work being done in the physics dept. with high velocity protons. April 12. Att. 30.

### Carnegie Institute of Technology

Smoker. April 22. Att. 59.

The Work of a Control Engineer, by A. C. Dyer, Elec. Controller & Mfg. Co. Election of officers: W. Uffelman, chmn.; R. S. Fish, vice-chmn.; Wm. H. Nichols, secy.; S. J. Hyle, treas. May 4. Att. 20.

### Case School of Applied Science

Election of officers: N. T. Dennis, vice-pres.; W. C. Jenner, secy.; C. L. Fantur, treas. May 4. Att. 40.

### Catholic University of America

Problems Confronting the Engineers of Modern Telephone Companies, by Francis Wheeler, Chesapeake & Potomac Tel. Co. April 13. Att. 40.

### Clarkson College of Technology

Demonstrations and luncheon. Guests of the Science Club of St. Lawrence Univ. April 5. Att. 25.

Motion pictures. April 18. Att. 47.

Election of officers: B. Zimbee, chmn.; J. Sullivan, secy.; W. Harper, treas. April 28. Att. 27.

### Clemson Agricultural College

Engineering Features of Three Power Locomotives, by J. L. O. Foster, student; Steam vs. Electricity for Driving Power Station Auxiliaries, by H. A. Clayton, student; The Future Engineer, by S. E. Lowry, student. Feb. 18. Att. 28.

Stability Experiences With Conowingo Hydro Plant, by A. E. McCall, student; Tape Armored Telephone Toll Cable, by T. M. Watson, student; A Corona Tube Voltage Regulator, by H. M. Rogers, student. March 17. Att. 17.

Interconnections of Electric Power Systems, by W. W. Dickson, student; A Quiet Power House, by F. H. Williams, student; A Portable Radio Beacon, by W. H. Gist, student. April 7. Att. 30.

### University of Colorado

Election of officers: S. W. Hannah, pres.; A. E. Logan, vice-pres.; J. S. Kenyon, secy.; E. C. Sparrow, treas. April 6. Att. 20.

Prof. M. S. Coover outlined the activities at the summer convention held last June. April 20. Att. 25.

The Application of Electricity to Mining on the Witwatersrand, by E. A. Faber; A Study of Rectifier Filter Systems Used in Communication Systems, by F. Wickenkamp, Univ. of Wyoming; Applications of Non-Linear Circuits to Electrical Engineering Problems, by F. W. Cooper and T. M. Austin, Univ. of Colo.; Magnetism and Diamagnetism, by E. R. Gertner and E. Olcott, Univ. of Denver. Joint meeting with the Denver Sec., and students of Univ. of Denver, Colo. School of Mines, Colo. Agri. Col., and Univ. of Wyoming. April 29. Att. 65.

**University of Denver**

Experiences as a Copper Metallurgist in Chile, by Carol Craven. Illus. April 8. Att. 28.

Annual conference on student activities of District No. 6. April 15–16.

**Drexel Institute**

Students attended the student Branch convention held at Haverford Col. March 14.

Insulator String Potentiometers, by A. F. Werner, student. March 16. Att. 17.

**Duke University**

History of Electricity, by T. Finger, student. April 28. Att. 13.

**University of Florida**

Problems Facing a Young Engineer and the Qualifications He Can Offer, by Mr. Garlington, Florida Pwr. Corp. April 20. Att. 55.

Election of officers: G. W. Hostettler, chmn.; J. E. Caraballo, vice-chmn.; E. A. Barnes, secy.-treas. May 2. Att. 15.

**Georgia School of Technology**

Inspection trip through the Southern Bell Tel. & Tel. Co. April 19. Att. 52.

**Harvard University**

Audible Light, by J. B. Taylor, Genl. Elec. Co. April 18. Att. 350.

**University of Idaho**

Banquet at which Prof. R. H. Hull gave a talk on electric railways. Nov. 24, 1931. Att. 21.

Banquet and talk on electric refrigeration. Dec. 16. Att. 26.

Some Developments in Talking Pictures, by K. P. Kenworthy, Univ. of Idaho; The Calibration of a Dynatron Oscillator From Broadcast Harmonics, by Melvin Herr, Wash. State Col.; Power System Frequency Control, by Clarence Cannon, Wash. Water Pwr. Co. Joint meeting with Spokane Sec. and Wash. State Col. Branch. March 25. Att. 65.

Stocks and Bonds, by Dean Farmer. April 19. Att. 18.

**University of Illinois**

Electrical engineering show. March 31–April 1–2.

Business meeting. April 13. Att. 20.

The Manufacture of Impregnated Paper Cables, by R. J. Wiseman, Okonite Callender Cable Co. April 27. Att. 175.

Muscle Shoals, by D. B. Allabough, student. May 3. Att. 25.

**Iowa State College**

The Electrical Industry of Today, by Dr. C. E. Skinner, pres. A.I.E.E., asst. director of engg., Westinghouse Elec. & Mfg. Co. March 24. Att. 160.

Banquet. April 15. Att. 170.

**University of Iowa**

Improvement of the Upper Mississippi River and Its Relation to Transportation, by Col. G. E. Edgerton. April 13. Att. 124.

Thyratron Tubes and Their Uses, by L. F. Balluff, student; Electrostatic and Magnetic Systems of Units, by J. E. Weyland, student. April 20. Att. 35.

Mr. Fortier, Northwestern Bell Tel. Co., gave a demonstration of the dial telephone system. April 27. Att. 44.

Synchronous Motors and Their Adaptability, by C. A. Bartholow, student; New Type of Hoist and Crane, by L. E. Travis, student. May 4. Att. 31.

**Kansas State College**

The Telephone as a Business, by Bob Gray, United Tel. Co. April 7. Att. 60.

**University of Kansas**

Banquet. April 8. Att. 140.

Television, by C. B. Brown, First Natl. Television, Inc. April 14. Att. 46.

Characteristics of Transformer Oil, by L. Sharp and J. D. Swafford, Univ. of Kansas; Russia, by J. C. Bradley, Kansas State Col.; Quality Comparison Between Problems in Engineering and Problems in Psychology, by Prof. R. H. Wheeler, Univ. of Kansas; Application of Weston Photronic Cell to Sound on Film Reproduction, by L. Farber and H. Lanning, Univ. of Kansas. Joint meeting with Kansas St. Col. Branch. May 5. Att. 100.

**University of Kentucky**

A Brief Study of the Vacuum Tube, by W. A. Hunter, student. Feb. 10. Att. 40.

The Mercury Arc Rectifier, by Prof. E. A. Bureau. March 23. Att. 36.

**Lafayette College**

Prof. L. J. Conover nominated for counselor. April 29. Att. 20.

Armature Windings, by K. T. Sutton, student; The History, Types, and Applications of the Photoelectric Cell, by M. Ziev, student. May 5. Att. 20.

**Lehigh University**

Mercury Vapor Rectifiers, by G. M. Kaleda, student; Direct Current Transmission, by Prof. S. S. Seyfert. Election of officers: B. D. Beach, pres.; C. W. Cooper, vice-pres.; Wm. D. Hickman, secy.; J. R. Fritz, treas. May 5. Att. 30.

**Lewis Institute**

Romance of Metals and Metal Separation, by Dr. P. B. Woodworth. May 5. Att. 185.

**University of Louisville**

Phase Advancers, by E. B. Wagner, student; Advances in Railroad Electrification—Especially European, by Mr. Kimball, student. April 22. Att. 14.

**University of Maine**

Electric Transportation, by L. Randall; Control Devices, by R. C. Brooks; Research and X-Ray Apparatus, by H. Poland; Radio, by B. Wood; Lighting, by E. Adams; Switchgear, by W. S. Davis; Marine Equipment, by L. Barrett; all students. April 14. Att. 15.

Election of officers: J. P. Gonzals, chmn.; Gerald Frost, vice-chmn.; John P. Scott, secy.; F. E. Neal, treas. April 26. Att. 9.

**Marquette University**

Election of officers: H. A. Koepp, chmn.; C. M. Warver, secy. April 7. Att. 36.

Business meeting. April 26.

**Michigan College of Mining and Technology**

Electro-Metallurgy, by F. Tolonen. Film—"Construction of Welded Pipe." April 8. Att. 15.

**Michigan State College**

Election of officers: W. C. Wright, chmn.; G. H. Kempfer, vice-chmn.; M. L. Johnson, secy. April 26. Att. 26.

**University of Michigan**

The Job Ahead, by T. N. Lacy, Mich. Bell Tel. Co., vice-pres. A.I.E.E.; Benjamin Franklin, by Prof. B. F. Bailey; The Wind Line Investigation, by Prof. W. G. Dow. Dinner. Inspection trips. Joint meeting with students of Detroit Inst. of Tech., Michigan St. Col., and Univ. of Detroit. April 28. Att. 170.

**School of Engineering of Milwaukee**

The Value of Research in Engineering, by H. L. Greusel, student; Cathode Ray Oscillograph, by L. J. Killian and E. S. Priem, students. Demonstration. April 13. Att. 84.

**University of Minnesota**

Discussion and motion pictures. April 5. Att. 18.

Inspection trip. April 21. Att. 95.

**Missouri School of Mines and Metallurgy**

Motion pictures. April 15. Att. 145.

**Montana State College**

Organization and Duties of the A.I.E.E., by Dean H. V. Carpenter, State Col. of Wash., vice-pres. A.I.E.E. Luncheon. Feb. 25. Att. 105.

New Types of Photoelectric Cells, by M. T. Severud, student; Communication With Light, by J. O. Laird, Student; Flathead Power Development at Polson, by E. Rothfus, student. Rudolph Stoken elected chmn. March 3. Att. 93.

From Apprentice Boy to Immortal, by J. Norlin; Effects of Ultra-Violet Radiation Upon the Eye, by R. Wyman; The Telephone Spans the Pacific, by C. Anderson; Insulation Materials, by H. A. Beck; 1931 Accomplishments in Telephone Field, by E. Blanchard; Electrical Apparatus for Trolley Buses, by D. A. Nauck; all students. April 14. Att. 82.

Guiding Planes by Radio, by V. Bauer; Distributing Programs in the Waldorf-Astoria, by J. W. Cromer; Automatic Voltage Regulation for Master Oscillator, by R. V. Dean; Cable Service Uninterrupted Though Channel Is Dredged, by L. Eisele; Street Lighting at Intersections, by M. Hilden; Electric Drive for Plant Auxiliaries, by J. G. Lightfoot; all students. March 31. Att. 86.

Operating Economies of Diesel Electric Locomotives, by C. L. Grebe; "Dead Spots" and How to Cure Them in Receivers, by J. D. Mathews; Interconnection of Electric Power Systems, by E. Rothfus; New Parking Device, by C. Schmitz; Some History of the Modern Telephone, by R. Stokan; all students. Victor Bauer elected secy.-treas. and J. Lightfoot elected vice-chmn. April 18. Att. 87.

The Boulder Dam Project, by L. Estey; D-C. Electric Coil Turn Counter, by E. Fisher; Electric Hotbeds, by V. Hankins; The Reliability of the Electron Tubes in Electric Service, by C. Hanson; all students. April 21. Att. 80.

Synchronous Electric Time Service, by R. Macdonald; Why Do Power Companies Plant Trees? by E. Dolum; Electrical Cooking Demonstrations, by P. B. McAdam; The Photomic Cell, by J. Joyce; Easy to Test Ground Circuit, by G. Misevic; Storage Battery Trucks for Short Haul Transportation, by E. Hughes; all students. May 5. Att. 83.

**University of Nebraska**

Discussion and demonstrations on transients, by Prof. L. A. Bingham and Mr. Bollman. April 27. Att. 43.

**Newark College of Engineering**

Welding, by S. Fishman. Election of officers: J. G. Woehling, pres.; A. E. Day, vice-pres.; L. Kufyniak, treas. April 18. Att. 25.

**University of New Mexico**

The X-Ray and Its Development, by Harold Deck, Genl. Elec. Co. May 5. Att. 25.

**New York University**

Election of officers: Wm. J. Sutton, chmn.; C. E. Hutchinson, secy. April 19. Att. 16.

**North Carolina State College**

Election of officers: L. G. Atkinson, chmn.; W. C. Cheatham, vice-chmn.; Joseph Salem, secy.-treas. April 19. Att. 31.

Diesel Engine Features, by Prof. W. J. Dana; Recent Electrical Inventions, by C. M. Smith, student. May 3. Att. 16.

**University of North Carolina**

Election of officers: F. S. Black, chmn.; G. R. Mamin, vice-chmn.; G. E. Hunter, secy.; T. C. Evans, Jr., treas. New Corpuscular Theory of Radiant Energy (or Light), by Dr. E. K. Plyler. May 3. Att. 60.

**North Dakota State College**

Election of officers: L. Schweha, chmn.; R. Netherland, vice-chmn.; Vance Schneider, secy.-treas. April 9. Att. 23.

**University of North Dakota**

Radio Receivers, Advantages of the Superheterodyne, by A. Stratmoen, student; Ultra High Frequency Radio, by R. C. Moore, student. April 13. Att. 15.

**University of Notre Dame**

New Developments in Telephony, by J. A. Barkson, Amer. Tel. & Tel. Co. Joint meeting with Engrs.' Club. April 4. Att. 129.

Electrons at Work and at Play, by Dr. Phillip Thomas, Westinghouse Elec. & Mfg. Co. April 12. Att. 550.

Radio in General, by P. A. Darmody, student; Standard Dielectric Test for Sheet Insulating Materials, by R. V. Bugni, student; V. E. Plante, Allis-Chalmers Mfg. Co., gave a talk on synchronous condensers and synchronous machines in general. Mr. Scanlon, student, presented the usual engineering digest. April 18. Att. 56.

**Ohio Northern University**

Election of officers: Donald Pees, pres.; Bernard Hauber, vice-pres.; Edgar Wagner, secy.; C. Williams, treas. April 7. Att. 26.

**Ohio State University**

Discussion. April 6. Att. 16.

The Electric Shock, by Dr. W. B. Kouwenhoven, Johns Hopkins Univ., vice-pres. A.I.E.E. Joint meeting with Columbus Sec. April 22. Att. 36.

**Ohio University**

The Use of the F-P54 Pliotron in the Measurement of X-Ray Absorption Coefficients, by J. E. Edwards, student. April 20. Att. 12.

**Oklahoma A. & M. College**

Manufacture and Use of Metallic Diamonds, by Guy Keiser, student; Gyroscopic Balance for Large Ships, by P. Bobo, student. April 11. Att. 15.

Some Aspects of Lighting, by T. Hutchinson, student; Mercury Arc Jet Rectifiers, by Lynn Cox, student. Election of officers: William Trimble, chmn.; J. R. Hollis, vice-chmn.; F. Zook, secy. April 26. Att. 20.

**University of Oklahoma**

Discussion. Feb. 18. Att. 20.

Major Developments of Radio, Particularly Its Application to Aviation, by Prof. Farrar. March 17. Att. 17.

Short Cut Calculation on the Parallel Surface, by H. Moody, student. April 14. Att. 17.

**Oregon State College**

Recent Trends in Electric Apparatus Developments, by A. W. Copley, Westinghouse Elec. & Mfg. Co., vice-pres. A.I.E.E. Hoover Dam, by C. F. Swigert, Pacific Bridge Co. April 11. Att. 70.

**Pennsylvania State College**

Fundamentals of Television, by Prof. E. B. Stabely. Demonstrations. April 15. Att. 106.

**Pratt Institute**

Step by Step Machine Switching Dial Telephone Equipment, by F. J. Skerritt, student; Panel Switching for Automatic Telephone Systems, by E. F. Zawachi, student; Operation of Selector Switch as Used in Step by Step Machine Switching Dial Telephone Equipment, by K. D. Porter, student; Electrical Equipment in an Industrial Plant, by A. Tiffany, student. April 14. Att. 25.

**Purdue University**

Effects of Frequency in Communication, by J. L. Wayne, Indiana Bell Tel. Co. April 12. Att. 45.

Iron—Nickel Alloys, by Dr. M. A. Hunter. March 15. Att. 50.

**Rhode Island State College**

After Graduation, What? by G. B. Nichols. April 14. Att. 52.

B. G. Lamme, by J. Costanza, student; C. P. Steinmetz, by Wm. Daly, student. April 21. Att. 10.

**Rice Institute**

Discussion of plans for engineers' show. March 23. Att. 27.

Discussion. April 20. Att. 21.

**Rutgers University**

An Investigation of Leakage Flux of Transformers, by F. P. Fisher, student. April 12. Att. 14.

**University of Santa Clara**

Business meeting. March 18. Att. 39.

Inspection trip. April 7. Att. 49.

Joint meeting with San Francisco Sec., and Univ. of Calif. and Stanford Univ. Branches. (See report under "Past Section Meetings.")

Election of officers: J. Russell, chmn.; J. A. O'Neil, vice-chmn.; M. Hermes, secy.-treas. May 2. Att. 9.

**University of South Carolina**

Election of officers: A. R. Urquhart, chmn.; H. G. Smith, Jr., vice-chmn.; E. C. Salley, secy.-treas. March 3. Att. 34.

Oil Electric Car in Mixed Train Service, by D. J. Delk, student; Latest Miracles of the X-Ray, by H. Howard, student; Water for Chicago's Growing Populace, by J. J. Duffie, student. April 14. Att. 33.

Relay Control Equipment at Saluda Dam, by E. P. Miller, Associated Gas & Elec. Co. April 21. Att. 101.

Inspection trip to the Saluda Dam. April 28. Att. 40.

**South Dakota State School of Mines**

Harold Hayes, student, outlined his experiences while employed by the Northwestern Bell Tel. Co. Rex Tario, student, described the inspection trip through the Homestake Mine. April 12. Att. 22.

Harold Fry, chmn., gave a résumé of the conference on student activities of District No. 6, held in Denver. April 19. Att. 40.

**University of South Dakota**

Election of officers: L. Johnson, chmn.; W. Houck, vice-chmn.; N. Larson, secy.-treas. April 11. Att. 10.

**University of Southern California**

Discussion. April 6. Att. 18.

Beach party. April 20. Att. 84.

Sound Recording Process, by Mr. Cummings, United Artists Film Corp. April 27. Att. 22.

**Southern Methodist University**

Thyratron Tubes, by J. V. Melton, student; Deion Circuit Breakers, by J. W. Emery, student; Recent Developments in Radio Tubes, by D. Ramsey and J. N. Walker, students. Jan. 8. Att. 80.

Engineers Day. Over 2,000 visitors. March 18.

Prequalification and the Lowest Responsible Bidder, by J. Wallace Emery, student; Procedure and Details of Turbine Overhaul, by E. W. Garrett, student. April 5. Att. 18.

**Stevens Institute of Technology**

Yacht Design, by Warren Riker, student. April 1. Att. 30.

The Importance of Mathematics, by Prof. R. F. Deimel. Luncheon. April 12. Att. 35.

Smoker. What an Engineer Should Know About Patents and the U. S. Patent System, by W. H. Taylor, Jr., Pennis, Davis, Marvin & Edwards. Films—"Conquest of the Cascades" and "The Construction of Small D-C. Motors." Photoelectric Cells, by Dr. Harvey C. Rentschler, Westinghouse Lamp Works. April 15. Att. 100.

**Syracuse University**

Electrical Discoveries and Experiments Leading to the Discovery of Radium, by H. E. Coswell, student; Theory of the Mercury Arc Rectifier, by E. Murphy, student. April 15. Att. 21.

History and Development of Electric Refrigeration, by J. W. Truran, student. April 22. Att. 21.

Inspection trip to the Solvay substation. April 25. Att. 21.

Theater Lighting, Pre-Set Boards, by T. J. Kelly, student. April 29. Att. 20.

**University of Tennessee**

Discussion. Jan. 14. Att. 34.

Election of officers: M. G. Toole, chmn.; L. G. Cockrill, vice-chmn.; H. H. Gnuse, Jr., secy.-treas. March 31. Att. 31.

Advantages of the A.I.E.E., by Prof. J. G. Tarboux, counselor. April 13. Att. 62.

**Texas A. & M. College**

The Design of High Voltage Lines Against Lighting Surges, by A. O. Austin, Ohio Brass Co. Talk by Col. H. S. Crocker, pres. A.S.C.E. April 14. Att. 36.

**University of Texas**

Development in the Electrical Industry in 1931, by W. D. Clayton and H. F. Allen, both of the Genl. Elec. Co. March 23. Att. 63.

Insulators, by A. O. Austin, Ohio Brass Co. April 19. Att. 62.

The Development of Public Utilities, by David Laves. April 28. Att. 10.

**University of Utah**

Cutler Dam Power Plant, by S. Kettleman, Utah Pwr. & Lt. Co. Election of officers: Frank Carman, chmn.; G. E. Bossard, vice-chmn.; Simon Ramo, secy.-treas. April 27. Att. 30.

**University of Vermont**

The Magnetic Properties of Compressed Powdered Iron, by F. P. Kenyon, student. Hydrogenized Iron, by Prof. Buchanan. April 11. Att. 18.

**Virginia Military Institute**

The Development of Gaseous Tube Lighting, by H. J. Geiger; The Magnetic Compass, by J. H. Carrico; The Motive Power for Suburban Electric Lines, by W. C. Landis; Vacuum Tubes in Industry, by J. T. Meek; The Improvements Around Niagara Falls, by S. J. Mergenhagen; all students. April 9. Att. 51.

What Big Business Expects of the College Man, by R. C. Saunders; Teletype Communication, by P. C. Wooters; Plane Dispatching on the Big Airlines, by W. W. Holt; Electricity in Advertising, by T. L. Moore; Visit Conowingo, by E. R. Trapnell; all students. March 19. Att. 74.

The Engineer and His Responsibility as a Citizen, by L. Hilliard; Torque-Angle Characteristics of Synchronous Machines Following System Disturbance, by S. A. Singleton; Trouble Shooting on a Highline, by H. A. Longino; U. S. Navy Requirements for Diesel Engines, by W. M. Cummings; Underworld Broadcasting Stations, by L. DeCamps; all students. May 2. Att. 43.

**Virginia Polytechnic Institute**

Increasing Brush Capacity, by G. R. Elder; A Study of Lighting on Transmission Lines, by E. W. Whitmer; The Operation of Mercury Vapor Turbines, by N. L. Gregg; The Point-O-Lite, by A. R. Neal; Hydroelectric Plant at Lynchburg, Va., by M. L. Simpson; all students. April 21. Att. 27.

Election of officers: P. H. Cross, chmn.; N. L. Gregg, vice-chmn.; W. L. Young, secy. May 5. Att. 43.

**State College of Washington**

The Electrification of the Great Northern Railway Through the Cascade Tunnel, by G. H. Walker, Great Northern Railway. Film—"The Conquest of the Cascades." April 15. Att. 130.

Problems Arising With the Commercial Engineer, by B. H. Collison, Pacific Tel. & Tel. Co. April 19. Att. 52.

**University of Washington**

The Power Possibilities of the Columbia River, by Eugene I. Pease. April 18. Att. 22.

Commercial Uses of the Vacuum Tube, by J. T. Copley, Genl. Elec. Co. April 20. Att. 79.

Glenn Parker, U. S. Geological Survey, spoke on water power sites and stream gaging. May 3. Att. 128.

**Washington University**

Electrons at Work and at Play, by Dr. Phillips Thomas, Westinghouse Elec. & Mfg. Co. Demonstrations. May 1. Att. 250.

**West Virginia University**

Telephone, by R. W. Blair; Powdered Fuel and Ash Precipitation, by P. Skaff; Springdale Power Plant, by J. L. Simpson; Westinghouse High Tension Laboratory, by M. L. Sprigg; Pittsburgh Equitable Meter Co., by J. Kayuha; Colfax Power Plant, by C. J. DeLancy; Pittsburgh Telephone Exchange, by E. L. Engle; Electrical Equipment of the Carnegie Steel Co., by A. W. Friend; Pittsburgh Equitable Meter Co., by W. C. McMillion; all students. April 12. Att. 29.

Westinghouse Radio Station KDKA, by D. C. Kennedy; Electrical Equipment of the Carnegie Steel Co., by H. V. Locker; Elevator Hoisting Equipment and Control, by E. J. Williams; Direct Strokes in Transmission Lines, by J. E. Wallace; Mesta Machine Co., by V. S. Monteith; Westinghouse Elec. & Mfg. Co., by P. Vannoy; High Tension Testing Laboratory, by L. Kirwin; Springdale Power Plant, by C. J. McCormick; all students. April 19. Att. 29.

**University of Wyoming**

Labor, by E. K. Nelson, city engr. Joint meeting with A.S.M.E. Branch. April 12. Att. 11.

## Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the address as it now appears on the Institute records. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Andreae, S. C., 2224 Charnwood Ave., Los Angeles, Calif.
Archbold, Earl J., Box 2641, Birmingham, Ala.
Brentnall, E. L., W. R. Hendrey Co., Hoge Bldg., Seattle, Wash.
Bugg, Vernon, 736 Transportation Bldg., Washington, D. C.
Grable, Joseph P., Genl. Cable Corp., Ft. Wayne, Ind.
Iwe, Halfdan G., 229 Ovington Ave., Bklyn., N. Y.

Miyamoto, Tatsuo C., 1330-4th St., Sacramento, Calif.
Palit, Hari-Charan, 151 Ganesh Mohal, Benares City, India.
Rogge, C. A., Consumers Pwr. Bldg., Jackson, Mich.
Scanlon, D. L., KFPW, Ft. Smith, Ark.
Schwartz, Carl, 410 Cathedral Pkwy., N. Y. City.
Thomas, Earl Mead, Intl. Genl. Elec. Co., Schenectady, N. Y.
Titland, Trygve T., 1019 Stanton Ave., Elizabeth, N. J.
Van Ness, L. G., 2105–6 Sterick Bldg., Memphis, Tenn.
Vetri, L., Western Elec. Co., Inc., 100 Central Ave., Kearny, N. J.

# Employment Notes

## Of the Engineering Societies Employment Service

## Positions Available

LARGE ELEC. AND MECH. MFG. CONCERN in Europe requires an executive designing engr. for their oil switch division. Fully trained E.E. of Swiss origin, thoroughly experienced in the modern design and construction of high tension overhead equipment, especially oil switches. Must have executive ability and speak German fluently. Apply by letter stating complete information as to age, education, experience, references, salary, etc. W-3754-CS.

A COMPANY MFG. a diversified line of elec. apparatus wishes to fill the position of supt. in a medium size plant in the Middle West. Applicant must be a graduate of a tech. univ., have a good personality, executive ability, and a knowledge of modern mfg. methods and equipment, supported by 10 to 20 yr. actual experience. Apply only by letter. W-3780-R-501-C.

## Men Available

### Agents' Representatives

MFRS'. AGT. OR SALES ENGR., sales connection desired, 42. Twelve yr. engg., 8 yr. sales experience. Tech. col. education and also war training at naval academy. Willing to go anywhere—New England States preferred. D-783.

### Construction

ELEC. CONSTRUCTION ENGR., 33; 10 yr. practical experience in elec. construction work on new buildings. Familiar with all branches of electrical contracting, including estimating, field engg., and purchasing. Has been in complete charge of elec. work in various large building projects in New York City. A-850.

### Design and Development

E.E. GRAD., 31, single, 8 yr. experience in design of regulators and transformers. Desires position with utility or mfg. concern. Location, immaterial. Available on short notice. Excellent references. D-774.

ELEC. DESIGN ENGR., A.B., E.E., 33, married, Westinghouse elec. design school. Nine yr. responsible experience in design of d-c. motors and generators; also successful development work. Expert on commutation. Desires design work or teaching. Available on short notice. Location, immaterial. C-201.

E.E. GRAD., 28, married, 6 yr. experience in ry. signal engg. steam and elec. rys. Familiar with circuit design, estimating, installation, and maintenance of a-c. and d-c. signaling equipment. Also 1 yr. experience on steam r.r. electrification. Willing to go anywhere. C-6914.

ELEC. AND MECH. DESIGN ENGR., 41, 16 yr. experience in design and development of elec. apparatus for large quantity production; 5 yr. specializing in cost reduction design on apparatus in highly competitive field. Experience covers control apparatus, radio, refrigeration, and talking pictures. Best of references. East preferred. Available immediately. C-4977.

ELEC. DESIGNER, col. grad., 15 yr. engg. experience, comprehensive knowledge design of generating plant and substation. Expert switchboard engr., including diagrams, control, relays, etc. Desires position with utility. Available immediately. Location, immaterial. D-482.

ELEC. DESIGNER ENGR., 30, single, 10 yr. experience in design of complete elec. systems, substations, hydro-stations, industrial maintenance. Responsible, capable asst. to engr. Educated in Sweden, B.S. in E.E., American citizen, linguist. Location, immaterial. D-914.

### Executives

MEMBER, 42. Extensive and diversified executive experience here and abroad. Communications engg.; utilities; corporate organization and mgmt.; personnel; sales. Contacts everywhere. Unusual and easily verified record of achievement. Qualified as a corporate secy., treas., sales engr., or as asst. to busy executive. D-730.

ELEC.-MECH. ENGR., 36, 6 years' consulting experience with large western firm, architects and engrs. Contact man. Entire charge large projects in central station and industrial field. Seven yr. design and construction large eastern utility. Registered New York. Speaks French. Will consider anything anywhere. Available May 15. D-52.

E.E., 37, married, 12 yr. experience in design of substations, elec. installation of ships, statistics, valuation, estimates. Best references from large firms in Germany and U.S. Prefer to represent American firm in Germany, Austria, or Switzerland. D-812.

E.E., grad., 42, 5 yr. supervision elec. maintenance r.r. Six yr. head elec. and mech. maintenance group of coal mines. Eight yr. assoc. editor coal mining magazine, experienced equipment photography, wide acquaintance, numerous excellent references. B-7563.

SUPT. of distribution, grad. Lowell Inst. Sch., auspices Mass. Inst. of Tech., elec., industrial mgmt. courses, 44, married. Twenty yr. elec. utility operating experience, engg., instruction, operation, maintenance of distribution, transmission lines, substations, transportation, first aid, and educational work. Has sufficient utility operating experience to qualify for position of supt. C-8411.

E.E., married, E.E., M.E. Twenty-two yr. experience, designing, construction pwr. plants, substations, transmission, distribution systems, industrial plants. Three yr. charge purchasing engineering equipment, foreign interests. Three yr. executive experience charge engg. dept. large utility syndicate. English, German, Russian, Armenian languages. Available immediately. D-84.

E.E. GRAD., Univ. of Wis., 33, single, 3 yr. Westinghouse Test, 7 yr. supervising pwr. plants, substations, transmission line construction. Four yr. engg. inspection, purchasing, expediting, tracing, res. engr., and writing specifications. Excellent reference. Can handle responsibility. Wants connection, utility, holding company, contractor, or mfr. Available immediately. Location, immaterial. B-9661.

E.E., 40. Eighteen yr. operating and engg. experience with large pwr. companies and in central holding company's engg. dept. Desires position as chief engr. small or moderate sized company or as asst. for large company. C-9291.

E.E. GRAD., 32, single, valuable experience in construction and E.E. dept. of large utility and as asst. genl. mgr. with mfr.; also selling experience. Glad to furnish references. Very willing to travel over large territory. Location, immaterial. D-745.

GRAD. ENGR., American, 27 yr. experience in design, erection, operation, and maintenance of all kinds of machy. Recently in charge of 35,000-hp. elec. installation. Expert on central station rates and contracts. Small salary acceptable in order to secure employment. C-6200.

E.E., E.E. degree. Fourteen yr. experience utilities covering valuation work, rate investigations, engg. pwr. plants, substations, transmission lines, including estimates, specifications, design. Experience covers short circuit studies, stability analysis, investigations of systems for load conditions. Desires position, holding company, operating company, or engg. firm. Available immediately. C-9570.

E.E., 40, married, 18 yr. experience utilities and industrial plants as mgr., supt., chief engr., wide experience steam, Diesel, hydro plants, manufactured gas, telephone, utility accounting. Good record, excellent references. Accept anything. Available immediately. Location, no preference. D-909–325-C-1-San Francisco.

E.E. GRAD., married, 20 yr. experience abroad and in U.S.A. estimating, designing, and inspection of elec. pwr. and light layouts, including 2 yr. charge of elec. and steam plant in iron mine, 6 yr. research and 2 yr. sales experience in lamp and metal industries. Available at once. B-9034.

EXECUTIVE. E.E., grad., married, 30 yr. experience mgr., supt., elec. engr., construction, operation, utilities. Installed steam-Diesel-hydroelectric plants. Building substations, transmission lines, distributing systems, street car network, laying underground and undersea cables. District mgr., sales representative for mfrs. of H.T. oil circuit breakers, switches, transformers. Available now. B-2388.

E.E., 30, married, 5 yr. transmission, distribution dept., utility, 2 yr. chief engr. talking moving picture company, $1\frac{1}{2}$ yr. engr., wiring specifications for architects of tel. & tel. buildings. One yr. experience making Neon tubes. Designed, made apparatus for making "structural stress" and "wind pressure" test in Empire State Bldg. C-6577.

E.E., univ. grad., pwr. experience, desires position with pwr. or mfg. company. Development work preferred but not essential. B-1923.

E.E., Univ. of Ill., 12 yr. experience in design, manufacture, and sales of elec. machinery. At present chief engr. and sales mgr. Middle West

## ENGINEERING SOCIETIES EMPLOYMENT SERVICE

57 Post St.
San Francisco

205 West Wacker Drive
Chicago

31 West 39th St.
New York

MAINTAINED by the national societies of civil, mining, mechanical, and electrical engineers, in cooperation with the Western Society of Engineers, Chicago, and the Engineers' Club of San Francisco. An inquiry addressed to any of the three offices will bring full information concerning the services of this bureau.

**Men Available.**—Brief announcements will be published without charge; repeated only upon specific request and after one month's interval. Names and records remain on file for three months; renewable upon request. Send announcements direct to Employment Service, 31 West 39th Street, New York, N. Y., to arrive not later than the fifteenth of the month.

**Opportunities.**—A weekly bulletin of engineering positions open is available to members of the cooperating societies at a subscription of $3 per quarter or $10 per annum, payable in advance.

**Voluntary Contributions.**—Members benefiting through this service are invited to assist in its furtherance by personal contributions made within 30 days after placement on the basis of 1.5 per cent of the first year's salary.

**Answers to Announcements.**—Address the key number indicated in each case and mail to the New York office, with an extra two-cent stamp enclosed for forwarding.

plant mfg. elec. motors. Can handle designing, sales, or plant operation. Available soon. Location, immaterial. C-7029.

### Inspection

ENGR.-INSPECTOR. Past 8 yr. in charge of inspection dept. of large transformer mfr. Ten yr. design experience. E.E. deg. Desires position, preferably as head of inspection dept., but will consider other lines in which transformer experience from drafting board to operation would be of value. B-2409.

### Instruction

FORMER CORNELL INSTRUCTOR IN MACHINE DESIGN for 4 yr., Allis-Chalmers designer and checker 5 yr., M.E. and E.E. deg., shop apprenticeship and miscellaneous experience. 32, single. Desires teaching or engg. opportunity. Salary open. D-122.

UNIV. GRAD., B.S. and E.E. degrees, 41. Experience Westinghouse, utilities, U. S. Government and mining companies. Six yr. asst. prof. of elec. engg. and 1 yr. acting head of elec. engg. dept., state institution. Desires position teaching elec. engg. C-5021.

E.E. GRAD., M.S. deg., 28, married. Two yr. G.E. Test and radio development lab. Three yr. as radio engr. and district service mgr. in charge of service activities in 8 states with large radio mfg. concern. One yr. teaching elec. engg. Location, U.S. Available in June. D-871.

GRAD. E.E., 27, desires position teaching mathematics, E.E. subjects, or lab. work. One yr. G.E. Test, 1 yr. design engr., 3 yr. industrial mgmt. Experienced evening school teacher. Good ability, highest references. Available June. Location, immaterial. D-920.

INSTRUCTOR, grad. E.E. with practical experience in maintenance and as sound engr. D-615.

### Junior Engineers

E.E., 25, B.S. in E.E. in 1930 from mid-western school, location does not make any difference. G. E. Test experience, and about 2 yr. of wiring and repair work. Salary second to a position. D-433.

M.E.E. deg. 1930, Rensselaer Poly. Inst., single, 24, candidate for the deg. of Doctor of E.E. this June, good scholastic record. Desires experience with any utility or mfg. concern or teaching. Salary not of primary importance, available this June. Location, any part of U.S.A. or India. D-469.

GRAD. E.E., 1931, A.B., B.S., 25, single. Substation experience while student. Eight months as draftsman on wire work involving catenary design in connection with r.r. electrification. East preferred. Available immediately. D-795.

E.E., B.S. from Ohio Northern Univ., class of 1932, 23, single and excellent physical condition; willing to work hard. Have had considerable experience as salesman. Interested in any position where an engg. knowledge is required. Excellent references. Correspondence invited. Available in June 1932. Location, immaterial. D-787.

E.E., grad. 1931, Northeastern univ., cooperative plan, 22, single. Three yr. experience test and servicing elec. equipment and motors. Desires connection with construction or utility concern. Location, immaterial. Available at once. D-849.

GRAD. E.E., 27, married. Three yr. with utility on generating and substation design and layout, including switchboard and control. Two yr. industrial pwr. application. Desires position with utility co. or mfg. concern. Location, immaterial. Available one month. D-861.

GRAD. E.E., 22, Rensselaer Poly. Inst. 1930. Member Sigma Xi. Two yr. experience in plant dept. of telegraph company. Desires position with advancement in any engg. field. Salary immaterial at start. Location, North Eastern U.S. Available at once. D-785.

B.S. in E.E. Case Sch. of Applied Science 1929, 27, married; $2\frac{3}{4}$ yr. with ry. signal company in construction, testing, inspection, drafting, circuit design, and creative advertising. Two yr. practical surveying. Thoroughly familiar with the principles of illumination. Available at once. Location, immaterial. D-870.

1931 GRAD. E.E., mid-western college, 24, single. Three yr. experience in genl. maintenance, construction, and motor testing. Location, immaterial. Available at once. D-572.

GRAD. B.A. (Physics), 1932, single, 22. Desires position in elec. industry. Office experience in maintaining charts and statistics. References. Location, South West preferred, but elsewhere considered. Available on short notice. D-822.

E.E. GRAD., 1930, Carnegie Inst. of Tech., 24, single. Laboratory experience while working way through school. Two yr. experience in teletypewriter and telephone communication. Permanent position desired. Available immediately. Location, immaterial. D-881.

B.S. IN E.E. 1932, Brown Univ., editorial and advertising experience. Industrial work preferred. Good mgr., applied psychologist. Thorough understanding of d-c. and a-c. machinery, transmission lines, auxiliary apparatus, testing, and applications. General knowledge includes economics, hydraulics structures, etc. Cultured, industrious, and clever. D-742.

POSITION DESIRED by young engr., 26, col. grad. Has had two yr. G.E. Test and 3 yr. in d-c. dept. of G.E. Company on design and cost estimating of synchronous converters. D-882.

E.E., grad., 1931, 25, single, cooperative college. Twelve months' experience as asst. in production lab. of battery mfg. concern. Six months' experience as a general draftsman. Speaking and reading knowledge of German. Desires position with a future. Location and salary secondary. Available immediately. D-534.

GRAD. E.E., 1931, U. of M., single, 22. Seven months' student sales engr., Wagner E. Test. Nine months' experience elec. maintenance and construction of industrial equipment, Ford Motor Co., six months' salesman. Desires position elec. motor industry or utility with opportunity for advancement. Location, Michigan and adjacent states preferred. Available immediately. D-719.

1931 GRAD., 28, single, 8 yr. machine shop. Wishes any kind of work or study and research to obtain master's degree. Location and salary not material. Available at once. D-916.

E.E., 28, single. Experience in general engg. and research lab. of the G.E. Also 1 yr. of G.E. Test. Desires position with a laboratory, utility, or mfg. concern. Available July 1. Location in the East. D-915.

GRAD. E.E., Columbia Univ. 6 yr. course, 1932; single, 24. Desires work with utility, r.r., mfg. concern, or construction corporation. Would like to teach E.E. subjects. Location and salary immaterial. D-893.

E.E. GRAD., 1932, 24, single. B.S. in E.E. from well-known engg. school. Good scholastic record. Four yr. mfg. experience includes timekeeping, cost work, maintenance, and assembly. Desires position with opportunity for advancement with utility, engg., or mfg. firm. Location preferred, Ohio-Pa. vicinity, but will consider others. D-908.

1931 GRAD., E.E., B.S., leading western univ., 27, single. Telephone work, machine shop apprenticeship, draftsman, and machine designer, familiar with vacuum tubes, good mathematician. Excellent scholastic record. English, German, Swedish, Finnish, and Spanish languages. Desires position with industrial firm. Location, immaterial, U.S. or abroad. Available on short notice. D-923.

1931 GRAD. in E.E., B.S. from Clemson Agri. Col., 25, single. Desires work with utility, mfg. concern, or construction corporation. Available immediately. Location, immaterial. D-400.

STUDENT, 25, single, B.E.E. '32, Univ. of Detroit, 8 yr. radio-telephone experience, $1\frac{1}{2}$ yr. of which with police dept., the rest broadcasting. Would like position with large station or chain, if possible. Location, immaterial. Holds 2nd class commercial operator's license. D-926.

### Maintenance and Operation

E.E. GRAD., 1927, married. Eight yr. steam plant operation and maintenance, and factory maintenance. Now unemployed. Location preferred, Middle West or Western. C-8522.

M.E., E.E., AND C.E., graduated Italy, 30, single. Executive experience. Desires position anywhere with utility or contractor. Three yr. varied civil engg., 2 yr. in pwr. production in steam and hydroelectric plants. Skilled in any layout, topographic, and maintenance work. D-422.

ELEC. RY. ENGR., 36, grad. E.E. Extensive experience in all phases of elec. and street ry. work including plants, substations, transmission, trolley and telephone lines, elec. locos., interurban and city cars, also lighting of steam trains, etc. Record of rapid advancement. Good organizer. Speaks Spanish. C-9557.

### Research

PHYSICIST, 33, married, grad. and post-grad. work at Harvard. Eleven yr. experience in development laboratories, mostly with vacuum tubes and Neon lamps. Good knowledge of high frequency currents and theoretical mechanics. B-8390.

### Sales

SALES MGR.-ENGR., 35, experienced capable sales contact man, desires connection as representative or mfrs. agt. with high grade company mfg. line of high or low voltage equipment for utilities or industrial plants. B-4067.

SALES ENGR., E.E. grad., 30, married, $5\frac{1}{2}$ yr. experience in utility work involving pwr. station operation and maintenance; pwr. station and substation design. Teaching experience. Fourteen months' application sales engg. experience with control mfg. concern. Desires position as salesman or application engineer. Available immediately. D-713.

MFRS. AGT. OR SALES ENGR., British engr. (American papers) mech., elec., 36, single. Thorough knowledge of several British Colonies and Spain. Six years industrial sales engr., specializing industrial heat, large western utility, desires connection American firm contemplating plant or sales office within British Empire, South America. Fluent Spanish, French. Available immediately. D-806.

E.E. GRAD., 30, family, $2\frac{1}{2}$ yr. telephone engr., 2 yr. sales mgr. for automotive jobbing house, 2 yr. field engr. for elec. light company, with a total of $2\frac{1}{2}$ yr. drafting on tool and machine design. Desires work of any kind or type paying living wages. Location, immaterial. C-951.

ELEC.-MECH. ENGR., 39, married. G.E. student course. Eighteen yr. experience sequence motor control systems, industrial engg., sales, patents, investigations and reports, machinery development. Prefers connection as industrial consultant or as sales engr. C-9552.

### Testing

GRAD. E.E., 29, single, B.S., Union College, 1929. One yr. with Underwriters' Lab., 2 yr. Otis Elevator Co., development and test dept. Familiar with all types of elevator and escalator equipment. Desires position designing and testing of industrial control equipment. Available at once. Location immaterial, preferably the South. D-558.

# Membership

## Recommended for Transfer

The board of examiners, at its meetings on the dates given recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the acting national secretary of the Institute.

### To Grade of Fellow (May 18, 1932)

Christie, Clarence V., prof. of elec. engg. and head of dept., McGill Univ., Montreal, Can.
Lovell, Wm. V. (retired), Stanford, Florida
Rees, John B., equip. and bldg. engr., Am. Tel. & Tel. Co., New York

### To Grade of Member (April 13, 1932)

Anderson, Albert S., central station dept., Genl. Elec. Co., Denver, Colo.
Anderson, Henry C., asst. engr., N. Y. & Q. Elec. Lt. & Pwr. Co., Flushing, N. Y.
Blume, Norman H., wire chief, Wisconsin Tel. Co., Madison.
Buchanan, Wm. B., testing engr., Hydroelectric Pwr. Comm. of Ont., Toronto.
Crowdes, George J., asst. elec. engr., Simplex Wire & Cable Co., Cambridge, Mass.
Grauten, S. H., acting development engr., Pub. Serv. Co. of No. Ill., Chicago.
Hayden, C. B., service engr., Pub. Serv. Comm. of Wis., Madison.
Houghton, M. G., supervisor of elec. engg., Detroit Inst. of Tech., Detroit, Mich.
Hull, R. M., division distribution engr., Pa. Pwr. & Lt. Co., Allentown.
Marconi, C. G., elec. engr., Elec. Bond & Share Co., New York.
Perreten, Arnold E., asst. elec. distribution planning engr., Pub. Serv. Co. of Colo., Denver.
Peterson, T. F., consulting cable engr., Am. Steel & Wire Co., Worcester, Mass.

Ready, Lester S., consulting engr., San Francisco, Calif.
Sealey, Wm. C., elec. engr., Allis-Chalmers Mfg. Co., Milwaukee, Wis.
Skooglund, Carl M., pwr. station design engr., West Penn Pwr. Co., Pittsburgh, Pa.
Spaulding, G. W., asst. to genl. supt., Pa. Water & Pwr. Co., Baltimore, Md.
Steinberg, Max J., elec. field engr., Brooklyn (N. Y.) Edison Co.
Stevens, Earl E., elec. testing engr., Commonwealth Edison Co., Chicago, Ill.
Weidlein, Wm. D., engr., Black & Veatch, Kansas City, Mo.
Wendell, R. B., design engr., Pub. Serv. Co. of No. Ill., Chicago.

### To Grade of Member (May 18, 1932)

Bostwick, Wm. E., inspector, Pa. R.R. Co., Altoona, Pa.
Burlingham, Kenneth R., chief electrician, Milwaukee County Institutions, Wauwatosa, Wis.
Cockburn, John M., telephone systems engg. dept., Northern Elec. Co., Montreal, Can.
Damania, Sorab B., engr.-in-charge, Ambernath Elec. Supply Serv., Ambernath, G.I.P. Ry., India
Ege, Wm. W., dist. mgr., Copperweld Steel Co., Chicago, Ill.
Ekeroth, Walter M., asst. engr., Brooklyn (N. Y.) Edison Co.
Langwig, Frank I., asst. engr., N. Y. Telephone Co., Albany
Lewis, Ephraim H., genl. mgr., Union Elec. Lt. & Pwr. Co., and St. Louis County Gas Co., Webster Groves, Mo.
Lightband, Denis A., designing elec. engr., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
Tang, Kwan Yau, prof. of elec. engg., Ohio State Univ., Columbus, Ohio
Travers, Fred H., engr., Genl. Elec. Co., Bridgeport, Conn.

## Applications for Election

Applications have been received at headquarters from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the acting national secretary before June 30, 1932.

Brainerd, J. G., Univ. of Pa., Phila.
Briggs, A. S., Jr., Phila. Elec. Co., Phila., Pa.
Campbell, F. W. (Member), Westinghouse Elec. & Mfg. Co., Cleveland, Ohio
Carlson, E. J., Univ. of Calif., Berkeley
Casavant, F. C., Syracuse (N. Y.) Lt. Co., Inc.
Coffinberry, C. M., Elec. Engg. Sales Co., Los Angeles, Calif.
Crump, L. L. (Member), James R. Kearney Corp., St. Louis, Mo.
Davidson, L. A., Okla. Gas & Elec. Co., Oklahoma City
Deming, A. F., Natl. Advisory Committee for Aeronautics, Langley Field, Va.
Harrison, E. T. G., Southwestern Bell Tel. Co., Oklahoma City, Okla.
Held, C. A. (Member), Monks & Johnson, Boston, Mass.
Henshaw, W. J., Vancouver Pwr. Co., Lake Buntzen, B. C.
Hoover, H. C., Wagner Electrical Corp., Washington, D. C.
Johnston, A. B., Southwestern Bell Tel. Co., Oklahoma City, Okla.
La Chapelle, H. C., Am. Tel. & Tel. Co., Denver, Colo.
Luckenback, C. E., York Ice Machinery Corp., York, Pa.
Mahaney, D. J., Southwestern Bell Tel. Co., Oklahoma City, Okla.
McCluskey, F. J., James R. Kearney Corp., St. Louis, Mo.
McLean, C. H., British Columbia Telephone Co., Vancouver, B. C., Can.
Parkhurst, E. T., 79 Walnut St., Somerville, Mass.
Pedersen, A. H., Automatic Temperature Control Co., Germantown, Phila., Pa.
Pendleton, V. A., Oklahoma Gas & Elec. Co., Oklahoma City
Powers, C. F., New England Pwr. Engg. & Serv. Corp., Boston, Mass.
Reese, L., Pacific Gas & Elec. Co., San Francisco, Calif.
Risen, H. J., Okla. Gas & Elec. Co., Oklahoma City
Schroeppel, H. C., Memphis Pwr. & Lt. Co., Tenn.
Todd, J. M. (Fellow), 818 Maritime Bldg., New Orleans, La.
Vance, R. L., Bell Telephone Labs., N. Y. City
Wall, W. W., Natomas Co., Natoma, Calif.
Woll, L. B., 741 Fairmount Place, N. Y. City
30 Domestic

### Foreign

Headland, H., Public Wks. Dept., Waitaki Hydro, South Island, N. Z.
Hickey, M. G., Hackbridge Elec. Construction Co., Hersham, Walton-on-Thames, Surrey, England
Sawhney, B., Associated Electrical Industries, Lahore, India
3 Foreign

# Engineering Literature

## New Books in the Societies Library

Among the new books received at the Engineering Societies Library, New York, during April are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no reponsibility for statements made in the following outlines, information for which is taken from the preface or text of the book in question.

S.A.E. HANDBOOK. Complete supplement to 1931 edition. N. Y., Society of Automotive Engrs., 1932. 125 p., illus., 7x4 in., paper, $1.00 to non-members; $.50 to members.—Instead of issuing a revised edition of the handbook, the Society has published this complete supplement. Containing all new and revised standards and recommended practises adopted since the last book appeared, with a list of canceled specifications, thus bringing the work entirely up to date.

SCHWEIZERISCHE ENERGIEWIRTSCHAFT. By M. L. Keller. Aarau (Switzerland), Verlag H. R. Sauerläander & Co., 1931. 112 p., 9x6 in., cloth, 4 Swiss Frs.—A discussion of electric power development in Switzerland, its defects, and ways to better conditions. Treated from economic and political points of view. Establishment of a special government institution is advocated, patterned on the Swiss National Bank, to which the control of power developments and electricity supplies will be delegated.

SYMPOSIUM ON EFFECT OF TEMPERATURE ON THE PROPERTIES OF METALS. Am. Soc. of Mech. Engrs., N. Y., and Am. Soc. for Test. Mtls., Phila., 1932. 829 p., illus., 9x6 in., cloth, $6.00 to non-members; $5.00 to members.—Papers (27) presented at a joint meeting of the A.S.M.E. and the A.S.T.M. in Chicago, 1931; discuss various problems related to engineering trends and requirements for metals at high and low temperatures, and the properties of metals for use at these temperatures. The book ably summarizes our present knowledge of the subject and brings up to date the records of a similar meeting in 1924. A bibliography is included.

TALKING PICTURES. By B. Brown. N. Y. & Lond., Isaac Pitman & Sons, 1931. 305 p., illus., 9x6 in., cloth, $3.00.—Origin, how it works, and the practical details of the apparatus and its operation for the modern talking picture as set forth in an interesting way in this book. Successful explanation of matters in a way can be understood without technical training, and in presenting a comprehensive view of the industry within a moderate compass.

THE TAYLOR SERIES, an introduction to the theory of functions of a complex variable. By P. Dienes. Oxford, Eng., Clarendon Press (gift of Oxford University Press, N. Y.), 1931. 552 p., 9x6 in., cloth, 30s. This scholarly introduction to the theory of functions of a complex variable adopts the way of approach by the methods of Cauchy and Weierstrass. The first seven chapters give the elements of the usual Cauchy-Weierstrass theory. The remaining seven chapters discuss and coordinate further developments of the theory by Picard, Hadamard, Mittag-Leffler, Borel, and others. There is a good bibliography.

WORKING FOR THE SOVIETS, an American Engineer in Russia. By W. A. Rukeyser. N. Y., Covici, Friede, 1932. 286 p., illus., 8x6 in., cloth, $3.00.—A first-hand description of industrial conditions, by an American mining engineer. The author's work for the Soviet government took him to the asbestos mines of western Siberia with no companions except Russians. He had unusual opportunities to know them and to learn what they thought and how they lived. He gives an interesting account of his experiences.

ADVANCING SCIENCE. By O. Lodge. N. Y., Harcourt, Brace & Co., 1932. 191 p., 8x5 in., cloth, $2.00.—This volume sketches the work of the British Association for the Advancement of Science between 1870, when Sir Oliver Lodge became a member, and 1900. A regular attendant at its annual meetings, he has vivid recollection of the great men of that period and of the outstanding events and papers of each meeting. These he describes in an interesting manner. The discovery of the electron and the beginnings of the study of ether waves are discussed.

AMERICAN ELECTRICIANS' HANDBOOK. By T. Croft. 3d ed., N. Y. & Lond., McGraw-Hill Book Co., 1932. 1051 p., 7x4 in., leath., $4.00.—This popular handbook gives the facts about apparatus, materials, installation, and operation needed by wiremen, contractors, linemen, plant superintendents, and construction engineers in their daily work. Theory is reduced to a minimum, but sufficient is given to explain the reasons for the methods recommended. The edition has been revised to conform with current practise and the latest code requirements.

BEHEMOTH, the Story of Power. By E. Hodgins and F. A. Magoun. Garden City, N. Y., Doubleday, Doran & Co., 1932. 354 p., illus., 9x6 in., cloth, $3.50.—A narrative history of power, built about personalities which have contributed to the evolution of motive machinery, and intended for the reader without technical training. The development of the steam and internal-combustion engines, of the dynamo and hydraulic turbine, is presented in broad outline from the earliest times to the present, in an unusually readable, entertaining way.

EINFÜHRUNG IN DER EBENE GETRIEBELEHRE. By T. Pöschl. Berlin, J. Springer, 1932. 127 p., 9x6 in., paper, 9.75 rm.—An elementary textbook, designed for home study and for students in engineering colleges. Graphic methods are used and a knowledge of vectorial analysis is required. The course is planned with close attention to practical needs.

HOCHFREQUENZTECHNIK IN DER LUFTFAHRT. By H. Fassbender. Berlin, J. Springer, 1932. 577 p., illus., 10x6 in., cloth, 68 rm.—Prepared for the German Aircraft Research Institute by a number of specialists, this book is intended to present a comprehensive account of the present state of radio communication with aircraft. The theoretical principles and methods of measurement first are considered; then the problems of direction finding. The apparatus used in the different flying countries is described, after which a section is devoted to radio service for flyers. Theoretical and practical aspects of the subject are discussed at some length, and bibliographies are scattered through.

ELEMENTS OF HUMAN ENGINEERING. By C. R. Gow, ed. by F. A. Magoun. N. Y., Macmillan Co., 1932. 169 p., 8x5 in., cloth, $1.60.—The second of a series of books by the professor of humanics at the Massachusetts Institute of Technology. From his broad practical experience, Professor Gow gives sensible advice to the young engineer who is beginning his career upon the cultivation of correct personal relations with superiors and subordinates and similar topics that greatly affect his success in life but are not covered in his course of study.

NACHTRAG III ZUM WERKSTOFFHANDBUCH NICHTEISENMETALLE. Berlin, Beuth-Verlag, 1932. 14 p., illus., 8x6 in., paper, 3.50 rm.—Third supplement to the Handbook of Non-Ferrous Metals. Contains new information upon torsion testing, corrosion testing, electric melting furnaces, metal coatings, and the working of pure aluminum. The material is in loose-leaf form for insertion in the handbook.

### Engineering Societies Library

29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a cooperative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

# Annual Technical Committee Reports to the Board of Directors

In accordance with Section 82 of the A.I.E.E. By-Laws, the Technical Committees of the Institute have prepared the following reports for presentation at the Summer Convention.

To accomplish a timely circulation of these committee reports throughout the membership of the Institute, ELECTRICAL ENGINEERING presents on the following 27 pages a preprint of a portion of a future issue of the quarterly TRANSACTIONS.

# Research

## ANNUAL REPORT OF THE COMMITTEE ON RESEARCH[*]

DURING the year 1931 the Committee on Research has encouraged the presentation of research papers and has reviewed many for sessions on research before the A.I.E.E. On account of the broad field which must be covered by this committee it has been impracticable to organize subcommittees under any specific classification. The burden of reviewing papers has fallen to practically all members and excellent cooperation has been obtained by correspondence and without committee meetings.

The following topics are worthy of mention to show the progress that has been made during the year. The subjects reported have all been suggested by committee members.

### PHYSICS

Dr. R. J. Van de Graaf of Princeton University and Massachusetts Institute of Technology has developed static machines of a very simple construction using endless silk belts with which he has generated as high as 1,500 kv. This work is being extended to much higher voltages.

Dr. F. Lange and A. Brasch of the University of Berlin have built a simple X-ray tube consisting of alternate rings of paper, rubber, and aluminum which they hope to operate with voltages up to 2,500 kv.

A number of developments have taken place during the year in connection with X-ray tubes and auxiliaries. Some of these are described in the January issue of the *General Electric Review*. The application of X-rays commercially has been extended during the year to the sterilization of food and food products.

Experiments have recently been made in this country on a sodium vapor lamp, originally developed in Germany. This lamp has been made possible by a new kind of glass which is not blackened by the sodium vapor. This lamp is said to be several times as efficient as the ordinary mercury or gas filled lamp.

In ferro-magnetic materials changes in magnetization do not occur instantaneously throughout the mass of the material, but start locally and are propagated with finite velocity. This was demonstrated on a large scale by K. F. Sixtus and L. Tonks and the velocity of propagation was measured in nickel-iron wires under tension. (*Physical Review*, 37, 1930, p. 1958, April 1931.)

From the Westinghouse Laboratories a new magnetic phenomenon has been reported by F. Bitter, which consists in the discovery of magnetic inhomogeneities of a definite and regular pattern in the individual crystals of ferro-magnetic materials. These are of quite a different nature, depending on the type of material. No satisfactory explanation has yet been obtained for this phenomenon.

Members of the staff of the Alabama Polytechnic Institute have announced the discovery of the last missing element No. 85.

From theoretical considerations, it was believed that atoms of hydrogen might exist which are twice as heavy as the ordinary atoms. These have now been discovered experimentally by H. C. Urey and G. M. Murphy of Columbia University and F. G. Brickweede of the Bureau of Standards.

Walter Bathe is reported by A. H. Compton to have produced gamma rays by bombarding beryllium metal with alpha rays. His experiments indicate a possible synthesis in which a heavier element, carbon, is formed and if proved correct it may greatly affect all ideas of how the solar system and our earth originated. (*Sc. News Letter*, p. 223, Nov. 21, 1931.)

Vacuum tubes are continually extending the ranges of possible electrical measurements and thereby opening new fields of physical research. L. A. DuBridge (*Physical Review*, 37, page 392, 1931) reports measurements of small currents of the order of $10^{-18}$ amperes which corresponds to six electrons per second.

Fowler (*Physical Review*, Vol. 38, page 45, 1931) has made important theoretical investigations of the photoelectric threshold values of clean metals at various temperatures.

Newton Harvey (*Jl. of General Physiology*, Vol. 15, p. 147) has demonstrated that living cells are disintegrated by ultra-sonic waves in less than $^1/_{1000}$ of a second.

R. W. G. Wyckoff (*Radiology*, Vol. 17, p. 1171, 1931) has obtained important data on the destruction of micro-organisms by X-rays and cathode rays in continuation of his previous work in this field.

Boer and Teves (*Zeitsch f. Phys.*, Vol. 73, page 192, 1931) have obtained further important results in connection with their investigation of the photoelectric properties of caesium oxide films in conjunction with halide salt layers.

Bergmann (*Zeitsch. f. Phys.*, April 1, 1931) has described an important photoelectric cell involving essentially the photoelectric properties of iron selenide.

### DIELECTRICS

The Committee on Electrical Insulation of the Division of Engineering and Industrial Research of the National Research Council reports very substantial progress in the study of dielectrics and dielectric phenomena. Its report, which summarizes a considerable number of recently presented papers, should be consulted by those interested in this subject. The following items, some of which were reported by the National Research Council, are of particular interest. Some of these results have been presented in the form of papers before the Institute.

---

[*] COMMITTEE ON RESEARCH:

L. W. Chubb, Chairman,
H. D. Arnold,
Edward Bennett,
W. G. Cady,
E. H. Colpitts,
E. C. Crittenden,
W. F. Davidson,
W. P. Dobson,
F. M. Farmer,
V. Karapetoff,
A. E. Kennelly,
J. K. McNeely,
F. W. Peek, Jr.,
H. H. Race,
C. W. Rice,
D. W. Roper,
T. Spooner,
J. B. Whitehead,
R. J. Wiseman.

A further reference which may be consulted with profit to those interested is monograph No. 5 of the American Chemical Society, by Professor C. P. Smythe of Princeton University, giving an extensive summary of the results of the work in determining molecular structure.

The following four A.I.E.E. papers from The Johns Hopkins University on this subject by Dr. Whitehead and his associates are particularly valuable, namely, on the *Conductivity of Insulating Oils, The Fundamental Properties of Impregnated Paper, Residual Air and Moisture in Impregnated Paper,* and *The Predetermination of the A-C. Characteristics of Dielectrics.* Other valuable A.I.E.E. papers on dielectrics are *Insulation Variability,* by M. C. Holmes; *On the Theory of Thermal Breakdown of Solid Dielectrics* by P. H. Moon, and another in the same field by Kenney, Luery, and Moriarty.

In one of the above mentioned papers by Whitehead and Banos there is announced a most remarkable agreement between loss, power factor, and capacity values at 60 cycles for solid and liquid dielectrics as determined experimentally and as calculated from the d-c. characteristics as obtained by the oscillograph.

By very careful distillation and purification as reported by L. A. Welo it has been possible to produce insulating oils having conductivities of $10^{-18}$ to $10^{-19}$ ohms.

The Bell Telephone Laboratories have reported very interesting results on ordinary insulation in which they point out that it is the metallic salt content of considerable solubility in water which controls the insulation or conductivity characteristics of such materials. Washing with water improves the insulation properties decidedly and improvement can be obtained by replacing the soluble salts with more insoluble salts by chemical reaction.

Work continues in an increased amount on the subject of polar molecules in dielectrics. This subject, originally considered of no practical value, is now being studied for viscous liquids and even solids, with very important results. Development of polar molecules in insulating oils gives a measure of deterioration. The work of W. N. Stoops points out the very definite correlation and the fact that the measure of the polar characteristics under accelerated test may furnish a measure of the useful life of an oil.

Dielectric losses in highly refined insulating oils at commercial frequencies and operating temperatures have been shown to result from conduction, but at high frequencies and low temperatures the major loss may be accounted for by the orientation of polar molecules. (H. H. Race, *Physical Review,* 37, p. 430–436, Feb. 1931.)

At Johns Hopkins University and the Bell Telephone Laboratories further studies on abietic acid and rosin have been made as to the part played by dipoles in the s.i.c. and loss characteristics of material over ranges of temperature and frequency. This type of work, directed toward an understanding of the mechanism of the dielectric in detail, is most important. It is interesting to note that both sets of data can be explained by the generalized theories of Schweidler and Wagner, which consider the dielectric mass as a whole, or by the dipole theory of Debye, which considers the microscopic structure, namely, the individual atoms, molecules, or ions as dipoles.

Studies of cable oil and cable conditions at a number of laboratories were reported last year, particularly on the effect of ion bombardment on oils. The necessity for a completely filled, solid, compact cable to prevent internal ionization is further shown. For example, it has been shown by the Detroit Edison Company that the power factor of an oil is directly correlated with the amount of hydrogen freed by ion bombardment. In the studies of the fundamental properties of paper, oil, and impregnated paper at Johns Hopkins University, it was found that with high grade oil the larger portion of the dielectric loss was attributable to the paper. Further, it has been shown by the Commonwealth Edison Company that tackiness of adhesion of the compound is correlated with long life of cables.

J. A. Scott of the General Electric Company has shown that oil pressures of several atmospheres applied to impregnated paper insulated cable give a decided increase in the life of the cable as measured by an endurance test.

The increased use of the oil filled type of cable and the growing use of oil for filling joints in ordinary impregnated paper insulated cable have greatly increased the importance of the integrity of the lead sheath. Several research projects dealing with lead are in progress. Work at the University of Illinois has shown that the creep of lead and several common lead alloys occurs at stresses below 200 lb. per square inch; that is, at stresses which may occur in cable sheaths during normal operation.

Researches on transmission cables show a tendency to depend on accelerated aging tests as a measure of the life quality. Both utilities and cable manufacturers are conducting researches on long lengths of impregnated paper-insulated cable to duplicate in a short time what takes place over a period of years in service. The present indications are that, by subjecting the cable to about 2.5 times normal voltage, and at the same time superposing loading cycles resulting in a maximum temperature somewhat above the limiting temperature for the cable, and by making measurements of power factor and ionization factor at suitable intervals throughout a test continuing a week or two, it is possible to predict the effect of many years of normal service on the stability of insulation.

Considerable interest is taking place as to the influence of pressure on a cable and its relationship to the migration of the oil in the cable as it goes through its temperature cycle.

The Detroit Edison Research Department reports that chemical reactions of organic compounds in electrical discharges are being studied as a part of a program of investigation of the deterioration of oil-impregnated paper insulation of high-tension cables. The results of an experimental survey covering 57 different hydrocarbons has been published (*Jour. Phys. Chem.*, 35, 3649 (1931)).

In the field of insulation, J. B. Whitehead summarizes the accomplishments for the year as follows:

This research has been characterized by a definite extension of our knowledge of the behavior of insulating liquids and its causes. This is a result largely of the development of amplifier and oscillograph methods for measuring short-time behavior of liquids when used for the impregnation of paper with the result that a much closer insight is now possible as to the origin of the properties of high-voltage impregnated paper insulation. A continuation of the accelerated life studies on laboratory samples of impregnated paper is clearing up the uncertainties heretofore existing as to the relative importance of residual air and moisture in impregnated paper. In connection with these researches, an important method of analysis of the results of a-c. measurements has been developed and its limitations explored.

### CIRCUIT INTERRUPTION

Vacuum relays developed in Germany have been introduced into this country which make use of the flexibility of glass to transmit sufficient motion to operate contacts. This is possible because of the very small contact separation necessary in a vacuum.

Slepian and Strom in an Institute paper (ELECTRICAL ENGINEERING, Dec. 1931) have given a valuable analysis of the factors which govern arc extinction in low-voltage network cables. It is shown that the gas blast, as the result of the action of the arc on cable insulating materials, is largely responsible for the clearing of faults. Data are given on the extinguishing characteristics of various types of chemical compounds.

By intensive research, the possibilities of boric acid in connection with circuit interrupting devices have been developed to a point where commercial applications are in sight. The production of water vapor from the boric acid by the action of the arc causes a powerful deionizing action. The water vapor may be condensed, thus making possible a very efficient enclosed fuse for high interrupting capacities.

### MISCELLANEOUS

H. B. Dwight has given a very useful analysis of the proximity effects in cable sheaths (A.I.E.E. TRANSACTIONS for September). This is supplementary to the formulas published by him some years ago in the *Electric Journal*.

In the same issue of the TRANSACTIONS there is a group of papers on the measurement and analysis of noise in electrical machinery which, in some aspects represents contribution of new knowledge as the direct result of careful research. The science of acoustics is becoming an important phase of electrical engineering. Since the world has become noise conscious the elimination of unnecessary noises will be only a matter of time. Some of the new portable noise analyzers which have been placed on the market this last year make the measurement of the magnitude and the analysis of noises much easier.

By studies at the Westinghouse Laboratories, of car and train models in wind tunnels, fundamental data have been obtained on the advantages of streamlining. These results will be of great value in reducing power and making possible high-speed land transportation.

R. M. Baker has discovered that the presence of small quantities of mercury vapor in a non-oxidizing atmosphere very greatly reduces the contact resistance for certain types of brushes and slip rings. This may be of some commercial value, especially where it is wished to use very high current densities. (*Elec. Journal*, February 1932).

The development of the helical groove on slip rings and commutators by G. M. Little promises to be of considerable value in connection with the problem of current collection and commutation. Field tests have shown decided improvements in brush wear, sparking and distribution of current between parallel brushes (ELECTRICAL ENGINEERING, June 1931, p. 427).

Researches on the conditions desirable for the greatest human comfort, namely, the effect of humidity, wall temperature, air flow, and ionic condition of the air, etc., have been very active during the past year. Also the usefulness of reversed refrigeration for the heating of houses and buildings is being tried out commercially in several installations. Air conditioning is apparently to become soon a very considerable industry of great importance to the electrical interests.

Very sensitive research measurements have shown that all metals flow to some extent at high temperatures and that this flow can be reduced by using proper heat treatment of certain alloys. Such studies are used as a basis for new mechanical design of high temperature steam and electrical turbines so that proper clearance will be maintained throughout long life. (Paper presented by F. P. Coffin and T. H. Swisher at the National Applied Mechanics Meeting of the American Society of Mechanical Engineers, June 15, 1931.)

In the field of radio, Bruce's work on directive short wave antennas is of importance.

There are two recent developments in piezo-electricity worthy of note. Thin plates of tourmalin have, within recent months, shown themselves to be excellent piezo-oscillators, particularly for very short waves down to about two meters wavelength. An interesting circumstance in this connection is that, although tourmalin was one of the very first piezo-electric crystals to be studied, nevertheless the practical applications are of very recent date. Another recent application of piezo-electric crystals is their use in filter circuits of very high selectivity.

The researches on the fundamental electrical units which have been under way at the Bureau of Standards for several years have reached a stage such that preliminary values can be given, subject to some minor corrections. The results confirm earlier determinations in showing that the international ohm is 5 parts in 10,000 larger than it should be, while the ampere has very nearly the correct value as determined by measurement of mechanical forces between coils. Comparisons of fundamental standards in recent years have shown differences between the standards of different countries large enough to be troublesome in precise scientific work. Direct comparisons between silver voltameters of the Bureau of Standards, the British National Physical Laboratory and the German Physikalisch-Technische Reichsanstalt were made during the year at Berlin; these proved that existing discrepancies arose in large part from changes in the German standard cells. Several years ago the International Committee on Weights and Measures decided that eventually the electrical units should be based upon absolute (mechanical) measurements rather than upon standards arbitrarily defined. The International Committee meets in 1933, and it is hoped that definite plans can then be approved for introducing electrical units on the new basis, assuring international uniformity of values, and removing the discrepancy between electrical and mechanical units.

# Electrical Machinery

## ANNUAL REPORT OF THE COMMITTEE ON ELECTRICAL MACHINERY*

### Activities of the Committee

THE committee during the year has reviewed approximately 50 papers, of which 24 have actually been accepted and published. Work on the preparation of test codes has been carried on during the year, and the Transformer Test Code was published in preliminary form in October. Favorable comments have been received on this, and work on the test codes for induction machines, synchronous machines, and d-c. machines is now approaching completion.

While direct responsibility of the machinery committee for standards, except for transformers, has now been transferred to the Sectional Committee of the A.S.A., the machinery committee has participated indirectly in the revision of the rotating machinery standards, and in particular has sponsored proposals to determine accurate efficiencies of induction and direct-current motors. Mr. C. J. Koch's paper on *Measurement of Stray Load Loss in Polyphase Induction Motors*, presented at the Providence Meeting of the Institute in May 1932, is an important contribution in this field.

The transformer subcommittee has been very active in revising the Transformer Standards No. 13, and it is now undertaking the very important task of standardizing impulse voltage tests.

Revisions in the standards for constant-current transformers and in the Standards Report on Capacitors have also been prepared.

### Synchronous Machines

One of the 200,000-kva., 0.8-power factor, 1800-r.p.m. steam turbine-driven alternators (GE)[1] in the Brooklyn Edison Company's plant has been operated successfully at its rated kilowatt output, and the second unit is being installed. A 121,000-kva., 18,000-volt, 1,800-r.p.m. (AC) unit was placed in operation at Waukegan, and a 147,000-kva., 22,000-volt unit (AC) for the State Line Station is under construction. A 25,000-kva., 13,800-volt, 3,600-r.p.m. machine (W) was shipped to the Public Service Electric and Gas Company and is the largest unit yet undertaken at this speed. A 99,000-kva., 13,800-volt, 1,800-r.p.m. generator (W) is under construction for this company and is the largest unit so far built with internal fans.

Five vertical-shaft waterwheel-driven alternators rated at 48,500 kva., 13,800 volts, 25 cycles, 750 r.p.m. (CGE) are under construction for the Abitibi Cangon Development near James Bay.

A 1,250-kva., 960-cycle, single-phase generator (GE); a 1,250-kva., 1,000-cycle, single-phase generator (GE); and a 3,000-kva., 420-cycle, single-phase generator (GE) represent increases in capacity over high-frequency machines of this type built before the year 1931.

A 75,000-kva., 12,600-volt, 514-r.p.m., synchronous condenser (W) is under construction for the Commonwealth Edison Company. This is an increase of fifty per cent over the previous largest synchronous condenser.

During the year there has been considerable activity in the development of designs to improve the starting performance of industrial synchronous motors, particularly as to higher torque per kva. inrush. Several motors of 200 to 600 hp. at 300 to 900 r.p.m. have been built with a starting torque efficiency (per cent starting torque over per cent kva. inrush or unity power factor base) of the order of 55 per cent.

[1] **Manufacturer Designation:**
**AC—Allis-Chalmers Manufacturing Company**
**BB—American Brown Boveri Company**
**CGE—Canadian General Electric Company**
**CW—Canadian Westinghouse Co., Ltd.**
**ED—Electric Dynamic Company**
**EM—Electric Machinery Manufacturing Company**
**GE—General Electric Company**
**W—Westinghouse Electric & Manufacturing Company**

Two motors for pulp grinder drive (EM) will use stator windings in four parallels, and these motors will be started by applying successively the parallel circuits all on the reduced voltage of the autotransformer. These suitably timed increments will reduce the kva. inrush to a minimum.

The twelve 5,500-hp. motors (GE) for the U. S. Mail S.S. Company have been completed, and two ships with two motors each are in service.

The S.S. *President Hoover* (GE) and the S.S. *President Coolidge* (W) each with two 13,250-hp. motors were placed in service during the year.

Two 30,000-kilowatt frequency changers (GE) with generators rated 42,860 kva., 0.70 power factor, single-phase, 25 cycles, and motors rated 36,000 kva., 0.9 power factor, three-phase, 60 cycles, and operating at 300 r.p.m. are being installed at the Richmond Station of the Philadelphia Electric to supply power to the Pennsylvania Railroad electrification. These sets have twice the capacity of single-phase sets previously built. The generators are equivalent mechanically to 61,000-kva., three-phase machines. The frequency changers are designed for outdoor operation in steel enclosing housings.

## INDUCTION MACHINES

There has been considerable activity during the last year in induction machines. The demand for squirrel-cage motors for rapid and oft-repeated reversing duty, of a nature heretofore confined to d-c. mill type motors, has led to the development of special motors with low inertia rotors and liberal radiating surfaces. This demand came chiefly from the steel mill industry and concerned motors for use on furnace conveyers of the "stroke" type and motors for newly developed automatic sheet handling apparatus as used for hot finishing mills. The simple squirrel-cage motor, while it has some disadvantages as regards disposition of loss, nevertheless offers many advantages for this type of service, *e. g.*, a low-inertia, sturdy, dependable, simple, rotating element, simplified control; faster-operating control; lower-cost motor and lower-cost control. The opening up of this field to squirrel-cage motors will undoubtedly add to the wider application of this type of motor.

The use of totally enclosed fan-cooled motors has increased enormously. One company reports that over half of its induction motor production for last year was of the fan-cooled type. This type of motor is available in mounting dimensions the same as those for open motors of equal rating up to fairly large sizes, and has been well received by the trade where open type motors were subject to aggravated dirt conditions.

Selsyn motors as mediums of control formed a successful means of maintaining levels on both ends of a lift bridge on the Missouri, Kansas, Texas Ry. Other novel applications of this type of motor as a control or as an indicator are under way.

Induction frequency converters of the commutator type have, during the year, been built for use at frequencies as low as $2^1/_2$ cycles. Machines of this type with outputs at ten cycles have been supplied by a large manufacturer to increase the range of his slip-ring frequency converters. These latter, driven by a d-c. adjustable-speed motor, have a normal range of 120 to 180 cycles. By supplying 10 cycles to these converters at approximately $^1/_6$ normal voltage, the frequency range of these converters became 70 to 130 cycles, and a range of 70 to 180 cycles was made possible. These latter frequencies were used to supply small high-speed squirrel-cage motors and give them adjustable-speed characteristics for improvement in manufactured product.

## DIRECT-CURRENT MACHINES

A triple unit motor has been built (ED) for ship propulsion. One auxiliary and two main motors are placed in line with their armatures on one shaft. The auxiliary motor is designed for low cruising speed with higher efficiency than could be obtained in the main motors at low speed.

Two 2,500-hp., 282/708-r.p.m., constant-torque, induction motors have been built (AC) for driving reciprocating, 1,500-lb. per sq. in., boiler feed pumps. The Rossman system of varying speed is used. This is the first case where the d-c. armature has been mounted directly on the rotatable induction motor primary.

A 12,500-hp., 44-inch, slabbing mill drive (W) has been placed in operation. Each main roll is separately driven, without pinions, by a 5,000-hp. double-unit motor; the edging rolls by a 2,500-hp. single motor. Power is supplied by a 10,500-kw., 700-volt, d-c. set composed of one induction motor, 180,000-lb. flywheel, and three 3,500-kw. generators.

A roll grinder has been equipped (W) with nine d-c. motors for controlling separately every motion and adjustment.

## TRANSFORMERS

Manufacturers have given increased attention to the design of both power and distribution transformers to better withstand lightning surges and to developing methods of impulse testing to indicate weakness in transformer insulation to such surges.

Several large shell-type surge-proof power transformers (W) of the new type were built, among them units of 42,000 kva., 220 kv. which were subjected to unusually severe impulse tests, 4,500-kva. units for the Pennsylvania Railroad and a 70,000-kva. unit for the United Electric Light and Power Company, which is thought to be the largest of the self-cooled type in this country.

Self-contained features for protection against lightning independently of transformer connections or grounding practise, and for prevention of outages, were accomplished by incorporating high-voltage deion gaps and coordinated low-voltage bushings in standard distribution transformers (W).

Cover-roof type bushings are a feature of a new line of distribution transformers (AC) intended particularly for service on rural lines.

Two transformers (GE) of new design were fur-

| Total number units in service, Dec. 31st | 180 | 305,379 | 123 | 177,534 |

* Spare rectifier tanks without transformers not included.

nished to operate an X-ray tube for cancer research in the California Institute of Technology. Each unit is rated 0.03 ampere at 700,000 volts to ground continuously, and operates in series with mid-point grounded, giving 1,400,000 volts effective at the X-ray tube.

Magnetic oil level indicators were made available (GE and AC) for power, large distribution, and high-voltage instrument transformers. This gage has numerous advantages over a glass oil gage because it is more easily read, and more easily maintained oil tight. It has no glass to become dirty on the inside or break and allow oil to run out.

The number and capacity of load-ratio control transformers exceeded all previous records. The development of a design (GE) suitable for lower-rated circuits up to 15,000 volts, single-phase or three-phase, resulted in an economical application of load-ratio control to distribution transformer sizes. This type of equipment was applied to the new three-phase 1,500-kva. transformers for high-voltage networks. A new line of standard tap changers (W) using standard parts suitable for wide range of capacities as low as 200 kva. were completed.

A new type of inertaire protection for power transformers (W) using nitrogen from a gas cylinder was perfected. A uni-directional breather (AC) for use on power transformers, which induces a natural circulation of air over the oil in the main transformer tank or expansion tank to reduce condensation and carry off condensed moisture was developed.

## MERCURY-ARC RECTIFIERS

The use of rectifiers has continued to expand during the year as indicated by information contained in Table I.

The large number of additional 3,000-kw. 625-volt units ordered by the New York Board of Transportation is the outstanding feature of this year. Twenty-three of these rectifiers were ordered last year and 28 this year, making a total of 51 sets (GE) with a total capacity of 151,000 kw.

The three 6500-kw. 650-volt electrolytic rectifiers listed in this and last year's report were placed in service during the year.

A 3,000-kw. 650-volt sectional rectifier (W), consisting of four 750-kw. separate rectifiers arranged in a compact unit, was developed and placed in service.

The first complete portable mercury-arc rectifier substation, consisting of a 540-kw., 650-volt (W) rectifier with transformer and control, cooling system, car, etc., was placed in service by the Illinois Power & Light Company.

# Protective Devices

## ANNUAL REPORT OF THE COMMITTEE ON PROTECTIVE DEVICES*

THE work of the Committee on Protective Devices during the past year was handled largely through subcommittees as has been the practise for several years. These subcommittees are listed below together with their chairmen:

| | |
|---|---|
| Relays | O. C. Traver |
| Oil Circuit Breakers, Switches, and Fuses | T. G. LeClair[1] |
| Lightning Arresters | H. K. Sels |
| Fault Current Limiting Devices | R. T. Henry |
| Interconnections[2] | F. C. Hanker |

### GENERAL

The committee continued its activities in following the preparation of standards, and review of research and development, although the main activity during the year was fostering the preparation and presentation of papers before the Institute.

While the technical achievement during the year is very satisfactory in view of the general business conditions, these conditions of course had a depressing effect on research and developmental activities. Progress in this respect consisted largely of refinements and extensions of fundamentals previously established.

Difficulty in securing agreement relative to certain matters concerning the standards for fuses and the revised standards for disconnecting, horn-gap and knife switches has prevented completing these standards. Plans have been made for a course of action which it is believed will permit of putting these standards into report form. Every effort is being made to place these standards in such shape that complete agreement may be secured which will permit their adoption as Institute Standards.

### RELAYS

#### *Report of Subcommittee*

The development of high-speed relays continued, resulting in marked improvements to primary power-system relays generally, and in new developments in the a-c. railway and secondary distribution network system fields.

One of the manufacturers has developed so-called straight-line relays, particularly for application on 4,000-volt networks which are capable of discriminating and operating on very small differences in current, although these currents may be quite heavy.

An important advance during the year was the redesign of all types of relays by at least one manufacturer in order to accommodate the relays in a new universal case, with standard stud arrangement, which is being used to a large extent for front of panel switchboard devices.

A high-speed current differential relay for transformer protection having an operating speed of 0.004 second has been developed.

Numerous refinements in mechanical details contributing to the reliability and accuracy of relays of all types have been carried forward.

Completed developments in coupling and protective equipment for all carrier-current applications include cable-type coupling-capacitor assemblies for all voltages from 115 to 230 kv., inclusive.

In order to secure a consensus of present day practise in regard to protection of apparatus of all classes, a questionnaire on this subject has been sent to a number of engineers, and a number of replies has already been received.

An important advance in relay application during the past year has been the wide increase in the use of the method of symmetrical components for determination of not only the fault current but also the voltage and current at the relay location, particularly for distance relay applications.

The following papers appearing under the auspices of the committee have been presented before the Institute:

*A New High-Speed Distance Relay,* S. L. Goldsborough and W. A. Lewis, Westinghouse Electric & Manufacturing Co.

*Application of High-Speed Relays,* G. W. Gerrell, Union Electric Light & Power Co.

*A New High-Speed Distance Relay,* A. R. Van C. Warrington, General Electric Co.

*Relay Operation From Bushing Potential Devices,* P. O. Langguth, Westinghouse Electric & Manufacturing Co., and V. B. Jones.

*Operation of Relays From Carrier-Current Coupling Capacitors and Capacitance Transformer Bushings,* J. E. Clem and R. E. Cordray, General Electric Co.

*Effect of Wave Form on Operation of Induction Relays,* P. H. Robinson, Houston Lighting & Power Co.

*A Telegraphic Pilot-Wire Relay System,* C. H. Frier, Oklahoma Gas & Electric Co.

### OIL CIRCUIT BREAKERS, SWITCHES, AND FUSES

#### *Report of Subcommittee*

Intense interest has been shown during the year in the fundamental theories underlying the various circuit breaker developments of the last few years. These discussions have resulted in clarifying conceptions of the theories on which these new types of breakers operate and has laid ground work for further development in the future. The amount of fundamental development which this intensive scrutiny reveals will, if supported by satisfactory performance records, do much to increase the confidence of the user in the ability of oil circuit breakers to perform adequately.

---

* **COMMITTEE ON PROTECTIVE DEVICES:**

Raymond Bailey, Chairman,
L. F. Hickernell, Vice-chairman,
H. W. Collins,
A. W. Copley,
W. S. Edsall,
L. E. Frost,
S. L. Goldsborough,
R. T. Henry,
E. A. Hester,
T. G. LeClair
J. B. MacNeill,
J. P. McKearin,
H. A. McLaughlin,
D. M. Petty,
H. J. Scholz,
H. K. Sels,
H. P. Sleeper,
L. G. Smith,
E. R. Stauffacher,
H. R. Summerhayes,
O. C. Traver,
E. M. Wood,
H. B. Wood.

[1] Mr. LeClair was appointed chairman of the subcommittee on oil circuit breakers, switches, and fuses on January 4, 1932, when Mr. Hickernell resigned as chairman of this subcommittee.

[2] The interconnections subcommittee is a joint subcommittee having representation from the following committees: Protective Devices, Power Generation, Transmission and Distribution, Electric Machinery.

The metal-clad switchgear has been improved in a number of details and the development has been extended to interrupting ratings of 500,000 kva. at 15 kv. for indoor breakers and to 1,500,000 kva. at 132 kv. for outdoor breakers.

The oil-blast and deion grid principles of breaker construction were extended to quite high ratings, and both types have appeared in the metal-clad construction. Elaborate tests on a 1,500-ampere 15-kv. high-speed deion circuit breaker were performed for a railway application. Seventy-two short circuits ranging from 2,720 amperes to 50,500 amperes were thrown on the breaker in about five hours time. Some of these short circuits lasted only 0.024 second and the duration of the longer ones was 0.04 second. A series of fifty tests at current values from 11,000 to 49,000 amperes was run on impulse type of oil-blast breaker of a corresponding rating. This breaker clears the circuit in 0.04 second or less over the full current range.

Developments in air circuit breakers include extension of current ratings and improvements in operating speed.

The fuse manufacturers have been active in the development of improved type fuses, which are more economical.

There is a fairly widespread feeling among operating engineers in particular that some improvement could be made on the basis of rating of oil circuit breakers.

The following papers appeared under the auspices of the committee and have been presented before the Institute:

*The Theory of Oil-Blast Circuit Breakers*, D. C. Prince, General Electric Co.

*The Practical Application of the Oil-Blast Principle of Circuit Interruption*, R. M. Spurck, General Electric Co.

*Recent Developments in Arc Rupturing Devices*, R. C. Van Sickle and W. M. Leeds, Westinghouse Electric & Manufacturing Co.

*The Extinction of Alternating Current Arcs in Turbulent Gases*, T. E. Browne, Jr., Westinghouse Electric & Manufacturing Co.

*Application of Primary Distribution Fuses*, F. E. Sanford, Union Gas & Electric Company.

*The Expulsion Fuse*, J. Slepian and C. L. Denault, Westinghouse Electric & Manufacturing Co.

*Fuse Cut-Outs—Their Design and Application for A-C. Distribution Circuits*, E. G. Newton, General Electric Co.

*The Boric Acid Fuse*, A. P. Strom and H. L. Rawlins, Westinghouse Electric & Manufacturing Co.

## FAULT CURRENT LIMITING DEVICES

### *Report of Subcommittee*

The committee is not aware of any developments relating to fault current limiting devices of sufficient importance to warrant including in this report. Operating experience with such devices apparently continues to be quite satisfactory, and the need for further development is therefore not particularly urgent.

## LIGHTNING ARRESTERS

### *Report of Subcommittee*

As in other lines, the developments on lightning arresters consist principally of extensions of recently developed, fundamental theories to a greater variety of forms of station and line type arresters; also, a marked improvement has been made in the mechanical design and construction of lightning arresters which will improve the maintenance of their electrical characteristics.

Studies of lightning and the effects of lightning on power systems were continued during the year with considerable improvement in the technic of fault location. Newly developed lightning current meters and special low resistors were used to measure the current in the lightning stroke.

Continued field investigations using portable surge generators and cathode ray oscillographs, were made in conjunction with study of applications of lightning arresters to distribution transformer installations and associated line construction.

Considerable experimental work concerning grounds and ground connections resulted in making available information which may be used to improve the effectiveness of lightning arrester applications.

New protective devices have been developed, arranged for installation inside of the distribution transformer. This development marks a new phase in the problem of protection of transformers against the effects of lightning and should result in very much improved operating experience.

A report is in preparation jointly with the N.E.L.A. Subject Committee on Lightning Arresters, outlining the prevailing practise on the installation, operation, and experience of various types of lightning arresters by a number of the larger operating companies. This information should be valuable in observing the present trend of operating practise on transmission and distribution systems relative to arrester installation, operation, and performance as affecting suitable standards, and also whether tests and equipment should be developed to determine the operating condition of arresters in service.

Lightning arrester manufacturers have contributed largely to the development of more powerful testing equipment and more accurate recording apparatus which has been used to carry out the proposed tests outlined in the Report on Standards for Lightning Arresters and has effectively demonstrated the value of these tests to determine the characteristics of lightning arresters.

The report on Standards for Lightning Arresters continues in its tentative form and it will probably not be feasible to revise this report until work now in progress on the characteristics and coordination of system insulation with respect to lightning has progressed further.

### INTERCONNECTIONS

#### *Report of Joint Subcommittee*

The Joint Subcommittee on Interconnections includes representatives of the Protective Devices, Power Generation, Transmission and Distribution, and the Electric Machinery Committees.

At the Winter Convention 1932 the session under the auspices of the subcommittee included two subjects of particular interest to the Protective Devices Committee, namely, the "Report of the Subject Committee on Definitions of Terms Used in Power System Studies" and the papers presenting revised decrement curves.

The activity of various engineering groups in studies of interconnection has built up a terminology for which there has been no official recognition. A Subject Committee has been at work on these definitions for some time and presented a report that will be used as the basis for the consideration of such definitions by the responsible standardizing bodies. A large number of these definitions is related to subjects of interest to the Protective Devices Committee.

The papers on decrement curves and short circuit calculations are:

*I—Standard Decrement Curves*, W. C. Hahn, General Electric Co. and C. F. Wagner, Westinghouse Electric & Manufacturing Co.

*II—Calculation of Short Circuits on Power Systems*, C. F. Wagner, Westinghouse Electric & Manufacturing Co., and S. H. Wright, Buffalo, Niagara & Eastern Power Corporation.

*III—Decrement Curves for Specific Systems*, W. C. Hahn, General Electric Co.

During 1918, Messrs. Burnham, Hewlitt, and Mahoney discussed decrement curves for relay and circuit breaker applications before the Institute. The group of papers presented at the last Winter Convention brings the subject up to date, utilizing the further knowledge of machine characteristics accumulated in the intervening period.

# Instruments and Measurements

## ANNUAL REPORT OF COMMITTEE ON INSTRUMENTS AND MEASUREMENTS*

THE Committee on Instruments and Measurements during the year 1931–32 has had an active membership of 23 members. At the meeting held in October 15 members were in attendance, and at the meeting held in January 13 members attended. Considering the geographical distribution of the membership, this attendance is exceptionally good.

The work has been organized through subcommittees to take care of the following subjects:

1. Recording instruments
2. Telemetering
3. Definitions of instruments and testing
4. Instrument transformers
5. Indicating instruments
6. Temperature measurements
7. High-frequency measurements

### SUBCOMMITTEE ON RECORDING INSTRUMENTS

This subcommittee has been engaged for several years on the development of standards for recording instruments. During the year its work was completed and a draft of the proposed standards was approved by the Instruments and Measurements Committee. These have been forwarded to the Secretary of the Standards Committee for adoption and publication. This subcommittee has been under the chairmanship of Mr. Kinnard and is to be complimented on the completion of a task which involved such a large amount of painstaking work.

### SUBCOMMITTEE ON TELEMETERING

This subcommittee has concluded its work on standard definitions which have been approved by the Instruments and Measurements Committee. These have been submitted to the Secretary of the Standards Committee.

In addition to its work of following developments in this field, it has undertaken to cooperate with a subcommittee of the Automatic Stations Committee in the preparation of a report on telemetering and supervisory control systems and related communication systems. This report is a very comprehensive survey of all the known telemetering systems, which have been critically analyzed so as to provide detailed information in regard to the limitations and operating characteristics of each. It is hoped to have this report for the Summer Convention. Mr. E. D. Doyle is chairman of this subcommittee.

---

* **COMMITTEE ON INSTRUMENTS AND MEASUREMENTS:**

E. J. Rutan, Chairman,
H. S. Baker,
R. D. Bean,
O. J. Bliss,
P. A. Borden,

E. S. Lee,
J. B. Lunsford,
Paul MacGahan,
R. T. Pierce,
W. J. Shackelton,
H. L. Thomson,
H. M. Turner.

### SUBCOMMITTEE ON DEFINITIONS OF INSTRUMENTS AND TESTING

This subcommittee is an outgrowth of the cooperation of the Instruments and Measurements Committee with the Sectional Committee of the American Standards Association which is preparing definitions on instruments and testing. Mr. E. S. Lee as chairman of this subcommittee has been assisted by the chairmen of the Recording Instruments, Telemetering, Instrument Transformers, and Indicating Instruments subcommittees as well as all of the members of the Instruments and Measurements Committee. Many valuable suggestions and considerable work has been done in the criticism, correction, and re-arrangement of several of the drafts of definitions submitted to this subcommittee. Joint meetings were arranged with the members of the Sectional Committee and, as a result, an acceptable draft of these definitions has been completed.

### SUBCOMMITTEE ON INSTRUMENT TRANSFORMERS

The Subcommittee on Instrument Transformers has been active for the past two years in the revision of standards No. 14 and has about completed its work and is preparing to submit a final draft of these standards to the members of the Instruments and Measurements Committee. Mr. J. B. Gibbs is chairman of this subcommittee.

### SUBCOMMITTEE ON INDICATING INSTRUMENTS

Indicating instruments standards No. 23 which have been available to the industry since 1927 have been under consideration for revision during the past year. Based on considerable progress in the art since the standards were issued and the experience of the Instruments and Measurements Committee, many desirable changes will be made and new data incorporated in these standards. An early report from this subcommittee is expected which, upon approval by the Instruments and Measurements Committee, will be forwarded to the Standards Committee. Mr. H. C. Koenig is chairman of this subcommittee.

### SUBCOMMITTEE ON TEMPERATURE MEASUREMENTS

This subcommittee, which is under the chairmanship of Mr. H. C. Koenig, has been working on the preparation of a standard code for temperature measurements. The scope of this work is to cover all the requirements of temperature measurements as specified in the various standards of the Institute. It is expected, when completed, a very comprehensive procedure will be available for uniform measurements of temperature.

### SUBCOMMITTEE ON HIGH-FREQUENCY MEASUREMENTS

This subcommittee has been active under the chairmanship of Prof. H. M. Turner. Arrangements were made to cooperate with a committee appointed by the Standards Committee to draft definitions and standards for sound measurements. The subcommittee is also making a study of vacuum tube voltmeters and will prepare a report on this subject during the coming year.

### INSTITUTE SESSIONS AND PAPERS

In addition to the Committee work through its subcommittees on definite subjects, arrangements were made for the promotion of a session at the Mid-Winter Convention. Six papers were presented and are listed below:

1. *High Voltage Bridge for Measurements of Cable with Grounded Sheaths*, C. L. Dawes and A. F. Daniel.
2. *A High Sensitivity Power Factor Bridge*, W. B. Kouwenhoven and Alfredo Banos, Jr.
3. *Capacitance and Power Factor Measurement by the Capacitance Bridge*, R. P. Siskind.
4. *An Automatic Oscillograph*, C. M. Hathaway and R. C. Buell.
5. *The Photoelectric Recorder*, C. W. La Pierre.
6. *Aging and Elastic Hysteresis in Instrument Springs*, P. MacGahan and R. W. Carson.

In addition to the papers presented at the session, the following papers were reviewed by the various members of the Instruments and Measurements Committee and commented upon:

1. *The Metering of Symmetrical Components*, G. R. Shuck.
2. *Electrical Measurements of Sound Absorption*, A. L. Albert and W. R. Bullis.
3. *Electrical Solutions of Problems of Regular Scheduled Flight*, C. F. Green.
4. *The Photoelectric Recorder*, C. W. La Pierre.
5. *A Standard of Low Power Factor*, W. B. Kouwenhoven.
6. *Electrical Measurements in the Gas Industry*, E. X. Schmidt.
7. *A Special Application of the Potentiometer Principle*, J. L. Watson and R. C. Gleeson.
8. *A Bridge for Precision Power Factor Measurements on Small Oil Samples*, J. C. Balsbaugh and P. H. Moon.
9. *Skin Effect in Rectangular Conductors*, H. C. Forbes and L. J. Gorman.

### CONCLUSION

The Chairman wishes to acknowledge at the completion of his two years of office the hearty cooperation of all of the members of the Instruments and Measurements Committee. The work of the vice-chairman, secretary, and chairmen of the subcommittees was of especial importance in the successful completion of many of the projects which we had before us. From several years contact with this committee as a member and as chairman, the writer has been very much impressed by the interest displayed, and feels highly confident concerning the continued activity in this field of the electrical engineering art as sponsored by this committee.

# Transportation

## ANNUAL REPORT OF THE COMMITTEE ON TRANSPORTATION*

### Railroad Electrification

THE Reading Company began operation on July 26, 1931, of the first portion of its electrified suburban service running out of Philadelphia. Multiple-unit cars are now operated over 64.6 miles of route embracing 156.9 track miles and the electrification of two more branches is in progress, the completion of which will bring the total electrified mileage to 86.9 route miles or 203 track miles. Single-phase, 25-cycle, alternating current is supplied by the Philadelphia Electric Company through outdoor frequency changer sets located on the railroad's property at Wayne Junction, and is distributed to the trains over a 36,000/12,000 three-wire system with 12,000 volts between the overhead contact wires and the rails, and 24,000 volts between the rails and the feeders carried on the catenary structures. Provision has been made on these structures for supporting transmission lines of higher voltage when future extensions of the electrification make it necessary. Over a part of the right-of-way steel towers are to be used jointly by the power company for high-voltage transmission and by the railroad for supporting its catenary system. All of the power switching is handled from a single supervisory control board at Wayne Junction, at which point also are located the repair shops and storage yards for the car equipment.

The Pennsylvania Railroad Company has made very considerable progress on its project for complete electrification between New York and Washington. The overhead contact system has been installed in the New York Terminal zone between Sunnyside Yards on Long Island and Manhattan Transfer in New Jersey, where d-c. third-rail locomotives have been used hitherto, and a-c. locomotives are now handling some of the trains. Construction is progressing between Manhattan Transfer and Trenton, New Jersey, the completion of which, in association with the work already done, will permit electric operation from New York as far as Wilmington. The erection of catenary structures between Wilmington and Washington has been begun. Several locomotives of the new standard designs have been placed in service. The motors on the two types of passenger locomotives (2-B-2 and 2-C-2) and the road freight locomotive (1-D-1) have interchangeable armatures, stators, and other parts, those on the passenger engines being mounted in twin frames, a pair for each driving axle, while those on the freight locomotive are mounted independently one on each of the four driving axles. The motors all have a continuous rating of 625 hp. per armature. Standardization and interchangeability of parts have been carried out as far as possible throughout the design of these locomotives, both in the mechanical parts and in the electrical equipment. These standard motive power units may be operated in various combinations to provide the tractive effort required for different classes and weights of trains.

The New York Central Railroad has eliminated the use of steam locomotives on its "West Side" line in New York City, full operation by either electric or oil-electric locomotives having been inaugurated in June 1931. Third rails supplying direct current at 650 volts have been installed as far south as 72nd Street, but only to a very small extent in the yards between 72nd and 60th Streets. No external power supply has as yet been provided on the tracks which lead (still largely on the city streets) to the smaller yards and terminals further downtown. The locomotives which handle the switching and transfer work in this territory have oil engine-generator sets and storage batteries to provide their own power, but are also equipped to receive power from the third rail where it is available.

The New York, New Haven & Hartford Railroad has placed in operation the ten new passenger locomotives mentioned in last year's report. They weigh 403,000 lb. and have the axle arrangement 2−C+C−2 with a weight on drivers of 45,600 lb. per axle. Each of the six driving axles is connected by quill and gear to a twin motor with a continuous rating of 550 hp. These locomotives are notable for improved motor design, giving better commutation and increased tractive effort.

Oil-electric locomotives, as well as oil-electric and gasoline-electric rail motor cars, are finding an increasing number of applications. Seven such locomotives recently placed in service by the Bush Terminal Company in Brooklyn, New York, are unique in that their cabs, underframes, and trucks were fabricated entirely from structural shapes and plates, with electric welding and no riveting.

Air conditioning on passenger cars and experiments with rubber-tired rail cars are among recent developments in railroading which contain elements of interest to the electrical engineer.

### Railroad Signaling

A number of additional installations of the recently developed methods of centralized traffic control was made during the past year. These, together with the completion of many new interlocking plants, automatic signals, highway crossing signals, and car retarders kept the record of progress in the installation of signaling facilities up to about 65 per cent of that in the previous year in spite of the reduction in the volume of construction in general.

## URBAN TRANSPORTATION

The New York City Board of Transportation has practically completed the equipment of the new Eighth Avenue Subway from Fulton Street to 207th Street, Manhattan, and has received 300 cars which have been tested in trial runs and are ready for the beginning of operation. Five hundred more cars have been ordered in preparation for extension of the service to other sections of the new system which are under construction in the boroughs of Brooklyn, Queens, and the Bronx. The substation equipment for these lines will include 16 converters in five substations with an aggregate capacity of 53,000 kw., and 62 mercury arc rectifiers rated at 3,000 kilowatts each, most of which will be placed in individual subterranean compartments along the subway lines.

Systematic efforts are being continued to design a type of street car which will more successfully meet the competition of the buses and the private automobiles. The tendencies are toward the use of light-weight, double-truck cars, with small wheels and low floors, equipped with small high-speed motors giving rapid acceleration and high car speeds. Control has been improved by the use of a larger number of resistance steps and also by the introduction of "variable-automatic control" in which the operation of the resistance contactors is governed by relays, but the motorman can select the rate of acceleration according to traffic or rail conditions. Braking by means of electromagnetized shoes on the car acting against the running rails is being used to some extent. Higher speed and lighter weight are the tendencies in interurban cars also, and some attention is being given to improvement in body design to reduce wind resistance.

The use of trolley buses is being extended, such vehicles having been purchased for seven cities during 1931, at the end of which year there were 225 trolley buses in operation in 14 cities in the United States.

## MARINE TRANSPORTATION

The two largest passenger liners built in the United States, the *President Hoover* and the *President Coolidge*, were placed in operation during the past year in intercoastal and transpacific services. Each of these twin ships has two 10,000-kw. turbine-driven generators which supply the synchronous-induction propulsion motors with three-phase, alternating current at 4800 volts, and also four 500-kw. turbine-driven d-c. generators which very completely serve the auxiliary equipment on board, including steering gear, winches, capstans, air compressors, refrigerating machines, blowers, pumps of all sorts, elevators, cooking equipment, stateroom heaters, fans, etc., in addition, of course, to searchlights and general lighting. Several other smaller motor-propelled vessels with generators driven by steam turbines or oil or gasoline engines were placed in commission during the year. (See also the report of the Committee on Applications to Marine Work.)

## AERIAL TRANSPORTATION

The U.S. Navy dirigible *Akron* carries considerable electrical equipment, including a searchlight and general lighting, cooking appliances, radio equipment, a battery charging set and other motors. The energy is supplied by two 11-kw., 115-volt d-c. generators driven by gasoline engines. The huge mooring mast, by which the dirigible is towed into and out of its hangar at Lakehurst, N. J., is propelled by two caterpillar tractors driven by 125-hp., 250-volt, d-c. motors and is steered by a third caterpillar driven by an 8-hp. motor. A 240-hp. gasoline-driven generator supplies these motors as well as floodlights and signaling apparatus on the mast and equipment for conveying water, fuel, and electricity to the dirigible.

A novel type of electric locomotive is used to tow models of sea-plane hulls or pontoons in a testing channel 2,000 ft. long, 22 ft. wide, and 12 ft. deep, recently completed at Langley Field, Va. The towing car spans the tank and is driven by four 75-hp. motors. The remarkable feature is its rapid acceleration, as it is said to reach a speed of 60 miles an hour in 9 seconds.

Important improvements were made during the year in radio equipment for communication between airplanes and the ground and for direction finding. These include automatic volume control, which relieves the pilot of the necessity of making manual adjustment of receiver amplification over a wide range of distances, and also practicable means of giving visual indication in connection with the direction finders.

Among electrical devices perfected for application to aviation may be mentioned an instrument for indicating engine cylinder temperature which is so calibrated and compensated as to show directly in degrees the temperature of various parts of the engine where thermocouples are installed. The leads from several thermocouples are brought to the indicator through a selector switch. Another device is the sonic altimeter in which a compressed air whistle produces signals electrically timed and controlled, which are reflected from the ground. The echo is heard in a stethoscope and, by means of a timing indicator mounted on the instrument panel, the time interval between outgoing and returning signals is interpreted directly in terms of distance above the ground.

## VERTICAL TRANSPORTATION

The opening of the Empire State Building in New York City in 1931 placed in service the largest installation of elevators yet made. These are all of the automatic type and those serving the upper part of the tower have higher speeds and longer vertical travel than any previously installed. Improvements in construction and in the control of emergency stopping devices now permit speeds up to 1200 ft. per minute.

An installation of double-deck elevators, serving two floors simultaneously, has been made in the tower of the new Cities Service Building in New York City. In this same structure there is also the first installation of escalators in an office building, a means of transportation which is being used more and more extensively in department stores, railway stations, etc.

The arrangement, mentioned in last year's report, in which two independent elevators are operated in the same shaft, one running express to the upper floors and the other serving the lower floors, with suitable safety interlocking, appears to be a thoroughly practical development. Such elevators are in service in one of the Westinghouse buildings in East Pittsburgh.

# Applications to Marine Work

## ANNUAL REPORT OF COMMITTEE ON APPLICATIONS TO MARINE WORK*

As in the past few years, the major items of activity of the committee have been:

1. Accumulating, as a result of experience, data for revision of Standards No. 45, Recommended Practise for Electrical Installations on Shipboard.
2. Promoting the idea of establishing a definite status of the electrical operating personnel on shipboard.
3. Following closely installations of electric propulsion and electrification of auxiliaries on shipboard.

### STANDARDS NO. 45

These standards are proving to be more and more useful to naval architects, shipbuilders, ship operators, and manufacturers of electrically driven auxiliaries. As a result of this increase in use, it is natural that changes and additions should be found desirable. During the past year the committee has continued to collect data for such revisions and when the volume of this data seems to justify a reissue of the standards, the committee expects to recommend such action to the Institute.

### OPERATING PERSONNEL

For some years the committee has felt it important that the personnel in charge of the electrical machinery on ships should have a more definite status than is now in vogue. With the increasing use of electricity for both propulsion and auxiliaries, the necessity for such a recognized status has become more urgent. Our first efforts were based upon improving the status of electrical operating personnel through governmental channels, but as a result of experience, it has become apparent that our efforts will probably meet with more success if we cooperate with the owners and operators of vessels to this end; hence, during the past year we have been in further conferences with the American Steamship Owners Association and we believe that we are about to arrive at such a working agreement with this association as will lead to definite results.

### ELECTRIC PROPULSION AND AUXILIARIES

As stated in last year's report, the year 1930 was one of great activity, progress and accomplishment in marine engineering, generally. This was due largely to the passage of the Jones-White Merchant Marine Act in 1928. This activity resulted in contracts being let for a large number of ships with electric propulsion and auxiliaries.

Due to the present financial depression the past year has not been marked by such activity, but the program started the year before has continued to be executed without cancelation of contracts.

The following table shows the status during the year of new ships in the U.S.A. equipped with electric propulsion:

SHIPS COMMISSIONED IN THE U.S.A. DURING 1931

*Turbine Electric Drive*

| Name | Type | Horsepower |
|---|---|---|
| *PRESIDENT HOOVER* | Passenger Cargo | 26,500 |
| *PRESIDENT COOLIDGE* | Passenger Cargo | 26,500 |
| *TALAMANCA* | Passenger Cargo | 10,500 |
| *CAYUGA* | Coast Guard Cutter | 3,220 |
| *SHOSHONE* | Coast Guard Cutter | 3,220 |
| | Total | 69,940 |

*Diesel Electric Drive*

| Name | Type | Horsepower |
|---|---|---|
| *COLUMBINE* | Lighthouse Tender | 240 |
| *LINDEN* | Lighthouse Tender | 240 |
| *GULF MIST* | Tanker | 400 |
| *WHITE FLASH* | Tanker | 375 |
| *SAN DIEGO* | Ferry | 750 |
| *DUPLEX* | Dredge | 600 |
| | Total | 2,605 |

SHIPS UNDER CONSTRUCTION IN THE U.S.A. DURING 1931

*Turbine Electric Drive*

| Name | Type | Horsepower |
|---|---|---|
| *SEGOVIA** | Passenger Cargo | 10,500 |
| *CHIRIQUI* | Passenger Cargo | 10,500 |
| *ANTIGUA* | Passenger Cargo | 10,500 |
| *QUIRIGUA* | Passenger Cargo | 10,500 |
| *VERAGUA* | Passenger Cargo | 10,500 |
| | Total | 52,500 |

* Destroyed by fire Dec. 1931.

# Production and Application of Light

## ANNUAL REPORT OF THE COMMITTEE ON PRODUCTION AND APPLICATION OF LIGHT*

## PRODUCTION OF LIGHT

### *Statistics on Lighting Progress as Indicated by Incandescent Lamp Sales*

THE production and use of artificial light, as indicated by the sale of incandescent lamps, decreased slightly during 1931 as compared with previous years. In actual numbers of lamps sold the decrease was not great. The average wattage decreased from 61.2 to 60.9 watts, lamp efficiency from 13.3 to 13.4 lumens per watt and average lumens from 814 to 817.

The continued increase in the use of 120 volts for lighting circuits is notable. The percentage of 120-volt lamps sold increased from 41.3 per cent in 1930 to 43.9 per cent in 1931, while 110- and 115-volt lamps decreased from 5.2 per cent to 3.7 per cent and 48.9 per cent to 48.0 per cent, respectively. The adoption of the three-phase four-wire network system of distribution is probably the major factor influencing this trend.

Street lighting continues to show an increase both in the number of lamps used and in the average light output.

## NEW INCANDESCENT LAMPS

### *Photoflood Lamps*

A companion lamp for the photoflash lamp has been developed—the photoflood lamp. The photoflash lamp is intended for use in making snapshots, while the photoflood lamp is intended for time-exposures and for home or amateur motion picture photography. The new lamp has a bulb of the same size and shape as the standard 60-watt lamp but is rated at 250 watts and operates at an extremely high efficiency. In light output it is equivalent to a standard 500-watt lamp but in photographic effect, due to a high percentage of actinic light, it compares with a 750-watt lamp.

### *Neon-Filled Christmas Tree Lamps*

Christmas trees are illuminated usually by strings of eight 15-volt lamps burning in series. The failure of one extinguishes the entire string and it is necessary to try each successive lamp in the string until the burned-out lamp is located. Neon-filled lamps have been developed which operate in the usual manner until one fails. This impresses the full line voltage across that particular lamp and causes it to glow with the characteristic neon red. As the current producing the glow is not sufficient to light the remaining lamps, the burned-out lamp is identified readily.

### *Inside Frosting 150 to 500-Watt Lamps*

The inside frosted finish has been made available for lamps of 150 to 500 watts. This finish is desirable for lamps used in light density enclosing globes and in indirect lighting units since it diffuses the light and eliminates sharp shadows.

### *Addition of 1,500-Watt Lamps*

Increasing use of high intensity illumination produced a demand for 1,500-watt lamps sufficient to warrant their inclusion in the regular lamp schedules.

### *Elimination of 600- and 800-Lumen Lamps*

Authorities on street lighting practise consider the use of lamps of less than 1,000 lumens output inadvisable. The 600- and 800-lumen, 6.6-ampere lamps have been removed, therefore, from the regular schedules.

## IMPORTED INCANDESCENT LAMPS

Electric lighting in America has enjoyed a favorable lamp situation in that a great majority of the lamps supplied to the public have been of well-controlled quality and of highest practicable efficiency. This condition is threatened now with impairment due to the advent of inferior lamps. Notable among these are lamps imported from Japan and sold through irregular channels of distribution. The Committee is informed that aside from miniature lamps, about twenty millions of Japanese lamps were imported during the last year. These were characteristically of such low efficiency that at prevailing rates for current the public could not afford to use them.* Defects which interfere with satisfactory service were unduly prevalent among them and their life performance was very irregular and inconsistent.

---

* COMMITTEE ON PRODUCTION AND APPLICATION OF LIGHT:
W. T. Blackwell, Chairman,
J. W. Barker,
H. S. Broadbent,
J. M. Bryant,
W. T. Dempsey,
E. E. Dorting,
L. A. Hawkins,
H. H. Higbie,
C. L. Kinsloe,
R. D. Mailey,
G. S. Merrill,
P. S. Millar,
P. H. Moon,
R. E. Simpson,
C. J. Stahl,
G. H. Stickney.

In drawing attention to this development, the Committee bespeaks coöperation of electrical engineers generally in doing all that may be practicable to prevent the impairment of American lighting by lamps of inferior quality.

### BASE AND SOCKET STANDARDIZATION

At the present time the screw bases and sockets standard in Europe differ slightly from the original American Edison standard in such a way that American lamps are not assured of fitting in European sockets, but European lamps can be put in American sockets, though failing to meet American safety requirements. Although many more American sockets and bases are in actual use, it was proposed to adopt the European design as the international standard. At a meeting of the International Electrotechnical Commission's Committee, held concurrently with the 1931 sessions of the International Commission on Illumination, the American standards were recommended on a par with the European and plans were advanced looking toward a single universal standard of intermediate dimensions.

### PROPER OPERATING VOLTAGE

The voltage at which incandescent lamps are operated affects their input, output, efficiency, rate of depreciation, and cost of producing light to such an extent that it cannot be overlooked in any consideration of the production and application of light involving such sources.

The N.E.L.A. Lamp Committee Report for 1930–31* contains a study of operating voltages in use in some 24,590 communities. The detailed figures presented in the report reveal an undesirable tendency toward the increased use of more than one standard voltage in individual communities. Such dual standards make it difficult, if not impossible, to insure that lamps of proper voltage are used. During the five-year period from 1923 to 1928 there was a marked reduction (13.2 per cent to 5.4 per cent) in the extent to which two lighting service voltages were used by any one community, but in the last years this has increased again.

### WIRING SPECIFICATION

Of the specifications mentioned in last year's report, the "Minimum Specification for Wiring of Lighting Circuits in Industrial Structures" was issued during the summer.

Regarding residence wiring, several associations undertook independently the development of specifications. An industry committee was organized to coördinate the work and prepare amplified specifications acceptable to all groups. This work is reported now to be complete, subject to final approval by the several associations. It is understood that the proposed specification sets No. 12 wire as the smallest size to be recommended for any lighting circuit. This limitation, corresponding as it does to that of the commercial and industrial specifications, should help eliminate smaller sized wire from good standing with the designers of electric light wiring, and thus advance good engineering in this field.

### CARBON ARCS

Recent careful control tests of various sources of illumination with respect to their speed and color reproduction in photography have shown that the white flame photographic carbon almost exactly duplicates the results obtained with natural sunlight

N. B. Burning the Types S-1 and S-2 lamps at an angle of 45 degrees reduces their ultra-violet outputs 30 and 40%, respectively. Eliminating the wire screen on the Type S-1 units increases their output about 20%.

* Also available for 28–32 volt circuits.

** Since the entire bulb glows this dimension is base contact point to center of bulb which is also the center of the electrodes.

† Estimated.

and gives a nearly perfect separation of color values in effective shades of gray.

In the field of motion picture projection, carbons have been developed which are steadier in burning and, in certain sizes, even higher in intrinsic brilliancy than those formerly obtained.

Precratering of high intensity positives has resulted in a more rapid burning in of natural craters and full intensity of illumination, as well as a resultant saving in costs by reducing the possibility of mirror or condenser pitting.

For searchlights used in airport floodlighting and military purposes, carbons have been developed which will give from 50 to 100 per cent more light at 225 and 250 amperes than has been possible previously with regular searchlight carbons.

## ULTRA-VIOLET—INCANDESCENT TYPE

Last year's report mentioned the introduction of four new sources of ultra-violet radiation emitting little or no wavelength shorter than 2,800 and, therefore, safe for use in the home, the school, office, et cetera; *i. e.*, the Types S-1 and S-2 lamps, the Type G-1 or glow lamp and the CX lamps.

Considerable improvement has been made in these sources since their introduction. The essential technical data pertaining to them are given in Table I.

During the year very complete lines of fixtures have been placed on the market for the Types S-1 and S-2 lamps. Suspension and ceiling type units have been developed which have a spread of both the ultra-violet radiation and the visible light flux. Such units are finding wide application in places where the exposure periods are somewhat limited, such as in swimming pools, gymnasiums, hospital solariums, lunch and recreation rooms, et cetera.

For use in offices, schools, et cetera, where it is desired to combine the health maintenance value of ultra-violet radiation with the lighting over exposure periods of 6 to 10 hours, a third line of equipment, known as dual-purpose lighting fixtures, has been developed. Most of these utilize regular incandescent lamps for indrect or semi-indirect lighting and also an ultra-violet lamp and reflector so designed as to spread a mild intensity of ultra-violet over a wide area.

## GASEOUS TUBE ELECTRIC ILLUMINANTS

It has long been felt that possibilities of materially higher efficiency of light production lie in the domain of electrical discharge through gases rather than in incandescence. While incandescent lamps, with which most artificial lighting is accomplished, are serving the purpose exceedingly well, despite limitations of theoretical low efficiency of light production, and are undergoing gradual evolution which appears to bring them closer and closer to the limits of the possibilities of production of light by incandescence, the engineering world is favorably predisposed toward the idea of achieving efficiencies of a higher order from gaseous tube illuminants.

The present low-voltage gaseous and mercury-vapor arc tubes make available to the illuminating engineer additional lighting tools having characteristics that possess value for particular purposes. Thus the mercury arc lamp, with its characteristic green-blue light, provides a "work light" which has peculiar value for certain industrial applications. The arc tubes of neon or other gases, with their characteristic instantaneous response to electrical discharge, are especially useful in television, stroboscopic work, et cetera. Further, the vivid colors of these tube illuminants make them applicable for certain special uses, such as aircraft beacons, and for publicity purposes. These sources, however, are of the same order of efficiency as tungsten filament lamps.

Beyond these developments the committee has information only of experimental developments in low voltage gaseous arc tube sources. Among these the highest efficiencies of light production attained are in tubes of high power. Pirani's oft-cited sodium tube of special sodium-resistant glass, heated independently to 350 deg. cent. and enclosed within an outer evacuated tube, is said to attain 70 lumens per watt applied to the tube itself. It produces light of a brilliant yellow color. No data are available as to the power required for the complete equipment. Neon and mercury-vapor low-voltage arc tubes, three or more feet in length and consuming 1,000 to 2,000 watts, are said to attain to 35 to 50 lumens per watt. In smaller sizes of lower power input very much lower efficiencies of light production are attained.

In the opinion of the committee attempts to develop gaseous arc tube light sources of a materially higher efficiency than modern incandescent lamps are interesting and perhaps promising. Of practical achievement in the way of commercially applicable illuminants the committee has nothing new to report at this time.

## APPLICATION OF LIGHT

### *New and Improved Incandescent Lamp Equipment*

The standard dome reflector and the glassteel diffuser remain as standard lighting equipment for industrial areas. Recent developments have improved the methods of hanging these reflectors so as to reduce the time required and the cost of cleaning and relamping. The high intensities of light required on certain working areas can be secured by the use of recently developed industrial projectors which can be mounted on the ceiling, side walls or columns and adjusted to project the light in any desired direction.

A totally enclosed semi-indirect lighting unit has been developed with the bottom of the bowl of high density glass and the top portion practically clear. This type of glass makes a highly efficient unit and one easily maintained.

Appearance of the lighting equipment is playing a very important part in commercial installations. The contours of enclosing globe units are more pleasing in design and hangers are receiving considerable attention from the design standpoint. An interesting development in the indirect type of unit is one constructed entirely of metal louvers which can be obtained in a variety of color finishes.

Outdoor lighting such as the floodlighting of buildings and areas devoted to outdoor sports is increasing in popularity. This is partly due to the development of more efficient floodlight projectors and the introduction of open type floodlights. Many manufacturers have discarded the plain parabolic mirror for compound curves forming 2 and 3 surface mirrors. This increases the efficiency and permits accurate control of the beam.

The floodlighting of homes for holiday decorations, and gardens during the summertime, is now made possible by the development of small floodlight projectors designed for use with 100- and 150- watt lamps.

### *Street Lighting*

Street lighting has been referred to frequently, by engineers, as the application of electric light where the practise has lagged most behind growing needs. During the year the demand for smaller municipal expenditures has been reflected in numerous proposals for reduced street lighting. Considerable apprehension was felt by experts lest serious increases in traffic and crime hazards should be incurred for only negligible savings. So far no extensive reduction has been made and several cities, where reduced lighting was tried, returned promptly to former illumination. On the other hand there has been a definite arrest in the advance of street lighting.

### *Group Replacement of Lamps*

Since incandescent lamps operate with almost no attention and a substantial proportion of them last beyond their economic efficiency, many installations fall below their proper illumination performance. The obvious cure is systematic cleaning and replacement at suitable intervals. A recent awakening to the importance of such practises is showing good results. Already about thirty utility companies are applying "group replacement" to their street lighting. Noticeable improvement in illumination and reduced outages are being secured at little, if any, increased expense. Similar methods are applicable to traffic signals, large buildings, large signs, and wherever lamps are grouped in sufficient numbers to permit economic organization of maintenance.

In connection with group replacement, it is desirable to segregate used lamps which have considerable life expectancy from those which are approaching failure. This is facilitated for clear bulb lamps by a new inspection box, which reveals filament defects.

### *Railway Signals in Locomotive Cabs*

Many serious accidents on railroads have resulted from failure of the engine crew to see signals. A new system, being applied extensively by a leading railroad, has a light signal in a conspicuous position in the locomotive cab, where it is independent of weather conditions and its view not limited to a fleeting glance. A sound device calls special attention to changes. The enhancement of safety is obvious.

### *Sports Lighting*

The increasing popularity of artificial illumination in this field is due to the use of more adequate levels of lighting. For example, in football fields about 15 foot-candles have been found to be desirable in contrast to the 5 to 7 foot-candles often recommended in the past. For baseball fields a consumption of about 300 kw. is considered necessary now, whereas 200 kw. was about the maximum of former attempts.

### *Lighting of Buildings Exteriors*

The application of artificial light to the exterior of buildings is making rapid progress, especially in the endeavor to create artistic night-time effects. Lighting effects formerly obtaining only by floodlighting are, in some of the newer buildings, being improved upon by novel methods. Today architects are designing buildings with the idea of artistically lighting the exteriors at night. They are paying attention to the direction of light projection and so designing as to create night-time as well as day-time effects on their buildings. One development is the use of luminous panels built into the façade of the building. Pilasters of diffusing glass behind which are mounted various colored lamps connected to dimmers produce changing color effects. Entire façades are covered with panels of this sort or constructed of glass brick which can be illuminated from behind at night. The development is following gradually that of built-in lighting for interior use.

### *Built-In Lighting*

It is illogical to wait until a building is completed before considering lighting equipment, yet in the past this was generally the case. Now, fortunately, in most new structures the artificial lighting is designed as a component part of the interior. Manufacturers of diffusing material, such as glass, molded plaques and translucent substances, have made available many new varieties and these are finding application. Conventional fixtures designed on traditional lines are passing rapidly from the picture.

### *Residential Lighting*

While the number of newly electrified homes in 1931 decreased to one-seventh the number added in 1930 and to one-seventeenth the number added in 1929, the consumption of electrical energy in homes showed an increase of approximately 8 per cent in 1931, only three or four points less than the increase in previous years when new residential building was at high levels. Decreasing hours spent in the various places of entertainment outside of the home have meant increasing evening hours at home for all members of the family, calling for a greater use of electric light.

The portable lamp has grown in popularity as is evidenced by the increasing number of styles and designs which have been produced. The indirect portable lamp using a 200- or 300-watt lamp has not usurped this field although it has continued to grow in numbers. Decorative floor and table lamps using the Type S-2 lamp have made their initial appearance.

Lighting fixtures providing indirect or semi-indirect lighting and selling at very low prices have been received favorably in various parts of the country for the relighting of certain rooms of the homes of "minimum bill" customers. The design of these fixtures is such that they may be fastened directly to existing single sockets.

The President's Conference on Home Building and Home Ownership devoted a section of its Fundamental Equipment Report to the Wiring and Lighting of the Home, giving attention to these home modernizers equal to that devoted to such items as heating, ventilating, and plumbing.

### *Automobile Lighting*

By means of a three-filament headlamp, a lighting system has been developed giving an asymmetrical distribution of light with reference to the car axis in which more light is directed to the right side of the road, particularly when passing another car. This system is so arranged that a city-driving and a country-driving range of light control is provided.

The advantages of directing more light to the right when passing are well recognized and several auxiliary lighting units are available which when used in connection with the present standard dual beam system provide this desirable passing light.

On some cars the fender lights serve a dual purpose, the switch control being so arranged that in addition to acting as marker lights when the car is parked these fender lamps are lighted when the beam is depressed, thus showing the oncoming driver that the depressed beam is being used and giving in addition an indication of the extreme width of the car.

Two rear lamps are being supplied for many current model motor cars. These lamps are generally a combination rear and signal unit. The majority of rear units are equipped with reflex glass which gives an indication from the reflected light thrown on it. The use of reflex materials in conjunction with incandescent lamps is considered desirable from a safety standpoint. Incandescent lamps are being used also to indicate when the engine needs oil and whether or not the battery is being charged.

Present day headlamp equipment, which is mostly of the fixed focus type, is capable of furnishing good road illumination with a minimum of glare but in order to obtain the maximum advantage from this equipment additional educational work is still needed which should be directed along the lines of encouraging car drivers to use the lower or depressed beam when meeting or signaled by oncoming cars.

### *Daylight vs. Artificial Light*

Recently developed lighting equipment provides artificial light with supplementary ultra-violet radiation, exceeding that received from daylight filtered through window glass. This, coupled with improved electrical air conditioning, is rendering building construction independent of natural illumination. In a number of buildings recently completed or under construction, daylight has been purposely excluded.

### *Architectural Relations*

Each year architects show a growing interest in the decorative as well as utilitarian possibilities of modern lighting. The Illuminating Engineering Society, in cooperation with the Beaux-Arts Institute of Design, has established an Illuminating Engineering Society Prize for which architectural students throughout the country compete. This year's project is designing the lighting for an exhibition hall at a world's fair. It is planned to continue this prize competition for the next decade.

The American Institute of Architects is cooperating with the Illuminating Engineering Society in the revision of the American Standard Code of School Lighting.

### *Light Control*

The photoelectric light control relay is a device which regulates automatically the turning on and off of artificial lighting as the intensity of daylight decreases or increases. During the year such control was applied to the lighting of a school room where children in a special "sight-saving" class receive their instruction. Tests conducted in this room indicated that in order to maintain an intensity of 15 foot-candles, it is necessary to use the artificial lights at least 30 per cent of the time the room is in use.

Thyratron control of lighting is being applied to theaters, floodlighting of buildings, show windows, and electric fountains.

Thermionic tubes appear especially applicable for automatic dimming controls, where the only moving part can be small potentiometers or phase shifters actuated by very small motors. Applications of mobile color lighting with these controls include a floodlighted building, dance halls, night clubs, restaurants, and a number of theaters.

One of the most recent developments utilizes a continuous belt for controlling the potentiometer adjustment by providing a conducting path for each color or group of lights to be controlled. Any desired combination can be secured by varying the position of the conducting paths on the belt, so that any predetermined lighting effect can be repeated at will, or a new combination can be secured by "changing the roll." It is reported that the first installation of this arrangement will be to control the lighting of Buckingham Fountain in Chicago.

With the new thermionic tube controls the manual switchboard for theater and stage lighting can be very small, located in the orchestra pit, on the stage, or even in the front rows of the orchestra. Now the "lighting conductor" becomes a reality and the lighting of the show is played by the conductor who sees and hears the entire action.

### *Illuminometer*

A new portable illuminometer employing the photoelectric principle has become available. The photonic cell consists of a disk on which has been deposited light-sensitive material so that, when exposed to light, a slight but apparently constant electrical potential is generated. The readings are made on a microammeter connected to the cell by means of a flexible conductor cord.

For increased deflections two or more cells are sometimes mounted in a single housing and connected in multiple. Measurements and checks under incandescent lighting of the range ordinarily found indoors seem to show comparatively close agreement with the usual types of visual illuminometers.

### *Lighting Plans for 1933 Chicago Fair*

A wide interest and curiosity has been exhibited by the public regarding the illumination of the 1933 Fair. It is not appreciated generally that the interiors of the Fair buildings will have no natural light. They will be illuminated both day and night by electricity. In general there are no windows or other openings through which natural light may enter.

One novelty will be shimmering effects on exterior walls such as is produced by reflection of the sun's rays from bodies of water in the daytime. A lighting projector built upon this principle will be used to throw fantastic moving color patterns on building walls. By agitation of the water in different ways, patterns of various forms may be produced. So-called scintillators will be used also. In this case squares of polished metal trembling on delicate supports will flash dancing color patterns over large areas of frosted glass. This is one of the few lighting effects that can be utilized in the daytime. The rays of the sun are allowed to penetrate the glass at many points and are reflected back by the metal squares in lively fashion, somewhat similar to the heliograph used by the Army for signal purposes.

Fluorescence will be used also. Many objects such as flowers, foliage, statuary, et cetera, will be treated with fluorescent materials and under so-called invisible light will appear in contrast with the surrounding foliage.

The possibility of fluorescent fountains has not been overlooked. There are several organic substances that may be added to water to produce fluorescence, such as eosine, fluorescene, and aesculin. Very small quantities of these substances added to water in a circulating fountain are sufficient to impart a mysterious glow to the water under so-called invisible light.

During the last few months the Fair has been experimenting with a great so-called flaming ladder arc, using a potential of 33,000 volts. Rising from a huge outdoor transformer will be two electrodes about thirty feet high. A flaming arc will start from the bottom of these electrodes and travel upward. As this intense flame dissipates at the top, another automatically starts at the bottom, so that there is a succession of fiery bridges or rungs in constant motion. Hence the term "ladder arc." As these arcs travel upward, dry chemical salts are injected by compressed air. These salts impart changing colors to the arc stream.

### *International Commission on Illumination*

The International Commission on Illumination met in Cambridge, England, the week of September 13, 1931. In connection with the meeting a Congress was held in which meetings assembled in London, Glasgow, Edinburgh, Sheffield, Buxton, and Birmingham. Many notable demonstrations of illumination were made for these events and the subsequent celebration of the Faraday Centenary, among which were the lighting of the public buildings and streets of London and Edinburgh Castle. Excellent progress was made toward international understanding on illumination problems.

A new topic was Aviation Lighting in which international unity is especially important.

## GENERAL

### *Revised Nomenclature and Standards*

During 1931 there has been widely circulated for discussion and criticism a revised set of terms and definitions to supersede the American Standard "Illuminating Engineering Nomenclature and Photometric Standards" issued in 1925. The changes which have resulted from this discussion are largely matters of form rather than of substance. The new edition of the nomenclature will show, therefore, few radical departures from the established practise, but is believed to be somewhat more clear and logical.

### *Primary Standards of Light*

International discussion of fundamental photometric problems has continued and several laboratories abroad are reported to have in progress experimental tests of the form of primary standard proposed by the Bureau of Standards. This standard consists of a refractory tube immersed in molten platinum at its freezing temperature. The tube is so constructed and observed as to be a "complete radiator" or "black body." Its brightness as found at the Bureau of Standards is 58.85 candles per square centimeter. The question of accepting this standard is before the International Commission on Illumination and the International Committee of Weights and Measures, but a decision must await independent confirmation of the Bureau's results by some other national laboratories.

### Death of Thomas A. Edison

The Committee on Production and Application of Light cannot conclude its report without allusion to the passing of the founder of the electric lighting industry. His death on October 18, 1931, was the signal for an expression of worldwide appreciation of the services and of the life of the man whom electrical engineers have held in high regard by reason of his inauguration of electric light and power as a widespread service to the public. Edison passes but his work goes on. He lives in the esteem of those who carry on under the banner which he raised.

# Applications to Mining Work

## ANNUAL REPORT OF THE COMMITTEE ON APPLICATIONS TO MINE WORK*

THE past year has been one of very greatly reduced activity in all classes of mines. New machines and new applications of electricity in mining work have been few and, generally, of a minor nature. There has, of course, been no incentive to force production or to increase the capacity of mines, and labor-saving devices have not been in demand because of an unwillingness on the part of operators to aggravate the bad unemployment situation. However, there have been some installations and devices worthy of comment.

A West Virginia coal mine has installed a passenger elevator to expedite the movement of men in and out of the mine and to relieve the production hoist of this service so that it can continue in its regular duty. This elevator has all of the safety and control features of a high-speed traction-drive office elevator. It handles twenty men per trip in a shaft 347 feet deep at a speed of 450 feet per minute. As this elevator travels in the intake air compartment, the car has certain special structural features to permit an uninterrupted flow of air.

Some companies have found it profitable to operate their mines only at night to secure a lower rate for electric power at the off-peak period. Power economies have also been effected by the use of power demand limiters. An installation of capacitors for power factor correction has shown a return of approximately 7 per cent per month.

Two new electric cap lamps for use in gaseous mines have been developed. One of these, weighing only 63 ounces, gives a beam candlepower of 26 at the beginning of a shift and the other, which weighs only 87 ounces, gives a beam candlepower of 55 at the beginning of the shift. A flood lamp, particularly designed for lighting the face for cutting and loading, gives a beam candlepower of approximately 350. All of these lamps have been approved by the U. S. Bureau of Mines.

Improved performance is being regularly obtained from cutting and loading machines. One operator reports that a cutting machine regularly cuts 1,000 to 1,200 tons in 6 to 7 foot coal in a shift, and that he is regularly obtaining 375 tons per day from his loading machine.

A Western Pennsylvania mine has installed a system of automatic door control, using "the electric eye" as the controlling relay. The mine doors are caused to open and close in proper sequence for either direction of movement of the trip.

A wound-rotor induction motor with direct-current excitation of the primary has been installed as a braking generator to replace mechanical brakes, holding a rope haul trip at proper speed down grade. The high expense of brake maintenance has been practically eliminated.

Several large induction motors and synchronous motors with automatic line-start control have been installed for pumping in the anthracite field. The controls for several of these are housed in cubicles and completely erected at the factory.

A large, high-speed, heavy-duty, variable-voltage hoist, taking its power from a synchronous motor-generator set, has been installed in Canada. The rotating equipment consists of a 1,250-kw. generator, an 1,800-hp., 750-r.p.m. synchronous motor and a 1,550-hp., 68-r.p.m. hoist motor. The skip has a capacity of 6 tons of rock per trip and travels at a speed of 2,200 feet per minute.

A new light-weight self-propelled cutting machine has shown favorable results over several months of trial. The machine has a very high-speed cutter which resembles in its operation a band saw more than the usual type of cutter.

The construction of new coal-cleaning equipment kept pace with progress of previous years in this line. It is estimated that 8,000 tons per hour of complete mechanical cleaning capacity were installed in 1931 in addition to 20,000 tons of capacity for cleaning and sizing. All of these tipples and cleaning plants were, of course, electrically driven.

W. H. Lesser,
C. W. Parkhurst,
F. L. Stone,
J. F. Wiggert,
C. D. Woodward.

# Transmission and Distribution

## ANNUAL REPORT OF COMMITTEE ON POWER TRANSMISSION AND DISTRIBUTION*

THE activities of the Committee on Power Transmission and Distribution have continued through the past year along the lines organized in previous years. Various subjects of interest to the Institute membership have been treated in a number of papers presented before the conventions and district meetings.

A brief outline of the activities of the several subcommittees follows:

### SUBCOMMITTEE ON STEEL TRANSMISSION TOWERS AND CONDUCTORS

Subjects relating to steel towers have been studied and certain items of general interest are now being given particular attention preliminary to the preparation of future reports.

A report has been drafted outlining the requirements for modern steel tower transmission lines which, after review, it is expected will be published. Conductor vibration has been given intensive study. A direct result of this work has been the publishing of a bibliography including all available data on the subject of vibration. A session at the Summer Convention is devoted to this important subject.

### SUBCOMMITTEE ON DISTRIBUTION

Continued consideration has been given to the various broader aspects of distribution, including developments in secondary and primary networks.

Of particular interest to distribution engineers is the symposium presented at the Winter Convention consisting of six papers on distribution circuit lightning protection. This symposium summarized the results of intensive field and laboratory experimental work and analyses of operating experience. It is believed that this material will be productive of improvement in distribution equipment and construction practises and in service reliability.

### SUBCOMMITTEE ON CABLE DEVELOPMENTS

There have been no marked innovations in the cable art during the past year, although study has been continued on the developments indicated in previous reports. In the high voltage transmission cable field, the highest voltage submarine cable crossing in the world, across the Columbia River near Portland, Oregon, is also the first of the oil-filled type used in submarine work. The cables are 750,000-cir. mil., single-conductor, rated at 115 kv., and an insulation thickness of 0.550 inch. An unusual feature is the use of hard-drawn-copper armor wires, instead of the usual steel, in order to reduce the losses in the armor and thereby increase the rating to 114,000 kva.; over 30 per cent more than if steel armor had been utilized.

The performance of experimental installations of 132-kv. cables, one of the oil-filled type with reduced insulation and the other of the solid type, in Chicago and in Newark, respectively, has continued to be successful.

### SUBCOMMITTEE ON INTERCONNECTION AND STABILITY

The joint subcommittee on interconnection is formed from representatives of the Power Generation, Protective Devices and Power Transmission and Distribution committees. During the year the scope of the committee was increased and representatives were added from the Committee on Electrical Machinery.

This joint subcommittee sponsored a session at the Winter Convention on the subject of Decrement Curves and Power System Stability. Two other stability papers were presented during the year.

### SUBCOMMITTEE ON LIGHTNING AND INSULATORS

The necessity for establishing a definite wave or group of waves by which to measure impulse strength of insulators has been recognized for some time. In the interest of greater uniformity in test practises, agreement has been reached on a tentative group of waves (1) which would closely approximate the effects of natural lightning voltages imposed on apparatus connected to transmission systems; (2) which could be produced with available laboratory equipment; and (3) on which considerable impulse data have already been secured by various laboratories which have been investigating the performance of insulation under impulse voltages. The following three waves have been agreed upon as preferred test waves for impulse testing. These waves are designated as $^{1}/_{2}$ x 5, 1 x 10, and $1^{1}/_{2}$ x 40. The first number indicates the microsecond time to crest, and the second number the time in microseconds from zero to 50 per cent of crest on the tail.

Another development in the lightning field has been continued this year in the factory test of commercial transformers with artificial impulse waves. It appears that the manufacturers are now in a position to test commercial transformers in the higher voltage ranges with artificial impulse waves, and a recommendation has been made that a committee formulate the procedure to be followed in applying impulse waves to transformers. This work is already in progress.

**H. S. Warren.**

Field investigation of natural lightning which has been in progress for the last few years has been continued on a decreased scale.

Discrepancies in 60-cycle flashover values of insulators mentioned in last year's report as due to humidity conditions have been further studied this year. Papers fully covering this subject have been presented before the Institute during the year.

Reference has been made above to the field, laboratory, and operating investigations relating particularly to 2,300- and 4,000-volt distribution lightning protection. Of particular interest is the apparent benefit to be derived from interconnecting the primary arrester ground with the secondary neutral, if the latter is well grounded.

### CONCLUSIONS

In conclusion, the committee wishes to express its gratification at the interest evidenced in the field of Power Transmission and Distribution by the papers submitted and by the attendance and discussion when presented.

This interest together with that displayed by the members of the committee, and by those associated in the work of its subcommittees, have made possible the accomplishments of the committee.

# Power Generation

## ANNUAL REPORT OF THE COMMITTEE ON POWER GENERATION*

ALTHOUGH the past year has recorded no major strides in power plant design and construction not heretofore discussed in committee reports, the committee has been successful in obtaining a variety of papers of a critical nature for Institute presentation, surveying present practise, with the object of indicating probable lines of advance when the construction of new or additional power projects again becomes active. Following the custom of preparing progress reports only at biennial intervals, the committee report for the past year will merely recount briefly the results accomplished by the several subcommittees engaged in planning and securing technical papers.

The Joint Interconnection Subcommittee, of which F. C. Hanker served as chairman, was instrumental in presenting at the Winter Convention six papers embracing several phases of the subject of stability of power systems, including that of *Stability of Conowingo Hydroelectric System*, by R. A. Hentz and J. W. Jones. A record of the most recent technical advances in power system design and operation was given in that paper. Another valuable paper concerned the standardization of nomenclature regarding stability, being a report by H. K. Sels.

Another session at the Winter Convention was sponsored by the subcommittee on Power Station Auxiliaries, composed of H. W. Leitch and F. H. Hollister. The comparative merits of steam and electric drives for steam power stations were analyzed in papers by W. Poole Dryer and L. W. Smith, advocating opposing views, and in a summary statement by F. H. Hollister.

A subcommittee headed by N. E. Funk has arranged a symposium of four papers on *Combined Economy and Reliability in Operation of Large Electric Systems*, for the Summer Convention. Current practise in the Boston, Chicago, Detroit, and Philadelphia areas will be discussed at that time.

Other work consisted of a review by I. E. Moultrop and J. B. Crane of the economics of the design and use of high-temperature and high-pressure steam equipment, with a supplementary discussion of the use of welding in modern fabrication methods. A paper on this subject awaits opportunity for presentation. The subcommittee on Hydroelectric Practise, J. P. Hogan, chairman, will offer a paper by A. V. Karpov on *Low-Head Hydroelectric Developments* at a Fall District Meeting featuring other papers on hydroelectric subjects. F. A. Annett of the subcommittee on the Design of New Plants has reviewed papers describing the Waukegan and Ashtabula plants, and has cooperated in having the subject of power generation adequately represented on the program of the Pacific Coast Convention this summer.

The Committee recommends that the recent innovations in the design and application of switching structures at power plants be given major attention during the coming year. For that purpose a subcommittee, A. E. Silver, chairman, was appointed which has been assembling data and information for a discussion of that topic next winter.

The Committee wishes to take this opportunity to record its thanks for the assistance given by the several authors and the many discussers of papers to the end that the progress in the field of Power Generation be adequately reported by the committee.

# General Power Applications

## ANNUAL REPORT OF COMMITTEE ON GENERAL POWER APPLICATIONS*

DURING the past year the committee has not sponsored a session at any of the meetings or conventions, but has reviewed and reported upon a number of industrial papers. Two of these papers were presented at the Pacific Coast convention at Lake Tahoe, August 1931, and as far as we know these were the only industrial papers presented at district meetings before the Institute during the year. These two papers are as follows:

*Electrical Equipment for Oil Field Operations*, by H. C. Hill and J. B. SeLegue

*Electric Power in the Wood Products Industry*, by C. E. Carey and K. L. Howe

Although the general activity of practically all industrial plants and machinery manufacturers has been greatly curtailed during the year, nevertheless, this extremely competitive situation is responsible to some extent for a number of developments and improvements in industrial equipment which have been brought out. Last year we mentioned the interest that was being shown in connection with the use of electronic tubes for industrial applications. The various characteristics which these tubes possess which are not otherwise obtainable are almost daily finding new industrial uses. A large number of these applications falls under the classification of process control and are in line with the trend of the time toward elimination of waste, reduction of cost, an more accurate control of all manufacturing processes Most of these electronic developments are give publicity in the various trade papers or in *Electronics* and to keep posted on such activities constant contact with such literature is necessary. A comprehensive review in a report of this kind is entirely impossible.

During the year considerable attention has been given by various electrical machinery manufacturers to the design and construction of motors, controllers safety switches, push-buttons, and other details to meet the requirements for Class II Hazardous Locations as defined by the Underwriters' Laboratory. Such equipment, although required for such locations in flour mills, grain elevators, starch plants, coal pulverizing plants, etc., finds numerous other desirable applications where its installation results in lower maintenance cost and improved operating conditions.

Instead of attempting to abstract information regarding the numerous developments in industrial apparatus or application, the committee feels that members interested in such equipment can readily obtain such information directly and more completely from the various periodicals as, for instance, *The Electrical World*, *Maintenance Engineering*, *G. E. Review* or *Electric Journal*, together with the various specific industry magazines. The January issue of such magazines generally contains a review of the year's achievements in a much more complete and interesting form than could be given in a report of this kind.

W. K. Vanderpoel,
M. R. Woodward.

# Iron and Steel Production

## ANNUAL REPORT OF COMMITTEE ON APPLICATIONS TO IRON AND STEEL PRODUCTION*

### GENERAL

IT is estimated that the steel industry expended approximately 35 million dollars in 1931 for the purchase and installation of new apparatus, the maintenance of old equipment, and in the purchase or generation of electric power.

During the year there were purchased 63 main-drive motors of more than 300 rated hp. each. The total rated horsepower of these drives aggregated 119,325 hp. These figures compare with the installation of 163,490 hp. which occurred in the year 1930.

A major trend toward increased use of refined control equipment for automatically performing tasks which had previously required manual labor was continued during this year. While such equipment was installed at a reduced rate in 1931, the percentage of men whose duties were no longer required in the steel industry due to such automatic devices increased.

H. A. Winne.

### MAIN AND AUXILIARY DRIVES

The 44-inch universal slabbing mill in the Chicago District, referred to in last year's report as being under construction, was completed during the early part of 1931. The upper and lower main horizontal rolls are driven by two 5,000-hp., 40/80-r.p.m., 700-volt, double-armature reversing motors; and the auxiliary vertical rolls are driven by a 2,500-hp., 79/225-r.p.m., 700-volt, single-armature reversing motor. The total continuous capacity of the three motors is 12,500 hp., and the maximum emergency capacity about 35,000 hp., nearly a third greater than any similar mill. The three motors are connected in parallel and are supplied with variable-voltage direct-current power from a 10,500-kw., 5-unit, six-bearing flywheel motor-generator set, consisting of three 3,500-kw., 700-volt generators, a 6,500-hp., three-phase, 25-cycle, 6,600-volt, 370-r.p.m. wound-rotor induction motor and a 180,000-lb. flywheel. When running at synchronous speed, the total stored energy in the rotating parts of the motor-generator set is approximately 270,000 hp-seconds. Latest operating data indicate this installation has proved quite successful.

A recent installation of induction motors and control for operating "catcher tables" has fulfilled the expectations of not only the operators, but of the mill designers and electrical manufacturers as well. These tables are used in the rolling of sheet steel and take the place of the older manual methods of handling the sheets and packs during the rolling process. The cycle of operations includes carrying the material into the mill by means of the roller table, receiving it on the catcher table, tilting the tables upward, transferring the sheet over the top roll back to the roller table, returning the tables to the down position, and reversing the direction of travel back into the mill. This cycle of operation must be completed under some circumstances in three seconds, which means that the motors must be capable of reversing or starting at the rate of 40 times per minute.

Special low-inertia, low-speed motors have been developed to cover this type of application. The speeds used are 375 r.p.m. for 25-cycle supply and 450-r. p. m. for 60-cycle supply. The use of squirrel-cage motors for such duties as this has been attempted only within the past two years, but it is an indication of the changing trend toward the application of simplified motor and control apparatus. Formerly, direct-current mill-type motors were thought the only solution for such problems.

During 1931, the first American installation for producing seamless steel tubes by the "push bench method" was completed. In the production of seamless steel tubing by this method, a heated blank is placed in a hydraulic press and formed into the shape of a thick walled thimble. The thimble is then placed on the end of a mandrel and forced through a series of stationary ring dies, which gradually decreases the wall thickness, and at the same time elongates the thimble, thus forming a long tube with a closed end. After the elongated thimble has been forced by the mandrel through the various dies, the mandrel is withdrawn and the closed end of the tube sawed off. Sizing and finishing is carried on subsequently in mills of the usual design. The power required on this application is approximately the same as that used by the piercing process.

In the installation just completed, the mandrel is forced forward through the dies by means of a rack and pinion which is driven by a 1,500-hp. variable-speed d-c. reversing motor. The control for this equipment is so arranged that upon indications from the operator, the motor will start, accelerate the ram, force the material through the dies at a predetermined rate of speed, then stop, reverse, and return the mandrel to the initial position. Means are provided for adjusting the speed of the stroke over a wide range, and extremely fast acceleration and retardation are necessary to meet the operating cycle. Devices are arranged in connection with this control to prevent the ram from overrunning in either direction. The manufacture of tubes by this process is expected to produce a small seamless tube at very low cost and for this reason it is probable that additional installations of similar equipment will follow.

Two steam engine drives in the Pittsburgh District were replaced by motor drives. A three-high roughing mill driven by a 1,500-hp. steam engine has been re-equipped with a 1,600-hp. wound-rotor induction motor. Likewise a reversing steam engine on a two-high finishing mill has been replaced by a 1,250-hp., d-c. reversing motor. This reversing equipment is said to be one of the smallest applications in the steel industry of reversing main roll drive equipment.

There have been two major hot strip mill installations made during the year. One of these consists of a 72-inch continuous hot strip mill and the other a 76-inch continuous hot strip mill. It is understood that both of these mills are equipped with anti-friction bearings on the main rolls throughout, and combine the use of induction motors on the preliminary stands, synchronous motors on the intermediate stands and d-c. adjustable-speed motors on the finishing stands. It is unusual to find the three types of main roll drive combined in one mill installation, but it was possible on these particular mills to secure the necessary relations between peripheral roll speeds without the use of expensive adjustable-speed d-c. drives throughout the entire mill.

The largest motor equipment ever sold for driving a cold strip mill was also installed during the year. Each of the two stands of this cold strip mill are driven by a 1,500-hp. adjustable-speed, d-c. motor. A tension reel driven by a 400-hp., adjustable-speed, d-c. motor, receives the material from the two cold roll stands. It is apparent that the year has witnessed a change in the electrical equipment used in the rolling of both hot and cold strip.

New designs of electric contactors were announced by one of the leading manufacturers during the year. Decided progress was made by a committee of steel mill engineers toward the standardization of control equipment. It is felt that it will be but a short time until a satisfactory steel mill control standard will be an accomplished fact.

Several new tension-limiting devices were designed.

for automatic reeling applications. Some are designed to place a predetermined tension on reels coiling strips after they are rolled, while others are between stands of the finishing passes. Automatic screw-down equipment for two-high and universal mills of simplified design appeared. This apparatus uses electron tubes to replace cumbersome limit switches. However, no installations of this type of screw-down control have been completed at the time this is written. Automatic screw-down control assures uniformity in rolling practise, independent of the whim of the operators, and has resulted in a material improvement in the quality of the product of rolling mills where it has been in service. The apparatus used in the past has been quite complicated and it is felt that the new devices tending to simplify this type of equipment will prove to be a worth while development and result in more general use.

## SYNCHRONOUS MOTOR CONTROL

The recent remarkable increase in the use of synchronous motors in steel mills has made their characteristics, operation, and control a subject of great interest to steel mill electrical engineers. The favorable status of the modern synchronous motor was not achieved, however, until definite limitations of the earlier designs were overcome. Modern design and construction have removed most of these earlier limitations until now the synchronous motor starting, pull-in, and pull-out torques are exceptionally favorable for applications heretofore reserved for induction and direct-current motors.

A recent development of unusual interest has taken place in control systems for synchronous motors. This development is the culmination of investigations started many years ago which have done much to extend the field of application of the synchronous type motor. Recent systems of control automatically start the motors under the best conditions, in the shortest time, and keep them running through nearly all power supply disturbances of a transient nature. In short, modern synchronous motor control eliminates many of the starting and operating difficulties, which prevented their extensive acceptance in industrial fields.

Modern synchronous motor-control systems comprise the following separate features:

1. Part winding starting, resulting in reduced starting kva.
2. Transfer to full voltage by means responsive to the electrical condition of the field winding.
3. Synchronizing by means responsive to the electrical condition of the field winding.
4. Delayed low-voltage release.
5. Field kick-off and resynchronizing (where the load permits).
6. Unloading and reapplication of load to driven machine.

Not all of these features are required for every application, but those are employed that accomplish best possible starting under all conditions and continuous operation through momentary power or load disturbances.

## ELECTRIC FURNACES

Several installations of electric furnaces for bright annealing coiled steel strip were completed and placed in operation during the year. Each furnace consists of a bell type heating chamber and several bases or cars upon which the coiled strip is stacked. An inner hood or cover of heat-resisting alloy is placed over the stack and serves to exclude air both during the heating period and while the coils are being cooled. An atmosphere of illuminating gas or other suitable gas is maintained under the hoods to prevent oxidation.

A new type of furnace, applicable especially to annealing steel sheets, has been developed in which a load of material can be cooled in the furnace in a comparatively short time. With previous types, the cooling rate of a loaded furnace is so slow as to make furnace cooling impracticable. The new furnace is lined with light weight refractory brick so that the heat storage in the furnace walls is comparatively small. It employs a circulating system for the furnace atmosphere, with an external cooler by means of which the heat may be extracted and the furnace again charged at a more expeditious rate than was possible heretofore.

## MATERIAL HANDLING

There has been installed in the Pittsburgh District a large ore bridge using a bucket of 17 tons capacity. The bridge span is approximately 190 ft. The outstanding feature of the bridge is the unusual use of compressed air for control. Ten motors, 275 to $7^1/_2$ hp., are controlled by electropneumatic type control, similar in design to standard railway equipment. This arrangement, it was found, required less space and lower maintenance. The brakes are spring set and air released for quick, positive stopping. Due to the large volume of air required, there are three sets of compressors and reservoirs, one in the operating cab and one in each leg of the bridge. The bridge in normal service can handle 1,000 tons an hour and serves several blast furnaces located nearby.

## ELECTRONIC DEVICES IN THE STEEL INDUSTRY

The past year has seen a rapid increase in the number, diversity, and ingenuity of applications of electronic devices in the iron and steel industry. These devices are now controlling shears, soaking pit covers, repeaters, and various mill table operations.

In one plant, a flying shear is located between the intermediate and finishing stands of a 10-inch hot strip mill. This shear is to cut off the relatively cool front end of the bar before it enters the finishing stands. Formerly an operator was necessary to trip the shear when the strip was in the proper position, so as to cut off a definite crop length. Now a photoelectric tube automatically trips the shear. An adjustable time-delay relay is used to determine the time interval between the interruption of the beam of light and the starting of the shear, thus compensating for the changes in the strip speed.

In another plant, considerable trouble was encountered in maintaining a flag switch on a back blooming mill table, used to control the operation of a recording pyrometer. A photoelectric tube with the required amplifier unit and relays now performs the operation in a more reliable and accurate manner.

Several installations have been made which permit crane operators to control heating furnace doors by means of photoelectric equipment. A number of other steel mill applications of photoelectric devices have been made, such as skip-hoist limit stops, stock-bin level indicators, spotting of material in reheating furnaces, pyrometers, etc.

. . . .

All in all, 1931 has, in spite of adverse conditions, brought into being a number of new ideas and electrical developments in the iron and steel industry. Cooperative exchange of information has continued, and permitted the industry to benefit from individual as well as collective effort and development.

The Chairman wishes to express his appreciation for the assistance rendered by the members of the committee in the preparation of this report.

### Bibliography

The committee submits a list of the principal papers that have been presented or published by various engineering societies covering more completely many of the subjects reviewed in this report.

1. "Twin Motor Drive," R. H. Wright and H. E. Stokes, *Iron and Steel Engineer*, June 1931, Page 246.
2. "Motor and Control Equipment," F. Mohler, *Iron and Steel Engineer*, June 1931, Page 272.
3. "The Hibbard Control System and Its Application to Synchronous Motors in Steel Mills," W. H. Feldman and S. P. Bordeau, *Iron and Steel Engineer*, December 1931, Page 483.

# Communication

## ANNUAL REPORT OF COMMITTEE ON COMMUNICATION*

### COMMITTEE AFFAIRS

THE Committee on Communication continued the practise of outlining at the beginning of the Institute year tentative communication programs for each of the subsequent scheduled Institute meetings. In making up the year's outline, the Committee strove to select material which would be of broad interest to the Institute as a whole and, in particular, to foster the presentation of papers on subjects that had not been covered before or that had received but little recent attention. A successful endeavor was made to cover such subjects in a rather complete and thorough way. The advance planning of programs greatly aided this by allowing the Committee ample time to solicit authoritative papers discussing all the major aspects of each subject selected for extended treatment.

The more important groups of coordinated papers which in accordance with this general policy have been presented at Institute meetings during the past year are:

*Symposium on Communication Services for Power Companies*—1931 Summer Convention:

This was prepared with the cooperation of the Committee on Transmission and Distribution and is headed by a general review of the subject prepared by a joint subcommittee of the Committee on Communication and the Committee on Transmission and Distribution, followed by a group of individual papers prepared by power and communication engineers, discussing the solution of this problem in specific cases.

*Symposium on Time and Time Services*—1932 Winter Convention:

This is headed by two papers discussing the astronomical aspects of time and its measurement, followed by discussions of the time services given by the Naval Observatory, the telegraph companies, and the power companies. In arranging this symposium the Committee on Communication had the cooperation of the Committee on Transmission and Distribution.

*Symposium on Traffic Control*—Northeastern District Meeting, May 1932:

This is headed by a general discussion of traffic control followed by papers describing various electrical systems now having important fields of application.

*Planning for Telephone Toll Service*—Southwestern District Meeting, October 1931:

---

* COMMITTEE ON COMMUNICATION:

H. S. Osborne, Chairman,
E. J. O'Connell, Secretary,
H. M. Bascom,
E. L. Bowles,
W. H. Capen,
A. A. Clokey,
R. N. Conwell,
C. F. Craig,
B. R. Cummings,
R. D. Evans,
I. C. Forshee,
D. H. Gage,
B. D. Hull,
T. Johnson, Jr.,
G. M. Keenan,
G. A. Kositzky,
C. J. Larsen,
John Mills,
J. W. Milnor,
C. W. Mitchell,
F. A. Raymond,
H. A. Shepard,
E. R. Shute,
A. L. Stadermann,
C. H. Taylor,
H. M. Turner,
F. A. Wolff.

A group of three papers discussing, respectively, the forecasting of population, the general advance planning of telephone toll facilities, and certain technical problems involved in their design.

In addition, a number of individual papers has been presented under the auspices of the Committee at various national and regional meetings during the year, discussing important phases of new developments in the telephone, telegraph, and radio arts. The total number of communication papers, including the symposiums, presented at these meetings during the year was 33.

The communication sessions have been very well attended. The Communication Committee proposes to continue during the coming year its plan of developing programs involving groups of coordinated papers covering subjects of broad general interest.

## ADVANCE OF THE ART

In line with the aim to keep this report as short as practicable there are listed below only a few of the outstanding advances made in the field of communication last year.

During the year the Bell System introduced teletypewriter exchange service whereby any subscriber to this new service may secure a direct connection to any other subscriber over which the two may carry on instantaneously reproduced two-way typewritten communication with one another. The methods and switching equipment employed in establishing connections are similar to those employed in telephone practise.

Also during the year the Western Union Telegraph Company and the Postal Telegraph-Cable Company jointly inaugurated a new form of telegraph service known as "Timed Wire Service." This is available to customers who have simplex printers, and provides for the transmission of communications from any printer to any other at rates based on the time the facilities are in use, rather than on the number of words transmitted. Printer customers desiring this service will obtain connection at the central office with an automatic reperforator, which will directly prepare a perforated tape in form for retransmission to the city of destination without additional manual handling. At this point a second perforated tape will be automatically prepared and used for retransmitting the message to the customer addressed. The service is somewhat analogous to a one-way private wire connection, although a direct connection is not established. The Timed Wire Service routine permits of a more economical utilization of the trunk wire plant than would be possible were a direct connection of printers established.

An automatic concentrator was developed for use on printing telegraph circuits to provide faster and more economical service on customers' lines. The Postal Telegraph Company has installed several of these equipments.

A four-wire voice-frequency carrier telegraph system adapted to meet the requirements of a strictly telegraph plant was developed and an initial installation was made on the lines of the Postal Telegraph Company.

A new cable and radio operating center, serving jointly the Commercial Cable Company, the Mackay Cable and Telegraph Company, and All America Cables, was placed in operation last year. Circuits linking the United States with Europe, Central and South America, and the Far East terminate in this center and connect 85,000 miles of under-sea telegraph wires through 19 separate channels. Three cables to Central and South America and two New York-London cables have been equipped with recently developed printer apparatus which has greatly increased the accuracy of reception and has also effected substantial economies. A recently developed method for converting the non-uniform length signals of the Cable Morse Code into a modified 5-unit code, so as to permit of the operation of printers on long non-loaded submarine cables, is employed in connection with these printers.

A pneumatic tube carrier routing device has been developed by the Western Union Telegraph Company for automatically selecting and diverting tube carriers from a main tube into the proper branch tubes. Pneumatic tubes are used to carry telegrams between main and branch offices and between points in large main offices.

Recent achievements in cable making have included the standardization of cables of less than 1,800 pairs employing 26-gage wires, and the application of a new process of insulating small-gage conductors for exchange cables. Under the new method of insulating the cable wires, a coating of wood pulp is applied to each conductor from a bath of water-suspended pulp. This coating when it dries becomes a continuous uniform sleeve of porous paper surrounding the wire. Cables made from this material are of the same size and have practically the same operating characteristics as cables of the older type, for which wires are insulated by helical wrappings of thin, narrow manila paper ribbon. Four machines for producing pulp-insulated wire were placed in operation last year with an output capacity of about 200,000,000 feet of wire a week.

Bermuda, Hawaii, Rio de Janeiro, Java, Sumatra, and the Canary Islands were brought into telephone communication with the interconnected telephone system of North America by means of radio links established in the past year. The first three places are reached by direct radio circuits from the United States. Communication between the sending and receiving stations at Oahu, and the other islands of the Hawaiian archipelago, is secured by an ultra-high-frequency radiotelephone system put into service by the Mutual Telephone Company. This system is also used regularly in inter-island telephone service.

Single side-band transmission of short-wave radiotelephony was successfully demonstrated by the International Telephone and Telegraph Laboratories. The spread side-band system for use on short-wave radio telephone links has also been developed by means of which distortion effects due to selective fading can be largely eliminated. By an extension of the principles involved, a number of side bands can be placed on one carrier in such relative positions to each other and the carrier that harmonic distortion as well as crosstalk between channels is eliminated.

A successful demonstration of two-way radiotelephony on an 18-cm. wavelength was given across the English Channel by the International Telephone and Telegraph Laboratories. This system, called "micro-ray," employs an antenna only 2 cm. in length. The greater directivity of these short waves makes it possible to employ the same wavelength for a number of separate channels closely spaced as to geographical separation, without mutual interference. Because of this, and the wide frequency band thus opened up, the commercial application of the "micro-ray" would make available nearly a quarter of a million additional radio channels.

Improvements have been made during the year in controllers for pre-timed traffic signals. One type is arranged so that signals may be automatically operated on different time cycles at different periods of the day or week. Another type is primarily intended to operate in connection with a flexible progressive system, but may be also used to meet the special requirements of detached street intersections. This provides for several functions in addition to the usual automatic stop-and-go control: manual control, flashing amber on one street and flashing red on the cross streets; lengthened green on the main street, pedestrian period, fire lane at one or more of the intersections and varying go periods at different intersections, while preserving the total cycle for progression.

# Cleveland Repeats Its Invitation

## To the Annual Summer Convention, June 20-24, 1932

**The committees are working hard to assure you a profitable and entertaining visit. No registration fee.**

Cleveland Museum of Art, inspection of which is included in the ladies' entertainment program for Monday, June 20, 1932

Canterbury Country Club, where play for the golf tournament will start on Monday, June 20. A new trophy has been provided by Past-President R. D. Mershon to take the place of the time-honored Mershon trophy which was permanently won last year, and a new trophy has been given by Past-President W. S. Lee. A large number of prizes, including four trophies for an A.I.E.E. District team competition, will be provided by the local sports committee.

# Industrial Notes

**Air Conditioning Department for G-E.**—The organization of an air conditioning department within the General Electric Company, which will market various electrical devices for home heating, humidifying, and temperature control, has been effected, and one of the first products to be marketed by this new department will be a complete oil burning furnace. J. J. Donovan, of Cleveland, formerly in charge of apartment house refrigeration sales, will be manager. Associated with him will be E. D. Harrington, of Schenectady, in charge of application engineering; J. R. Rue, of Pittsfield, in charge of manufacturing, and H. S. Woodruff, of Schenectady, in charge of design engineering. Headquarters will be maintained at General Electric's New York offices, 120 Broadway.

**American Steel & Wire Company Opens New Warehouse.**—A new Chicago warehouse located at 2364 South Ashland Avenue is announced by the American Steel & Wire Company. The new depot supplants the Lake Street site and has the distinct advantage of a near south side location.

**New Lifting Magnet.**—The Electric Controller & Mfg. Co., 2700 East 79th St., Cleveland, Ohio, announces a new size, heavy duty lifting magnet known as the No. 3½ type SA magnet. The new magnet is an intermediate size and intended for use with overhead, crawler, or other type cranes in foundries, scrapyards, etc. It requires a 5 kw., direct-current generator.

**A New Dead-End Clamp.**—The Ohio Brass Company, Mansfield, Ohio, has developed a new universal strain clamp to meet the need for a small, inexpensive dead-end clamp. It is designed especially for use in stringing distribution lines, substation buses, low current transmission lines, and overhead ground wires. Although of light weight, this new clamp will develop an ultimate of at least 10,000 pounds. High slip strength is provided by the "V" shaped seat and by the curvature of the clamp body. All conductors for which the clamp is designed are held securely in its grip. By means of a reversible keeper piece, A.C.S.R. or copper conductors from No. 6 to 4/0 may be accommodated. Clamps are supplied with or without a ball and socket eye. The clevis of the clamp may be connected directly to any of the other standard O-B clevis type suspension insulators and hardware.

**Stibloy Now Produced by New Koppers Company.**—The Stibloy Products Company, Inc., with principal offices in the Koppers Building, Pittsburgh, has taken over the assets of Liquid Metal Products, Inc., Chicago, producers and distributors, under the Arent patents, of Stibloy, a metal compound in liquid form, which acts as a primary coating to hold paint, enamel, and lacquer tenaciously, permitting immediate finishing of new galvanized metal surfaces. Stibloy was developed to extend the life of galvanized surfaces by protecting them from the effects of atmospheric conditions and from the damage caused by exposure to gases, acid fumes, smoke, and brine. It is used for protecting galvanized roofing, fences, screens, transmission towers, substations, and other galvanized products. Officers of the Stibloy Products Company, Inc., control of which has been acquired by the Koppers Products Company, are: president, J. N. Forker; vice-president, S. H. Bell; secretary, John D. Shaner; and treasurer, S. T. Brown.

**New Multiple-Duct Concrete Conduits.**—Two new designs of multiple-duct concrete conduits for underground high tension power cables and low tension telephone cables have been perfected by the McCracken Machinery Company, Sioux City, Iowa, which also produces equipment for their automatic manufacture. The concrete units are said to be non-fusible, with extremely smooth interiors, made in four-foot lengths, and the concrete, when adequately cured, develops a crushing strength of over 4,000 pounds per square inch, with less than 8 per cent absorption and waterproof resistance against 15 pounds hydrostatic pressure. For low tension lines the complete unit joint is grouted to prevent water filtration, but the ducts within the unit are not jointed. For high tension cables each duct is jointed independently. The extreme heat of short circuiting will not fuse the concrete, and the danger of a burnout damaging neighboring lines is said to be remote. The units are low in production cost as the manufacturing machine has a capacity of 30 duct-feet per minute of 6-way conduit, 20 duct-feet of 4-way conduit, and 10 duct-feet of 2-way conduit. Installation costs are reduced because narrower trenches will serve, joints are cemented before being placed in position, no extra excavation is needed to allow for plastering joints, and the units are laid at greater speed. The new multiple-duct type conduit has been adopted for important work in Uruguay by the International Telephone and Telegraph Company.

# Trade Literature

**Circuit Breakers.**—Catalog 5, 16 pp. Describes Roller-Smith air circuit breakers, both open and enclosed; attachments and accessories of all kinds; relays and sectional steel, dead-front switchboards and cubicles. A complete line of the latter is offered and such switchboards may be made up of air circuit breakers, oil circuit breakers, indicating and recording instruments, dead-front knife switches or combinations of all four. Roller-Smith Co., 12 Park Pl., New York.

**High Voltage Testing Equipment.**—Bulletin GEA-1168A, 12 pp. Describes standard apparatus for making high potential tests on insulating oil, bushings, and solid dielectric material, and for conducting high voltage investigations. General Electric Co., Schenectady, N. Y.

**Fuse Links.**—Bulletin, 4 pp. Describes the "Bi-Metal" fuse link, a new development in fast blowing, low temperature fuse links for expulsion cutouts. Line Material Co., So. Milwaukee, Wis.

**Floodlighting.**—Bulletin 777, 28 pp. Describes various principles of floodlighting and includes numerous photographs of different types of installations. A simple method of planning floodlighting is outlined. Curtis Lighting, Inc., 1123 W. Jackson Blvd., Chicago, Ill.

**Diverter Pole Generator.**—Bulletin 55, 4 pp. Describes Diverter Pole generators for charging motive power batteries, which meet the standard specifications of the Electric Truck Manufacturers Association. The Electric Products Co., 1725 Clarkstone Rd., Cleveland, Ohio.

**Testing Machines.**—Bulletin 28, 36 pp. Describes hydraulic testing equipment for determining the physical properties of materials. Contains illustrations of typical installations, including the four million pound machine recently shipped to the University of California, claimed to be the largest universal testing machine in the world. Baldwin-Southwark Corporation, Philadelphia, Penna.

**Meter Test Kits.**—Bulletin. Describes types KS and KF meter test kits. Specifications—25 ampere capacity; light load current controlled by four toggle switches in fixed steps totaling 2½ amperes; full load current between 2½ and 25 amperes is controlled by rheostats, which provide a means for readily compensating for any variation in external impedance. A handy current indicator shows the current reading while the load is in use. The States Co., New Park Ave., Hartford, Conn.

**"De-ion" Circuit Breakers.**—Bulletin C1939, 8 pp. Contains a general description of a new line of "De-ion" circuit breakers. These breakers use a new method of arc extinction that enables elimination of all fuses in panel boards, distribution switchboards within the breakers' capacity and industrial applications where fused safety switches are now used. Bulletin C1937 describes construction and application details of the 225-ampere breaker. Westinghouse Elec. & Mfg. Co., East Pittsburgh, Penna.

**Specifications for Butt-Treatment of Poles.**—Bulletin, 4 pp. Contains specifications for the butt-treatment of Western red and Northern white cedar poles, incised process (Pentrex), as adopted by the Western Red Cedar Association and the Northern White Cedar Association. Bulletin, 2 pp., includes the specifications for the "B" process (no specific penetration guaranteed). Bulletin, 2 pp. Describes "AA" process (no specific penetration guaranteed). Naugle Pole & Tie Co., So. Wabash Ave., Chicago, Ill.

C. E. SKINNER whose term as president of the A.I.E.E. expires July 31, 1932, outlined some of the difficulties facing the Institute and electrical engineers in general today, in his summer convention address at Cleveland. Speaking of present economic conditions President Skinner said "...there seems to be a widespread feeling that relief must come through the application of the engineering method." *p. 472–476*

PAPERS presented at the District meeting held May 4–7, in Providence, R. I., elicited the usual amount of discussion. Papers dealing with induction motors were especially well discussed. *p. 524–525*

THOSE who will spend their vacation attending the 1932 Pacific Coast convention to be held in Vancouver, B. C., August 30 to September 2, will find that the committees have spared no effort to make their visits both highly profitable and extremely enjoyable. *p. 518–519*

MEMBERS of the Institute and subscribers continue to make use of ELECTRICAL ENGINEERING's open forum, the "Letters to the Editor" columns. Discussions of a variety of topics may be found in this issue. *p. 527*

BREAKAGE of conductors on electric power transmission lines formerly attributed to crystallization of the conductor material now is charged to mechanical vibration. The first of two articles dealing with this problem describes laboratory tests made for the purpose of studying the nature of this phenomena, and means of combating it. *p. 482–487*

TELETYPEWRITER communication is used to a large extent in collecting and disseminating meteorological data along with principal airways of the United States. This service, of which a large portion is provided by the government, is used also for plane dispatching and other matters incidental to the operation of the country's airways. *p. 492–496*

NEW OFFICERS elected recently to serve the Institute for the year 1932–33 were announced at the summer convention. *p. 517*

INDUSTRIAL MANAGEMENT and engineering are twin brothers; they have developed together. So states an authority on engineering education in discussing the educational aspects of engineering and management. *p. 476–481*

BEHAVIOR of the plate and grid currents in a grid-controlled mercury-vapor tube may inhibit the proper functioning of the tube. This is one of the findings of a series of tests on a typical tube of this type. *p. 500–505*

CALORIMETER tests on a large hydro generator show that the stray losses measured under load conditions are practically the same as those measured by the conventional short circuit methods. *p. 497–500*

IMPROVEMENTS in the design of single-phase commutating type railway motors have made it possible to design simpler, lighter, and less expensive a-c. locomotives for the Pennsylvania's New York-Washington electrification than had been used previously on that road. *p. 488–492*

IN THE PAST many of the data for comparable porcelain insulators for use on electric power transmission lines seemed conflicting. A closer agreement among the different manufacturers is indicated, however, in a group of three articles covering recent studies conducted in this highly important field. *p. 505–516*

TO CALL the 1932 A.I.E.E. summer convention just concluded in Cleveland, Ohio, an unqualified success is no mistake. The technical sessions were maintained at their usual high standard; the sports events, always important parts of the summer convention, were "top notchers" as usual; many matters of importance to the Institute were considered at both the annual meeting, and the conference of officers, delegates, and members. *p. 520–523*

# The Engineer in a Changing Society

An outstanding article is presented herewith. It is the address given on June 21, 1932, by Doctor Wickenden during a special session of the recently completed forty-eighth annual summer convention of the Institute in Cleveland, Ohio. Its message is of tremendous importance to engineers and to society. —Editors.

**WILLIAM E. WICKENDEN**
MEMBER A.I.E.E.
President, Case School of Applied Science, Cleveland, Ohio

IN THE DRAMA of civilization, the engineer suddenly finds himself called from manipulating the properties in the back-scene and the wings to play a leading rôle in the center of the stage, and the public is not yet sure whether he is the hero or the villain of the piece. The old-line actors who have been thrust into secondary rôles are saying contemptuous things. "This newcomer—he is a mere upstart, with no traditions; he is a hard-minded fellow, without refined sensibilities; he reduces everything he touches to hard and fast quantities, as if the problems of life could be solved on a slide-rule and an adding machine; he cares nothing for beauty and serenity; he fills our cities with noise and ugliness and the countryside with grime and waste; he standardizes all that he touches; he makes robots out of men by day, and fondly imagines that he can turn them back into men after working hours by giving them bathtubs, radios, and cheap automobiles. This fellow is a philistine, with no love for the human spirit."

It is hard to cast the engineer of today into the mold of a hero. No modern Virgil has quite dared to begin an epic "Tools and the man I sing," but then Aeneas had plenty of time to become a legendary figure before Virgil took him in hand. Just at the moment heroes are out of fashion, anyway. The echoes of the greatest war in history are barely stilled, and not one military idol has a pedestal. Foch retires in simple dignity to write his memoirs; Hindenburg hangs up his saber and goes to work for the Fatherland; and Pershing remains the best tailored general in retirement. Shades of Wellington and U. S. Grant! Heroes are out of fashion.

Some of our contemporaries, wearied by the shocks of revolution and transition, are feeling homesick for the middle ages. They would like to see us back in the thirteenth century again, building Gothic cathedrals for the sheer joy of faith and love of beauty. That was the day for heroes, only then men called them saints. Seen from afar, what a simple and unified life that was, with no cross-purposes, no complexes, and no frustrations. Human life and society had but one aim, one ideal, one value, one goal, and that the life beyond. The attainment of sainthood, if not in this world at least in the next, was the goal of all striving. All work was religious work and every calling had its patron saint. Many of the saints seem to have won their halos by reputed services in making crops to flourish, in driving away pests or in warding off epidemics. Perhaps our scientists and inventors are 6 centuries too late. Pasteur, Lister, Edison, and Marconi would most certainly have been canonized, and perhaps even a special day set in the calendar for the veneration of Saint Henry Ford.

Geniuses, it would seem, have been growing either more rare or more commonplace under the blighting touch of science. Who in these 3 centuries since Galileo dares to measure his stature with a Moses, a Homer, an Alexander, a Plato, a Jesus, a Michael Angelo, or a Shakespeare? The essence of modernity is that progress no longer waits on genius; instead we have learned to put our faith in the processes of research and the organized cooperation of ordinary men. To the ancients the pursuit of knowledge was like placer mining—a pursuit for solitary prospectors. Nuggets of truth were found occasionally, and sometimes in a fairly pure state. It would seem that these nuggets were more often hoarded than milled into the coinage of common knowledge. Very often the nuggets were lost or forgotten, waiting a thousand years to be rediscovered. Three centuries before Christ, Aristarchus undertook to measure the distances separating the earth from the moon and the sun, and posited the earth's revolution about the latter. Shortly after an Alexandrian Greek, Eratosthenes, proved the earth to be a sphere and actually measured its diameter within a scant 50 miles of error. Yet none of this knowledge availed to keep Galileo from threat of torture and excommunication.

## SCIENCE BECOMES POWERFUL

Man began to subdue nature and to transform his world when—about 3 centuries ago—he began to mine the hidden veins of knowledge systematically, when he learned not only to recognize truth in its free state, but to separate the finely dispersed gold from the baser ore of common experience, by measurement, by experiment, by hypothesis, and by verification.

Science became powerful when it became cumulative, when observers began to keep detailed records, to publish their findings to the world, to organize co-operating groups in order to pool and criticize their experiences. Science became powerful when its gold was no longer hoarded but was coined into everyday knowledge and use.

## SCIENCE A DIVISION OF KNOWLEDGE

Science, too, owes much to the principle of division of labor. Francis Bacon, who by profession was Lord Chancellor of England, was able to claim all knowledge as his sphere in the sixteenth century. Effective science began when it passed from the occasional amateur into the hands of men who made the winning of knowledge their special function or profession. At once these men began to break knowledge up into smaller and smaller fragments, in order to pursue it more intensively. Recently ex-Senator Pepper, of our neighboring state of Pennsylvania, made this contrast between the specialism of science and the generalism of philosophy the subject of a clever epigram. Scientists, he observes, are men who learn more and more about less and less till they end by knowing everything about nothing; while philosophers learn less and less about more and more until they know nothing about everything. In any well-balanced educational program science needs the compensating values of philosophy and art, because of this fragmentizing of nature and experience.

## GROUP EFFORT, NOT INDIVIDUAL, BECOMES IMPORTANT

As science has become more dominant in human activity, the reign of genius has begun to fade. Though rich in great names, the annals of science are strikingly devoid of towering figures. Science grows by accumulation rather than by brilliant and unpredictable strokes of genius. Its victories belong to the army of patient investigators in sequestered laboratories, rather than to some rare Napoleon of the lecture platform. Its ideal is that of removing the hazards of chance from progress. The key to the technological revolution of the last century is not in individual wizardry, nor in genius appearing suddenly like a prophet from the wilderness; it is to be found in the capacity which men have developed to work in organized groups, developing their leadership from within.

It is this ideal of progress through cumulative effort rather than through genius—progress by organized effort, progress which does not wait for some brilliant stroke, some lucky discovery, or the advent of some superman, which marks the chief contribution of science to social philosophy. The results are brilliant, but they fail to satisfy the instinct of hero-worship. "Arms and the man I sing," chants Virgil in heroic meters to celebrate an age gorgeous in color and romance. The machine age leaves the poet mute, or if he does attempt a song it is in a minor key like Masefield's "Life's a long headache in a noisy street."

## SCIENCE IS NEW, MAN IS OLD

Much of our confusion about the social values of science and its technical uses appears to arise from the fact that our instincts and our circumstances have gotten several centuries out of step. We have a million years of pre-civilized experience imbedded in our nervous systems and our emotions, an experience dominated by fear, cold, want, disease, and hunger. Science and a scheme of life based on organized knowledge are new, startlingly new in terms of race experience. This whole idea of purposed and controlled progress is even newer, and as for getting machines to do work instead of muscles, so that all men may have an abundance, it is an innovation of the moment. For the sake of vividness, let us reduce the scale of race history to terms of individual experience. Instead of a million years of race development, let us think in terms of the time it takes an individual to reach the full maturity of his powers—say 50 years. On this scale how old are civilization, organized science, the idea of progress by deliberate innovation, and this machine age? It is as if *homo sapiens* had settled down from a nomadic existence to tend flocks and till the soil only 19 days ago, as if he had grown curious about the ways of nature a little after midnight this morning, had hit upon the idea that progress does not merely happen but can be deliberately speeded up by invention and innovation about dawn and had gone about the task of making machines do his work for him only as he got up from this morning's breakfast table. Little wonder that his instincts and emotions are in confusion.

A certain anthropologist has in his collection 2 primitive stone implements, which he estimates to differ in age by half a million years. One is crude in the extreme and scarcely recognizable as a tool; the other is fashioned with considerable art. They represent the pace of unaided evolution in human affairs. As an experiment, he took modern boys with no experience in chipping stone and with only the most primitive materials, taught them in a little more than 2 hours to chip out implements superior to the best work of prehistoric man. So much for the pace of progress by deliberate scientific control. Implicit in this episode is the startling contrast between the ancient idea of static society, the mediaeval idea of progress by unaided evolution, and the modern idea of purposed and controlled progress.

## PROGRESS IS A NEW IDEA

The very idea of human progress seems to have been alien to the ancient mind. Society, it was thought, lived in repeated cycles. Some genius would appear and lift life for a time to a higher level, but as he became a legendary figure, life would lapse again to its old commonplace. Rise and fall, ebb and flow, were supposed to be inherent in human experience, but the base line was fixed and unchanging. Ancient civilization was largely backward-looking. Its poets sang of some golden age, when men were as gods. Its hopes were centered in some Messiah who might restore the glories that had been lost. The mediaeval mind, it would seem, was a little more inclined to believe in progress. Mankind might be on the upward grade, but at best it was an almost imperceptible slope, and what was gained could come only by a toilsome process of trial and error. Only modern man, armed with the tools of science, has dared to believe that the welfare of human society was in his own control.

### ABUNDANCE, TOO, IS NEW

To modern science, and its ideal of cumulative progress, we must also credit the growth among men of a psychology of abundance. To the primitive mind, with the hardships of continuous want and occasional famine branded on its memory, the notion that the earth could be made to yield an abundance of goods for all her children could seem only fantastic. Stoicism represented the highest level of virtue in an age of want. Charles A. Beard speaks of his vivid first impression of the Hindu religion, as the natural expression of the philosophy of a people with no hope in this or any other world of having a square meal. If scanty resources and production forbid the satisfaction of the most elemental of all desires—the longing for food—what greater boon could man crave than emancipation for all consciousness and desire?

The ancient world looked on slavery and aristocracy as natural institutions, or even as ordained of God. They were the inevitable consequences of meager resources. To me, it has always seemed no mere coincidence that the growth of democratic ideals and institutions has moved step by step with the growth of pure and applied science. Democracy is the political and social affirmation of the credo of progress; it rests on faith in man's capacity to produce an abundance for all. Do not make the mistake of blaming today's hunger and want on men of science and on engineers. The sad dilemma of a hungry world in which farmers burn the crops for fuel, of ragged men in the shadow of mills able to turn out 3 times as many garments and shoes as the people have ever used, of a business world as much troubled with unemployed dollars as with unemployed men, all suggests that researchers and engineers have eagerly accepted the psychology of abundance, while the world of finance and of trade is still largely dominated by the economics—or perhaps better the instincts—of scarcity.

### MAN OVERCOMES HIS LIMITATIONS

Thomas Carlyle, who had a great deal to say of heroes and hero worship once spoke of man as "the tool-using animal." However Carlyle may have meant it, this is really a great tribute to man's dignity and worth. Man, alone in all nature, overcomes his own limitations. His voice is weak and can carry only a few hundred feet; but he builds an amplifier which can be heard for 5 miles, so that he may speak to possible millions. His hearing is faint, but he makes an electric ear which can detect an airplane 10 miles away. He can count about 10 to a second, but he makes an electric eye fast enough to count 50,000 times a second. If he is accurate, he can estimate lengths to a quarter of an inch, but he captures a light wave and makes it measure to a millionth of an inch. He can see 10 or 20 miles, with the light gathered by his eye, but he makes a telescope which gathers light from galaxies 100,000 light-years distant. He holds up his hand and feels no heat from the stars, but he builds a radiometer, so delicate that in comparison with the current of an ordinary electric lamp, what it detects is equivalent to a change of 2 drops a year in the torrent of a Niagara. He, himself, is a weak, inefficient machine, but he builds on one shaft a machine to supply more work than could be done by all the slaves Lincoln freed.

Only man, in all nature, overcomes his own limitations and explores the universe about him. That is what all tools are for, to overcome the limitations of men. If ever the tables are turned and machines become masters of men, civilization will be upside down. It would be folly to assert that only good can come out of discovery and invention; but it is equal folly to blame upon researchers and inventors the hardships which come as an incidental result of their work. Back of all the details of industrial economy lies half concealed a more profound issue of social utility which scientists and engineers have never directly faced. How far is it humanly profitable to push discovery and invention? Perhaps it would be more appropriate to ask "how fast" in place of "how far." Free play to the social consequences has always been taken for granted. Individuals were bound to suffer hardships but it was assumed that society at large profited immensely. The doctrine of *laissez-faire* assumes that at least a working balance will be kept between technical and moral progress. We have seen industrial technique advance with amazing swiftness, while the moral and legal controls on which the safety of society depends were being readjusted by the fumbling process of trial and error.

### SCIENTIFIC KNOWLEDGE EXCEEDS SOCIAL INTELLIGENCE

The tools of industry are in themselves neither good nor evil. Good or evil can come only out of the uses to which they are put, and this issue, in turn, depends on the values they are employed to create. We live in a day when the ruling scale of social values has gotten badly out of step with economic facts. The triumphs of physical science and our faith in the social gains from technology have made us overconfident. Have we not built up a social structure far beyond the limits of our social intelligence? The foundations, the materials and the members of this structure which were ample in a simpler day have proved unequal to the complex stresses of a technological era. Our knowledge of men and of social institutions stands today where our knowledge of material nature stood 2 centuries back. There are signs now that we may be compelled to retrace our steps for a time to a simpler social order in order to prepare for an advance movement to new and more secure ground. Civilization may not collapse, but evolution is being speeded far beyond its normal pace. A decade may see changes in the social order suddenly realized, which are in reality the cumulative result of the work of a century. The educator and the engineer both work with an eye to the future and must take the risks of forecasting on the basis of today's facts and of yesterday's experience.

## RESPONSIBILITY OF ENGINEERS INCREASES

It is plain to all that the focus of our social interests is no longer political, as it was with the revolutionary fathers; it is economic. Their passion for political rights awakens only a hollow echo in the citizenry of today. Government based on geographical representation is showing signs of bankruptcy in an age when men's vital interests divide according to their work, rather than their place of dwelling. Our parties offer us no principles; our elections are fought around persons rather than policies. Actually the farm bloc, the manufacturers' lobby and the bonus seekers stand nearer the real issues of our public life than do the Republican and the Democratic parties. Democracy, with its trust in the collective wisdom of common men, may prove to be unequal to severe social and economic stresses. Russia and Italy have repudiated it; Japan is turning away from it; and Germany hangs precariously in the balance. The engineer has never been a major force in politics; his interests have been administrative, rather than legislative. If, in the turn of evolution, government is to be recast on functional lines of representation, our profession may find its public responsibility greatly increased.

## IMPORTANCE OF AGRICULTURE

American agriculture appears to have reached a maximum phase of development and to have entered upon a phase of decline. Until the turn of the century its history was written in terms of an unparalleled expansion of acreage and of markets. We spent millions on research to make the farmer prosperous by increasing his producing power, only to bring him face to face with a blind wall of market limitations. In a period when our manufactured output per capita was doubling and mineral production increasing two and a quarter fold, our farm production per capita fell off appreciably. Farm population has been declining at the rate of a million or more a decade, until the present crisis, and there is now a threat that the mechanization of agriculture will further speed this decline. Hope of reversing this trend seems to be in 2 possible directions. One is a great increase in the use of agricultural products and by-products as raw materials in industry; the other is a return to a self-contained farm life with little dependence on money crops. We may see the story of cotton seed repeated on a vast scale. In 1860 it was garbage, in 1870 fertilizer, in 1880 cattle feed, and in 1890 table food. Today it is an industry representing a turnover of half a billion dollars a year, 40 per cent of which goes to the farmer for what was once a waste and a nuisance. Subsistence farming appears unpromising in itself, but highly promising as an adjunct to industrial employment. The slogan of tomorrow may not be "Back to the soil;" it is more likely to be "One foot in industry and one on the land." If technological and market changes continue to make jobs in industry more and more precarious, some such combination of soil and job is about all that stands between America and a fast-growing proletariat.

While purely rural living is declining, the overcrowding of our cities may also decline. Glenn Frank reminds us that in an age of steam power, it was necessary to bring the worker to the power, but in an age of electrical power we take the power to the worker. Transport by water and rail was inflexible. Town and factory had to come to the traffic arteries. Highway transport, on the contrary, seeks out the remotest hamlets.

## MANPOWER VERSUS NATURAL RESOURCES AND MACHINES

Recent advances in technology have definitely ended our traditional shortage of manpower. This may prove to be a wholly new phase in our national history. If so, the social doctrine which has dominated our politics, our education, and our industry, based on the premises that men are scarce while space and materials are abundant, that society must cherish each individual and develop his powers to the full, that industry must adopt every expedient to "save" labor but could afford to be prodigal with ore, coal, oil, timber, water, soil, and other bounties of nature, may undergo radical revision. The incentives which urged on much of our research, have shaped the objectives of invention, and have led us to the unparalleled development of the automatic machine and process in the last 3 decades may lose much of their force. Labor surplus, due to mechanical productivity, may swing America nearer to a parallel with western Europe, with its overcrowding of population and shortage of raw materials.

For a time the curve of industrial progress appeared to be an expanding spiral. Invention, stimulated by labor shortage and drawing on a vast reserve of scientific knowledge, gave us better machines; machines lowered costs, made improved products possible and thus opened up vast new markets; increased turnover provided new capital and credit for plant expansion; capital in turn subsidized research and stimulated invention; workers were displaced by machines, then reabsorbed into new forms of production and service; tasks became more specialized and craftsmanship declined, wiping out the worker's capital in his skill; the buying power of a day's work rose and created new levels of consumption; advertisers and salesmen stood by with stimulation in hand to revive a flagging market; and the cycle was expected to repeat itself indefinitely on an ever-widening scale.

It now appears that once the magic curve is broken, it is extremely difficult to reestablish it. Possibly the curve is not a spiral after all. Some of the factors may have been transients rather than constants, and the curve may have an inherent saturation range where machine economy passes into an area of diminishing returns. Technological unemployment may prove to be not only a temporary hardship to individuals, but also a cumulative process which brings a menacing train of sociological consequences in its wake. What of the mass markets on which mass production depends? What political consequences may come from the rise of a proletariat with no stake in land or in skill or in permanent employment? What if educational and welfare agencies must make their programs and budgets fit a condition where there will be little employment for the youths under 18 and only posts of leadership for adults over 50? Society may with sound justice insist that the economic burden of labor displacements be reckoned in the costs of production. Engineers contemplating the adoption of labor-saving machinery may have to include some form of social indemnity as part of the cost burden on which a profit may be shown.

## MATERIALS INCREASE IN IMPORTANCE

The moving force in the industrial revolution of the last century and a half has been the substitution of machines for muscular labor. While this force is far from exhausted, it appears to have entered a realm of diminishing returns. Thus far the substitution of artificial materials for those more or less directly obtained from nature has been a distinctly secondary factor, but one which lately has begun to assume a commanding importance. If pushed to its limits, however, this newer force can scarcely be expected to give to industry as a whole as great a stimulus as that which comes from mechanical invention, or from steam and electrical power. It may suffice, however, to afford a considerable check on any slowing down process. In any case chemistry and metallurgy are fairly certain to assume greatly increased importance in every realm of engineering.

As a result of this growing interest in synthetic materials, the deadliest competition of today is not so much between concerns as between products. Research has been made to serve industry as a weapon of attack and of defense. Large concerns which can distribute their risks over a wide range of products and which can afford heavy expenditures for research, appear to have the best prospect of survival. The entrance of industry into the field of research marks the triumph of a new technique of invention. The philosopher Whitehead points out that what was new and peculiar to the nineteenth century was its technology. The art of writing he regards as a greater invention than the steam engine, but one which required a thousand years against a hundred for the engine.

As a matter of fact much of the earlier history of invention is one of crude practical innovation, followed—and often at long intervals—by the refinements of scientific research. Of late we have begun to reverse the order and to close the gap of time. In the modern industrial laboratory this time lag is tending to disappear entirely. Today's research becomes tomorrow's invention and the day after tomorrow's merchandise. Three decades ago industry had a veritable mountain of unused scientific information at its service. Today that margin has largely disappeared. If invention is to give industry another such impetus in the next 3 decades our research efforts must be redoubled.

## CONDITIONS MAY BECOME MORE STABLE

An era of stable rather than increasing population appears to be at hand. In the early decades of the last century our population was growing at 4 times the world rate, and in the late decades at double. The prospective scarcity of land and natural resources was heavily capitalized and vast fortunes were accumulated from this almost effortless wealth. The tempo of agriculture and industry was adjusted to rapidly expanding markets and rising wealth. Just when this growth began to slacken, the world war gave production an immense but temporary impetus, which has complicated the process of readjustment. The shortage of land and natural resources has failed to arrive; both show signs of having been heavily overcapitalized. The economic life of America is apparently becoming more nearly parallel to that of Europe where the turnover of trade rather than the unearned increment is the chief source of accumulation. The effect of this change on our national habits of philanthropy is an interesting subject for speculation. Will our educational and welfare institutions continue to enjoy private bounties on the scale of the past? Possibly not.

## PROBLEMS OF YOUTH INCREASE

To the educator the changes in the age distribution of a population which is in process of becoming stable are even more significant. If we go back to 1850 we find more than half the population of the United States under 20 years of age, and barely one person in 11 a mature adult over 50. The actuarial prospect for 1950, when the curve has flattened out, is that about a third will be under 20 and fully one-quarter over 50, in short that the ratio of mature adults to young people will have increased 4-fold in a century. In 1850, youth was abundant and at a discount, maturity was scarce and commanded a premium. Maturity is now becoming abundant and youth more scarce, with a reversal of the scale of values. The social consequences are evident on all sides. Leisure is being transferred from youth to maturity. The decade from 20 to 30 is becoming less available for adventure and experimentation. Settling down at 30 is beginning to involve risks of never making permanent connections at all. The age level of life's most severe competitions is coming down. More and more, the long and costly sequence of school, college, professional training, and apprenticeship running into the late twenties is being called into question.

If stable population and surplus manpower affect America as they have already affected Europe we may see social strata becoming more permanent, the carry-over of wealth from one generation to another assuming greater importance, a sharper cleavage forming between education for citizenship in general and that for highly intellectual pursuits, greater concern to fit young people efficiently into the economic system, more of education transferred to a continuation period running parallel to early employment, and more of an effort to create and diffuse a national culture concentrated on the growing leisure of middle and late adulthood. These changes seem to the writer to confirm the wisdom of an educational program which brings the great body of our young engineers into the normal relationships of the industrial world at the age of 22; they also emphasize the need to provide much more generously than in the past for continuation education for graduates.

## SECONDARY EDUCATION

The scope of secondary education is being greatly extended and its functions widened. Up to the present the high school has taken only an incidental part in the occupational sorting and guiding of youth. In the early future it may have to carry the major part of this responsibility. The states have been steadily advancing the age limits of compulsory school attendance. Meanwhile commerce and industry have had less and less to offer young persons seeking employment under the age of 18. The highly subdivided tasks open to these untrained beginners usually have little training and exploratory value to those in search of careers. The school has no choice but to hold all its pupils through the early stage of adolescence, and to provide them with the means of finding out their occupational interests and of measuring their capacities against the world's work. The surface of this problem has scarcely been scratched. The number of recognized vocations is said to exceed 30,000 and a majority of those in industry, at least, are so far removed from the elemental experiences of youth that a young person cannot easily visualize them or by imagination project himself into them.

The overwhelming magnitude of this task of social and occupational adjustment, involving each year an army of 2¼ million recruits to the active duties of life, has threatened to overshadow the intellectual functions of the secondary schools, and to dilute the education of young people of intellectual tastes and gifts. Schools, at times, have seemed to resemble department stores where all kinds of merchandise are considered equally important and the customer is always right. Within the last decade, however, this equalitarian movement has apparently reached its limit.

The engineering profession has much to gain from a clearer separation of the intellectual side of secondary education from its work of social adjustment. For its own recruitment it wishes students who are soundly grounded in the exact sciences, languages, history, and civics, and are accustomed to the rigors of solid intellectual work. If, as, and when the program of work now contemplated for the junior college can be consolidated with the present secondary course and completed by students of intellectual tastes and gifts at the age of 18 or 19, the engineering colleges will readily accommodate themselves to a more advanced level of entrance, and a higher degree of student selection in advance.

The certain result of greater segregation of the intellectual phase of secondary education and its gradual extension will be a greater emphasis on the exploratory and vocational phases for the vast majority together with a rising demand for continuative technical training leading up to the more practical pursuits in business and industry. There is apparently no need to increase the number of engineering colleges, but rather to make their standards more exacting and their professional aims more pronounced. As a complement to these colleges, there is unmistakable need for technical institutes and continuation schools in large numbers, with flexible levels of admission and with programs of work closely related to particular industries and occupations.

## NEW PROBLEMS FOR CAPITALISM

To return for a moment to broader social movements, we may observe that democratic capitalism, with its strong individualistic ideals, is being challenged by its own economic dilemmas from within and by rival systems in actual operation from without. Capitalism rests on the principle that what matters most to society is the use a man puts his money to after he has acquired it. It assumes that the next generation will need to consume more than the present one, and that whatever surplus of wealth exists can best be entrusted to persons who will not consume it, but use it to augment the means of production. For this service incentives are offered and rewards paid. In an era when both the population and the standard of living were rising rapidly and especially in the pioneer life of a virgin continent, this principle has been socially fruitful through its stimulus to individual initiative and thrift. We may now be at a turning point. Examples of a socially wasteful unbalance between producing and consuming power have multiplied in the post-war period in agriculture, mineral production, and manufacturing alike. Machine technology, with its seemingly limitless capacity for increasing production, has apparently accentuated this loss of equilibrium. The result has been called a dilemma of thrift. The capital and credit structure built up on producing capacity may prove to be larger than the buying power of society can sustain in the presence of forces which tend to diminish the volume of employment available. If so, capital may find it difficult to obtain new outlets and industry may be forced to distribute a larger proportion of its income in forms that directly augment consumption, that is, as wages and cash dividends. Society may deem it expedient to limit the plowing back of profits to increase plant capacity. It may also find ways to limit the mechanizing of production, rather than to have an unemployable proletariat growing on its hands.

## ENGINEERS WILL NEED SOCIAL ORIENTATION

Engineers, on whose analysis and judgment hang the risks of future investments and plant extensions, will have new social forces with which to reckon. These new forces will influence not only their more philosophic reflections, but also the arithmetic of engineering economy as well. The current social changes point inevitably to an increasing degree of social control in economic processes. The day is probably past when society will wink at socially wasteful processes of making money, if only it is invested prudently after it is made. The issue is not so much one between capitalism and socialism as between society and the individual, between a controlled economy and one based on *laissez-faire*. The engineer of a generation hence will not only have a wider range of scientific tools at his disposal, but he will almost certainly be guided by economic premises in which broader conceptions of social expediency will prevail than in the more individualistic past. He may not be an employee of the state, but he will work under a wider range of public regulation.

The engineer of tomorrow will be, as he is today, a social pragmatist, one who accepts the existing order provisionally and works within it, whether it be *laissez-faire* capitalism, Marxian communism, or Italian fascism. He will accept any system, as far as it works. This attitude is fairly inherent in his professional function and duty. If, however, the engineer of tomorrow aspires to be a molding force within the industrial system, he will need a more profound and more critical understanding of economic forces and of social values than that which sufficed for an era of rugged individualism. Social orientation bids fair to rank equally with scientific discipline as an essential basis of his training.

## Civilization Must Go On

The first duty of the engineer in a changing society is to keep civilization running. As in the theater, the show must go on. If, as some critics urge, science and machinery were abandoned and a few hundred thousand engineers were to quit for good, the whole structure of society would come down around our ears and when we pulled ourselves out of the ruins the life around us would resemble that of rural Russia under the Czars. By keeping society going, the engineer is giving evolution a chance to work.

## Guesswork Must Be Stopped

The fundamental job of the engineer is to take the guesswork out of economic life as rapidly as scientific knowledge will permit. So far he has succeeded brilliantly with process and products, and this success is opening new doors. His next job will be to take guesswork out of the use of products and resources, out of their distribution as well as their production; also to take guesswork out of the use of capital and of manpower. The functions bring the engineer into more vital contact with what are called, somewhat optimistically, the social sciences. Our knowledge of man and of social institutions stands today about where our knowledge of physics and chemistry stood 2 centuries ago. Until a better equilibrium between technical and social knowledge is built up the safety of society demands a type of leadership in industry and the technical professions which is highly sensitized on the side of social welfare and ethics. It is the business of the engineering profession to supply this leadership. We constitute the dominant professional group in the industrial world. As a profession, society has a right to expect of us a certain disinterestedness of spirit, a devotion to truth wherever it may lead, and a conscious dedication to the good of society as a whole. We are expected to have the long view and not to live merely from balance sheet to balance sheet. We have a tradition of ethical accountability. We stand for the rule of science rather than intuitive guesswork. We are not doctrinaires and revolutionaries but have our feet on the ground of fact and experience.

## The Engineer's Social Responsibility

It is a significant fact that every revolutionary movement in the world of today has tended to augment rather than narrow the engineer's sphere of social responsibility. This has been true in Russia, in Italy, in Spain, and in China. The concern of educators, in view of the present revolutionary outlook, is not so much to make our graduates more proficient in details, whether of technique or of management; it is to develop men who are able to deal in a more statesmanlike manner with the major economic and social problems of a technological era. As the writer sees it, the solution of this problem involves more than adding this or that to the curriculum or keeping the boys a year or two longer in college under the guidance of subject matter specialists. It involves a more organic conception of the whole process of recruitment, training and development within the profession—one that transcends the details of the arbitrary or accidental divisions of schooling and apprenticeship, the regulations of the licensing boards, and the rules of eligibility for the several grades of society membership.

It is encouraging to note that the joint movement now taking form among our national bodies for a scheme of professional certification looks in that direction. What is contemplated is a scheme of educational guidance that reaches down into the secondary school, bridges the college period, and covers the early years of professional activity, and which has as its objective a comprehensive appraisal of educational attainment at a mature level, as a qualifying standard for certification into the profession.

Many college men hope that this broader view, with its increased emphasis on further education after college, may so relieve the pressure on the undergraduate curriculum that a more profound grounding may be given in both the scientific and the societal groups of studies. Replacing this ground work with elementary management subjects will not solve the problem of a more adequate professional education. It may supplement it, and in a very valuable way. Courses in preparation for the management of industry are a legitimate adjunct to professional training in engineering, but if we are to remain a profession in the corporate sense and not become merely a fraternity of managers and executives, we must maintain the primacy of the sciences and of the philosophy of social institutions and relationships. We may keep our fellowship open to the administrative as well as the technical worker, but the nucleus of the profession must always be an intellectually qualified, scientifically grounded, socially intelligent body of men, bound by a strong code of ethical responsibility and devoted to an ideal of disinterested service, rather than the expediency of the next balance sheet.

# The Institute and Its Members—Our Problems and Our Responsibilities

**Many points of direct interest and prime importance to members of the Institute, individually and collectively, were discussed by President Skinner in the annual address before the summer convention. That the entire membership may benefit accordingly, the full text of the address is published herewith. ——The Editors.**

By
C. E. SKINNER
PRESIDENT A.I.E.E.

THE AMERICAN Institute of Electrical Engineers is the youngest of the 4 major national engineering organizations of the United States. Its existence closely parallels the growth of the electrical industry not only of this country, but of the world, and its printed proceedings and transactions form the most important existing records of the development of the electrical art and industry of the country. These records cover a wide field, from the announcement of outstanding inventions and scientific discoveries in the electrical art to the commercial applications of electrical devices to every possible use in industry and society. The membership of the Institute from a very small beginning in 1884 has grown to a maximum of more than 18,000. The Institute's open forum for the discussion of problems, the announcements of discoveries, the work of its standards committee, and the work of its technical committees have been potent factors in the phenomenal development of the use of electricity throughout the nation. Electrical engineers interested in every possible phase of the art have given their time, their energy, and their best efforts to the work of our Institute.

The presidential addresses of my predecessors have covered an extremely wide range of subjects. They have dealt with abstruse scientific and technical problems. They have dealt with the status of the industry at the time the address was given; they have dealt with the idealism of the engineer, with pleas for recognition of engineering as a profession, with our relations to other engineering societies, and with many other subjects. I wonder how many members of the Institute have read and studied these addresses, other than the outgoing president who is faced with the constitutional requirement that he deliver an address and who, therefore, is interested in what his predecessors have said. Some of the finest things ever said before this Institute may be found in these addresses and I despair of being able to live up to the standards set by them.

From time to time the President of the United States issues a message intended primarily to call the attention of the Congress and of the people to the condition of the nation. In like manner, perhaps I can do no better than to call the attention of the Institute's membership to the state of affairs with which we as engineers are confronted. This requires that I outline a number of things which may seem to be more or less unrelated, but all of which I believe have a bearing on the present conditions and on the future of the Institute, and some of which are of importance to all engineers.

## ACTING NATIONAL SECRETARY APPOINTED

The Institute suffered a severe loss during the year in the death of its national secretary, Mr. F. L. Hutchinson, who had served the Institute with ability, loyalty, and unflagging energy for a period of more than 28 years. The many appreciations of Mr. Hutchinson and his work that have been received indicate the high opinion in which he was held, both by Institute members and by others with whom he had come in contact. Some of these expressions have appeared in ELECTRICAL ENGINEERING. The Institute's board of directors has given earnest consideration to the selection of Mr. Hutchinson's successor. It found itself in the fortunate position of having in Mr. Henline, assistant national secretary, a man familiar with Institute affairs and with the many duties of the office of secretary. As previously announced, Mr. Henline has been appointed acting national secretary as of June 1, 1932. Mr. Henline comes to this position at a difficult time brought about by a decrease in membership and revenue arising out of our disturbed economic conditions. The situation demands the most rigid economy in the conduct of the affairs of the Institute, with very little decrease, if any, in the amount of work required to carry on Institute affairs. I bespeak the loyal support of every member of the Institute for Mr. Henline in this new and responsible position.

## BALANCING THE BUDGET

It will not be a surprise to any member of the Institute for me to say that there has been a considerable net decrease in our membership and in our income during the last year or two. Many of our members, as in every other walk of life, are unemployed and many of these are not in a position to pay their dues to the Institute. There also has been a substantial falling off in the revenue from advertising in ELECTRICAL ENGINEERING. Unfortunately, decrease in membership does not automatically decrease in proportion the necessary expense to serve the remaining membership. Consequently, the executive office, the board of directors, and the finance committee have found it necessary to make critical studies of every possible economy in order to maintain the service which every member has a right to expect from his membership. But, in spite of their best efforts, there will be a deficit at the end of the current appropriation year, and the following year may be still more difficult. Fortunately, through wise management during the past, there is sufficient reserve to meet the present deficit. However, a deficit cannot be continued indefinitely, and special studies are being made on ways and means of balancing our budget. Unlike our political friends, we cannot levy additional taxes. Consequently, budget balancing must be brought about through economies and through accessions to our membership. We must provide more service to our members, if this be possible, and at less cost.

## SECTION AND BRANCH INTEREST

During his administrative year your president has visited many Sections and Branches of the Institute. This has entailed a great amount of travel but it is hoped that the time, energy, and money have been well spent. It was most heartening to find in every Section and Branch visited an enthusiasm for the Institute and its affairs. An attempt was made to place before these far-flung units some of the problems of the Institute, particularly those in which they are vitally concerned. Special emphasis was placed on securing the cooperation and adherence of the younger members of our profession, and of the benefits which always follow their participation in Institute affairs. The arrangement of programs particularly adapted to the specific interests and needs of each local group was urged. This has been done to a very large extent in the past by these groups but no doubt even more can be done by careful planning in the future. The decentralization of Institute management and affairs by giving a large degree of autonomy to Districts, Sections, and Branches, makes it desirable that national officers of the Institute visit them from time to time. It has been an inspiration to your president to meet with the outstanding groups of engineers that compose these units scattered throughout the United States, Canada, and Mexico. I found no greater enthusiasm for, or loyalty to, the Institute than in the 2 Sections visited in Canada and the one in Mexico.

The committee on education has given loyal service to the Institute during the year and has been doing what it can to aid at this time when so many of the graduates of the electrical engineering departments of colleges and universities find it difficult, if not impossible, to secure employment. A very few years ago graduates could select any one of several positions offered. Today there are but few positions available, and many graduates of a few years ago are now hunting for jobs. In a recent radio address a prominent speaker congratulated the graduates of today on facing a time of adversity which brings out the very best that there is in men and which will be of inestimable benefit to them in their future careers. There are some definite records showing that graduates in times such as these have gone further, on the whole, than those of better times when positions were easy to secure and easy to hold. This should give some comfort, encouragement, and renewed determination to the engineering graduates of 1931 and 1932. In this connection I would like to second the recommendation made by a prominent educator, that recent graduates who are unable to find positions carry their education further, either by specialization in their chosen line or in business courses, if such additional schooling can be arranged. Such training will be of value in whatever field the engineer may find his life's work.

## THE ENGINEER IN BUSINESS

During recent years undue emphasis perhaps has been placed on the desirability of a business career for engineers. This undoubtedly has resulted from observation of the outstanding successes of many high executives who are engineering graduates and who have had engineering experience. In spite of what will be said later in regard to the engineer taking his place in the councils of his community, the state, and the nation, which more or less presupposes training on broad cultural and business lines as well as in engineering, it is hoped that too much emphasis will not be placed by educators and others on a business career for engineers. The future undoubtedly will require for research, design, and construction, many highly technically trained engineers, who will find enduring satisfaction in work of this kind. Certainly some business training should be no handicap to the engineer, regardless of what his life work may be. In the future as in the past, men of engineering training undoubtedly will find high places in business administration, but also there will be outstanding careers for men who devote their lives to the more or less strictly technical side of engineering.

I would like to record here a specific recommendation which I have made to the chairman of the committee on education. This suggestion is that outstanding papers by students be repeated at other institutions when 2 or more Branches are within relatively easy travel distance of each other. Among the more than 1,000 talks and papers given by students during the year there are many that justify delivery before wider spread audiences and this would be accomplished by the adoption of the suggested plan. Such a plan should be a stimulus to authors and give those who are so fortunate as to be selected an invaluable experience, not only in writing and delivering papers, but also in meeting the criticisms and suggestions which undoubtedly would come from the delivery of such papers to groups in rival institutions.

## PUBLICATION POLICY

Two years ago the publication committee of the Institute concluded a searching inquiry into the question of our publications. As a result of this inquiry and recommendations coming out of it a very considerably modified policy was adopted, particularly with regard to our monthly publication now called ELECTRICAL ENGINEERING, now 18 months old in its new form. In my visits to various parts of the country I have heard a great deal of praise for this publication and extremely few criticisms. These criticisms come mainly from those who believe that ELECTRICAL ENGINEERING should confine itself strictly to technical matters and not include any commercial or so-called popular material. It should be remembered, however, that the membership of the Institute embraces individuals interested in every possible phase of the electrical art, from the most abstruse mathematical conceptions to the most common applications of equipment and devices in our daily life. Catering to this widely spread interest is no easy matter, but I feel personally that the editors of ELECTRICAL ENGINEERING in cooperation with the publication committee have attained an enviable success with our national magazine, and have constantly improved it. It may be of interest to our members to know that during the past year we have printed more than 1,000 pages of text matter in ELECTRICAL ENGINEERING, or, in our monthly edition of 23,000 copies, a total of more than 24,000,000 pages for the year. In our TRANSACTIONS we printed more than 1,700 pages of text matter in an edition of 5,000 copies, or a total of approximately 9,000,000 printed pages. This compares very favorably with the amount of literature put out by the other national engineering societies. Also our expenditure for publications per member and per dollar received from dues is very well in line with the equivalent expenditure by the other societies.

## HISTORY SHOULD BE WRITTEN NOW

At the 1932 winter convention in New York, I suggested that possibly the time had come to consider the writing of a comprehensive history of the Institute and of electrical engineering, particularly with regard to the formative years of the industry. This suggestion has evoked considerable interest and, as a result of several communications and suggestions, the board of directors authorized the appointment of a special committee to consider this subject and to report on the possibility and feasibility of such an undertaking. This committee consists of Dr. W. J. Foster, Dr. F. J. Sprague, and Dr. C. F. Scott (chairman). This committee has given some study to the question, but as yet has not presented a final report. A preliminary statement now in the hands of your president brings out several important suggestions, one or two of which I am quite sure the committee would be glad to have me emphasize here. Naturally, the task of writing a really comprehensive history is a large one and undoubtedly would result in the equivalent of an encyclopedia on the subject. The committee believes that one of the things most desirable to accomplish at the present time is to procure as much source material as possible from the pioneers who were a part of the great industrial drama of electricity. It is suggested that since the semi-centennial of the founding of the Institute occurs in 1934 it would be fitting and appropriate to have historical papers on the subject available by that time. I would like to urge those who are in position to do so to undertake the writing of such papers dealing with the specific phase of the subject with which each person is most familiar. Even a few pages of facts would be of value to our historians. The TRANSACTIONS of the Institute and the files of the electrical trade press contain much of the technical material that will be required in the construction of the history which I have in mind. However, these papers contain but little of the human-interest stories which would go so far to make such a history really readable. They give little or nothing of the aims and aspirations, the trials and reverses, or the personalities and rivalries incident to these early struggles. Very few of us are fitted to write a story in finished form as we would like to see it appear, but there are few who could not put down in simple language that part of the story with which each is familiar and which, if filed with the Institute, would become of inestimable value in later years for the "Prescott" or "Motley" who becomes the eventual historian of the rise of the electrical industry. I would like, therefore, to urge the writing of as many biographies and autobiographies as possible even though these may never appear individually in print. Future generations would indeed be greatly enriched by having such documents in the archives of the A.I.E.E. as source material. Outstanding examples of such documents are the biographies of Dr. John A. Brashear and Mr. John Sweet, and the autobiography of Mr. B. G. Lamme.

## AMERICAN ENGINEERING COUNCIL

Several previous presidential addresses have stressed the responsibility of the engineer as a citizen and the desirability of engineers bringing to bear on national and civic affairs the training and point of view that have made engineers so successful in their own fields in the past. Certainly at no time in our history has clear thinking, honest fact finding, correct deductions from these facts, and unbiased recommendations based thereon been so necessary as at present. Our amazing material progress during the last 50 years is due in large measure to the work of engineers. Whatever the causes that have resulted in the present conditions, there seems to be a wide-spread feeling that relief must come through the application of the engineering method. The American Engineering Council, of which the American Institute of Electrical Engineers is one of the constituent members, for many years has been endeavoring to help and guide in those larger problems which are beyond the limitation of any one national or local engineering society. Council has been endeavoring to give unbiased, constructive advice in national affairs which directly affect all engineers.

Outstanding studies by Council that have been completed, include "Waste in Industry," "The Relation of Safety to Production," and other studies. The most important study yet undertaken is now under consideration, namely, "The Balancing of Production, Consumption, and Distribution in Industry." It is expected that Council will divide this project into several units and, with the best talent that can be obtained in engineering circles cooperating with other interested agencies, undertake to arrive at definite conclusions in regard to some of the questions which have so disturbed the country, and even the world during these depression years. The Institute through its adherence to the American Engineering Council and to the Engineering Foundation is a party to and a supporter of this very great and worthy enterprise. It is hoped that the fact-finding method of the engineer, working with others interested, will result in the accumulation of sufficient real data on which economists, business men, and government agencies may base future action to prevent unduly wide fluctuations in the business cycles of the years to come.

The American Engineering Council has been fostering the organization of state councils along the same general lines as the organization of the American Engineering Council with the object in view of having such councils take part in state and local affairs in a manner similar to that of the American Engineering Council in national affairs. Such councils already have been organized in several states and your president, in his visits to various parts of the country, has been strongly urging the organization of these state councils. It is especially desirable at this time that such local councils study and endeavor to guide such state and municipal legislation as affects engineers and engineering, particularly as the cost of government in so many lines has been mounting by leaps and bounds with many projects proposed that are either unsound or unnecessary. Certainly no one is more competent to advise on engineering matters than are engineers themselves, and their advice will have weight if and when they are organized and when they advance arguments and opinions from the unbiased result of fact finding and not colored by self-interest. It is believed that engineers as a body are perhaps in a better position through their training and experience to divorce themselves from such self-interest than any other class of citizens.

## ADVICE DURING FINANCING OF PROJECTS

During the boom years preceding the crash of 1929, many securities were sold to the public covering projects some of which had been condemned as unsound by prominent and reputable engineers. There were perhaps more of these projects in which such engineering advice was neither asked nor desired. Perhaps it may be admitted that some projects passed upon by engineers have proved to be unsound, but it is quite certain that sound engineering advice even during the boom days, if arranged for and followed, would have saved our citizens many millions of dollars now tied up in more or less worthless paper. The American Institute of Consulting Engineers for several years has been endeavoring to have investment bankers of the country secure advice from reputable independent engineers on projects being financed. This seems particularly desirable in connection with those projects for construction work in foreign countries financed by bond issues floated in this country. We are told that this practise has been generally followed by British financiers in making foreign loans; not only do they secure preliminary surveys and advice, but they usually have a definite follow-up after the loan is made to insure that the money so loaned is efficiently used for the project for which the loan was made and that the project is properly administered during the life of the loan. The wisdom of this recommendation seems so obvious that its desirability should not be questioned. Its omission has been disastrous to many who purchased such securities. While electrical engineers perhaps are less involved in matters of this kind than some others, yet undoubtedly electrical engineers have been and will be called upon for such surveys and it should be increasingly the practise of every investor to make sure that engineering and construction projects be so reported on and approved by independent engineers of the highest reputation for honesty and good judgment, before such investments are made.

There is a more or less constantly increasing number of states passing laws requiring the registration of engineers who practise within the commonwealth. This registration usually is required of engineers who undertake work in which the public health or safety in any way is involved. In my visits to various Sections, I have urged, and I again wish to emphasize, the importance of state engineering councils seeing to it that, so far as possible, proposed legislation for the registration of engineers be uniform, reasonable, and satisfactory to all parties at interest. This can be done only in cooperation with other national and state agencies when such legislation is under consideration.

## GOVERNMENTAL PROBLEMS

The past few years have seen an enormous increase in the cost of government—national, state, and municipal. A very large proportion of the taxes collected for this expenditure is levied on organizations, facilities, and products with which engineers have had much to do. As these tax burdens become more and more onerous, engineers, along with all other citizens, have an increasing responsibility in endeavoring to see that taxes are reasonable and that monies so collected are efficiently spent. For many years engineers have been endeavoring to secure in the national government the consolidation of public works of various kinds now carried on by many unrelated and uncoordinated groups. The American Engineering Council has urged consistently the legislation necessary to accomplish this purpose. As Secretary of Commerce, Mr. Hoover strongly advocated the consolidation of such work under the direction of a highly qualified executive. As President he has repeated this recommendation in a message to the Congress, and there is some hope that legislation soon will be enacted that will attain at least a part of the objectives so long advocated by engineers. The lack of such coordination undoubtedly has cost us much money, and has had its influence on the increased taxes which have been levied from time to time. Also, we are only too familiar with waste and extravagance, and even more serious problems involved in the handling of public works. I believe that organized engineers can do much to better conditions in those places where there is inefficiency, lack of coordination, and wasteful extravagance. They should join also with their fellow citizens in demanding honest administration under efficient leadership in all the affairs of those who govern us, and particularly those who are responsible for expenditures in which engineering has a part.

I have wandered, perhaps, rather far afield from the special interests of the American Institute of Electrical Engineers and its members, but I wish to emphasize as strongly as I can the point that electrical engineers—indeed all engineers—have in addition to the loyalty which is due their national organizations: a responsibility to their fellows, to the state, and to the nation. These responsibilities can be discharged only by engineers taking an intelligent and active part in all those affairs which affect them and their fellow citizens. The electrical industry in the past has had an outstanding part in the prosperity of this nation, giving its citizens facilities, comforts, and conveniences, such as never before had been known in any time or in any land.

In spite of the many difficulties and inefficiencies which surround us, we live in the finest country in the world. I am optimistic that we will be able to follow the example set us by our fathers and go forward to better government, higher ideals, better living conditions, and equal opportunities for all.

---

# Educational Aspects of Engineering and Management

By R. E. DOHERTY
MEMBER, A.I.E.E.

Yale University
New Haven, Conn.

**In view of clear trends of experience—of the movement of engineers into management—shall we conclude that technical engineering has proved to be an effective and sufficient training at college for those who may later enter the field of management? Or, shall we consider it necessary to modify radically all engineering curricula in order to prepare men *primarily* for management? Or, again, and from the same experience, shall we plan separately for each? And, having answered this, what should the plan be?**

THE GENERAL SUBJECT of engineering education has had searching and extensive study during the past fifteen years. Thus, there now exists a prodigious mass of material in all stages from raw data to carefully thought out conclusions and recommendations. As one attempts, by casual study, to form a rational opinion regarding educational policy as it relates to engineering and management, one is likely to become lost. At least this was the writer's experience.

A careful study therefore was undertaken of the new facts, their historical setting, and of the basic views underlying prevalent thought. From the perspective thus arrived at, a future educational policy, which seems appropriate to the writer, was framed. Since there are doubtless many others interested in this problem who have experienced a similar confusion in the face of conflicting opinion and the great tonnage of undigested data, it seems in order to present this study. There is one phase of the general problem which does not seem to have been considered seriously in previous studies, and that is the practicability of an effective training for general management in non-technical industry by other subject matter than technical engineering. This possibility is recognized in the present study.

## FACTS

The first step in the study was to ferret out and compare the major, relevant facts from the various surveys. The summary facts thus indicated, which apply certainly to mechanical, very probably to elec-

---

Essential substance of a paper (No. 32-75) presented at the A.I.E.E. summer convention, Cleveland, Ohio, June 20-24, 1932.

trical, and possibly to most other engineering graduates, are as follows:

1. About one-half of all such engineering graduates by the time they have reached 40 years of age, have gone into industrial work primarily executive in character. These include two approximately equal groups:
   a. Those whose duties have *required* a substantial *technical engineering knowledge.*
   b. Those whose duties have not required such knowledge.
2. Only about one-quarter of electrical and mechanical engineering graduates have remained past 40 years of age in purely technical engineering work, involving practically no executive responsibility.
3. The rest, or roughly one-quarter, have gone ultimately into work such as teaching, selling, and consulting, all of which involve dealing with people.
4. Those who have gone into work involving executive responsibility (group 1) have, on the whole, received greater financial reward than those (group 2) whose work has not involved such responsibility.
5. Those in *general* management (group 1b) whose duties have been entirely administrative and practically non-technical have, on the whole, received much greater financial reward than any other group.

Three extremely important facts of general knowledge might be added:

6. Practically all college graduates, whether engineers or not, that have become successful in management have learned all they have known about it in practise. Formal college training in management, in the general sense, has existed only during recent years, and in only a few institutions. But it is steadily increasing.
7. Practically all engineering graduates, whether they have gone into some form of management or not, have encountered those human relations which are inevitable in the cooperative enterprises in which engineers engage.
8. The great technological progress of the last half-century has been based, first, upon the extension of scientific knowledge by scientists; second, upon the careful and rational application of this knowledge to the solution of practical problems by engineers; and, third, upon the organization by those in management of capital, physical facilities, and men for production and distribution.

## IN RETROSPECT

Industrial management and engineering are twin brothers; they have developed together. During this development, both industrial management and engineering naturally experienced a correspondingly extensive metamorphosis. The range in responsibility and in requisite talent, ability, and knowledge was multiplied a thousand fold. This extension of industry was upward, fan-like. The small factories and machine shops continued, but there was also tremendous growth both in size of organizations and in range of products in the expanding industries. This two-way growth necessarily demanded not only a commensurate increase in level of ability to handle the more complex management problems, but also a corresponding increase in technical knowledge and skill. In this expanding industry, including even those branches of non-technical character, the problems of both management and engineering called for less and less guesswork, and more and more rational treatment.

Under these conditions of growth there happened the thing which might have been expected. Practically all the conditions were favorable for the engineer to be called to management positions. He was geographically on the job; his distinguishing character stics—a scientific attitude of mind and method of approach—were among the foremost requisites; and, moreover, he was vitally interested because he not only understood the processes and the products, they were his creations! Hence by normal growth and evolution many engineers have come into administrative positions.

What has been the past relation of education to management? To what extent has engineering training been appropriate and adequate for management; to what extent, essential? Formal college training in industrial management is of recent origin, and hence has had very little, if any, influence in determining the present personnel in management. However, the character of engineering education undoubtedly has influenced it; how much, relative to the influence of other existing forms of education, is not altogether clear. How appropriate engineering training has been for those management positions for which technical knowledge *per se* has not been a requisite, either directly or as a stepping stone, is largely a matter of opinion. Only this is certain: to the extent to which a quantitative method and a scientific attitude and approach are requisite or desirable in management, engineering training is highly appropriate.

In relatively recent years there has been a growing recognition, in the educational policy of engineering colleges, of the all-pervading fact that the majority of engineering graduates have gravitated ultimately to some form of management. This recognition largely has taken the form of adding appropriate electives to the regular engineering curriculum, and in setting up new courses under such headings as industrial engineering, engineering administration, etc., in which the essential core has been engineering.

But there also has been a rapidly growing philosophy which would not recognize the essentiality of *technical engineering* subject matter in college preparation for general industrial management. It holds that a scientific attitude and rational method of analysis, which are recognized both as essential and as characteristic of engineers who have succeeded in management, can be developed on some subject matter other than engineering. This general idea has not yet taken full-fledged practical form, to the writer's knowledge, unless some of the business administration courses are so regarded; but it is being reflected in the gradual deletion of technical engineering matter from such courses as mentioned above, and the substitution of general management studies. So the presumably more direct and certainly less exacting college approach to management gradually is being set up.

The financial reward for technical leadership has been less than that for general managerial leadership. According to the statistics, the man who has been able to "run" things—to coordinate human activities effectively and to judge soundly—toward definite objectives has been valued more highly by leading executives than the man whose natural talents have been in a technical vein. Moreover, according to the facts, even those who could manage men and things in technical activity have received less financial reward than those in "general" management, in which technical engineering knowledge *per se* is either not essential or altogether secondary. Going still further, those who have remained in purely technical work with no executive responsibility have been the most poorly paid. On the face of it, then, it would appear that in some fundamental way, mere association with technical matters relegates one to a lower stratum in financial reward.

However, that it has been so in the past should not be accepted as the establishment of an eternal fact. Random play of tremendous forces out of equilibrium have been the order of the day and we must be wary in drawing conclusions from experience of such a character. Nevertheless the clear implication is that something is wrong; technical engineering leadership has played too important a part in the past and obviously will be too much needed in the future to be overlooked now and smothered into insignificance under our intense enthusiasm for industrial management, which it largely created. It is not a question of merely giving such leadership its due; simply we should be stupid trustees, indeed, to the next generation if we created a problem for it by letting the present trend slip ahead unabated. Our first problem in this connection is to try to understand the past better. It is complex enough, but a thoughtful review does indicate, here and there, a rational thread running through it all.

Supply and demand, as it relates to the present subject, seems to be one such thread. In the mad rush ahead there has been a greater relative scarcity of managers, for whom no formal college training facilities had existed, than for technical leaders, for whom such facilities had been abundant. But scarcity for that reason, it should be observed, was only an accident; it was not a scarcity of natural management-talent.

If much of the best brains turned to management and, moreover, if there yet continued to be a scarcity of management ability, it is not at all surprising that this should be reflected in financial reward. By and large, if those who entered management could do the technical work the others were doing and were also capable of managing, were they not more valuable?

Engineers who have remained in purely technical work—about one-quarter of all engineering graduates—have been poorly paid relative to all others. This probably can be justified. They have learned how to make certain routine calculations, drawings, or tests, or to operate some machinery, and they do these things day after day in a routine and satisfactory manner. Their work is important—indeed essential—but a four-year college education is hardly a necessary prerequisite. Those who have remained in such positions, for the most part, have not possessed the requisite qualities of a successful engineer; and, doing the work merely of a trained technician, they have been paid accordingly.

However, there is one element in this financial reward matter which does not fit in so well. *Creative*, technical engineering *leadership* has not been rewarded appropriately. There are two sides of technical leadership. One is technical management, which administers the day-to-day technical processes of operation, design, or calculation. The other is *creative*, professional leadership in technical matters. In this leadership is that small group of 10 per cent or so of scientists and engineers who are identified by *creative achievement*. They are the ones who can see through the technical mists which blind most of us; who thus provide the radically new concepts and methods, whether they be new forms of machines or structures, new ways of building these, or new principles and methods of predicting performance. These things are absolutely indispensable to technological progress in the same sense that the products of creative, professional leadership in management are absolutely indispensable. One whose head is a fountain of *creative* ideas is thus a technical leader, even if he cannot himself do much toward putting them into practical or material form. If he can, he is simply that much more valuable as a leader. The one quality rounds out and supplements the other. Either may predominate in equally valuable men—valuable as measured in terms of achieved results. Both functions are professional in character and are complementary in relation to each other; and therefore should be regarded more nearly on the same basis so far as reward is concerned than they have been.

However, there is a very definite, favorable trend in policy about these matters in some of the large industries, even if this is not reflected in the surveys; so there are indications that creative, technical engineering leadership is beginning to approach its proper estate.

## LOOKING TO THE FUTURE

When we orient ourselves in the direction of present trends and follow out those few clearly discernible lines from the past, they seem to lead to certain fairly definite indications. The foremost of these is that the future will have no less need than the past for leadership both in the scientific and technical fields of engineering and in management. On the contrary, the need will probably be greater; everything is getting more complex; each year it is becoming more difficult to see from one end to the other of this growing, technical-economic-social crazy-quilt with such thousands of complicated, overlapping and changing patterns. Minds trained *for leadership* will be all the more essential. Inventors must more and more have advanced scientific knowledge; the cream of invention has already been skimmed from the more obvious aspects of science, and therefore inventions will unquestionably become, in increasing measure, the product of scientists and engineers. The real leaders in technical engineering must also be more thoroughly trained in the basic sciences and in the rational applications of scientific principles to practical problems. Moreover they must learn to deal more effectively with other people, for it is a part of their job. And leadership in industrial management must likewise become broader in its outlook, more scientific in its knowledge, and more rational in its approach to general management problems. In a word, all professional leadership—not excluding law, banking, the clergy, and the rest—must broaden its outlook, perennially develop its scientific base, and improve its art; else, in the inexorable advance of complexity, the leaders will become even less able than they are now to see across the boundaries. We all have taken hold of the technological bull's tail, and it is too late to let go; instead we've got to plan pretty quickly how to guide this brainless, powerful brute toward a rational objective, or he will presently distribute us prostrate over the terrain.

Another indication is that the same forces which have moved engineers into management will continue to do so, in a somewhat modified form, in the future. In the first place it will probably be modified by the influx of a new group which has not existed during the past growth of industry, namely, college graduates who have had formal training in the fundamentals of general management, but who have had little, if any, technical engineering training. In the second place, there will be the graduates of those existing courses which, although still designated—in most cases properly so—as "engineering" are intended primarily as fundamental preparation for industrial management. Such management courses should retain those elements which engender the method and attitude that have been characteristic of engineers, and which presumably have been the keynote of their success in management.

The tremendously wide range in types of industry surely affords openings in management for men of all degrees of technical training. Even in the most technical industries there are many administrative positions which require only a very limited technical knowledge; and the higher one looks in the organization, the more this seems to be so. Hence, if the colleges do a good job, it seems practically certain that within another generation graduates of engineering-management and other less technical courses will figure heavily in industrial management.

However, there is one point to be kept in mind. There should be at least some individuals in the high levels of general management who have an understanding and appreciation of technical matters and a sympathetic interest in research. These can come most effectively from former technical leaders. The half-informed business executive who disparagingly avers that he can get all the engineers he needs at $40 per week, or who naively believes that creative processes can be put on a mass production basis, is a misfit in modern industry.

What is the future for technical engineering graduates? Are they doomed? Not at all. On the contrary, their estate should become as attractive as any, if industry and the colleges adopt wise policies. Two important phases of management indubitably will be reserved almost exclusively for them, and all other fields will be open to them just as they have been in the past, except that the competition will be more keen. One reserved field is technical administration, which has always served as a stepping stone to higher levels. The other, and altogether foremost, is the creative, professional guidance and administration of technical and scientific progress. In this latter field also will be those technical and scientific leaders who may not be capable of management in its strict sense. These fields afford broad and extensive professional opportunities for technical engineering graduates; and adding to these fields the opportunity as in the past, to enter any other phase of management, the future possibilities for such graduates can be highly promising.

## FUTURE POLICY

Educational policy cannot logically be separated from industrial policy; there are too many respects in which they are tied together. Most engineering graduates enter industry of one form or another, hence engineering colleges always have taken into account the requirements of the industrial job. When industry wanted graduates who were "practical," the colleges built workshops and tried to make their courses practical; when it changed its mind and insisted rather upon more "fundamentals," they gradually swung in this direction; and when it put large numbers of engineers into management, they worked out courses which would be preparatory to management. Thus any rational educational policy must give appropriate recognition to this interlocking of interests between the industries and colleges.

Moreover, an educational policy surely would be inadequate that did not recognize the often expressed hope that the engineer might sooner or later take an active interest in those unsolved, complex social and economic problems which his technology has largely created. What should that recognition be? Sociology, industrial history, and more economics? Undoubtedly this would be valuable to the engineer if he later took such an active interest, but those engineering graduates who have gone into business, banking, management, etc., have not done so because they have studied such subjects in college; forces of circumstance and, above all, a special type of qualification have combined to move them there. In all probability if the engineer ever takes an effective hand in the solution of such social problems, it will not be because he studied subjects relating to them as a major part of his curriculum; for if he did, he wouldn't be an engineer, by definition.

There is an unfortunate and illogical tendency to classify as engineering almost everything that is done thoughtfully. The two most distinguishing characteristics of engineers are straight thinking and an unqualified respect for facts. There seems to be a growing tendency in engineering circles to assume that these characteristics are inherently present in engineers and inherently absent in others; that other professional activities—general management, business, finance, etc.—become engineering when they are thoughtfully done; and that engineering training is the only sound educational basis for such activities. However, a statement probably much nearer the truth is that, although the definite laws and data of engineering are favorable to the development of such characteristics, nevertheless engineers develop these to a high degree simply because otherwise they cannot endure professionally. The necessity of developing fully such characteristics has been less pressing in other professions. Perhaps the latter may learn something from engineering. If so, good. But let us keep engineering as engineering, and not try to stretch its curriculum over the whole domain.

Some general observations should be stated now regarding college educational process, as the writer views it. This is venturesome, because he is not qualified as either a professional educationist or a psychologist, and therefore may violate technical terminology and perhaps more; but it seems necessary, for the purpose in hand, to state in a layman's terms the more or less distinct phases of educational process as they appear to him. There are thus five largely parallel phases, as follows:

1. The first relates to the process of acquiring factual and definitive knowledge. One learns, for instance, the factors in the "flexure" formula in mechanics; the *definition* of "marginal utility;" that Disraeli was an English statesman. It is the process of building up one's mental encyclopedia. It is essentially a memory matter.

2. The second has to do with that type of reasoning in which the student is *led*, step by step, through logical processes either by a teacher or by a text-book. His part in this particular phase of his journey through the educational forest is not to move precariously along a trail which is only blazed; instead he rides on an educational sight-seeing bus over a modern, concrete highway of which even the curves and grades are reduced to a minimum. His only responsibility is to take due note of the scenery, and of the announcer's comments as he rides along. For instance, he may thus be escorted through the *logical development* of the "flexure" formula; of the *theory* of "marginal utility," or of the vector representation of alternating currents. This process is one of civilization's necessary short-cuts to the frontier of new things. In the process one's mental muscles are developed somewhat, but not under their own power.

3. The third phase is the process of acquiring skill in manipulation. For example, one develops skill in algebraic transformations; in numerical calculation from formulas by the slide rule; in operating a machine; or in carrying out an experiment. It is a discipline in procedure.

4. The fourth phase relates to that type of reasoning in which the student himself takes the initiative. *He* establishes the trail. The objective at first may be defined for him, and perhaps its general direction and a few landmarks may be indicated; but he presses through alone. In clearing away the undergrowth, in fording or swimming the technical streams which cross his path, in retracing his steps for a new start when he encounters an impasse, he not only exercises his mental muscles in worthy activity and stretches them to the elastic limit, but also develops his sense of direction and his power of discerning helpful landmarks. Each successive trail thus established *by him* increases his pioneering powers; and presently he will be able, if it is in him, to blaze his own trail through new areas to new objectives.

5. The fifth has to do with the establishment of a natural continuity between the development of the individual at college and after college. The branches of a truly educational program will neither terminate in dead ends here and there during the college course, nor be chopped off at graduation. Instead, they will feed *primary educational stems* which will continue and expand beyond graduation as long as the individual is on the ascending slope of his professional career. However, the extension of such stems after graduation is extremely difficult unless the student has already begun to extend them under his own steam before graduation. He must develop under guidance both the *desire* and *power* to extend them. This means a competent leader as a teacher, a curriculum well balanced for the purpose, and a plan obvious to the student.

Of the foregoing five phases, probably the first three are essential in the preparation for engineering work of any character; they are sufficient for *routine* technical activity, but the last two, in addition, are absolutely essential to progress toward any highly *professional* goal. If they are omitted at college, as they largely are, the graduate is obliged to provide them somehow after graduation, or else not reach the goal. To correct this situation—to provide phases 4 and 5—is, in the writer's opinion, the foremost problem confronting pre-professional education.

Turning more specifically to the engineering management aspects of educational policy, those students who would come within the scope of our subject can be classified under four divisions according to natural qualifications and appropriate education. It still may be very difficult practically to identify these groups completely, but they exist nevertheless, and every effort should be made to learn better to identify them. They are as follows:

**Sub-Professional Group**—Those primarily qualified by nature to carry out assigned tasks, either in technical work or in routine supervision. These comprise at least one-half of all college students that come under the scope of our subject. They comprise not only those whose intellectual qualifications limit them to such activities, but also those who don't want to do anything else. There are people of high intellectual ability who shrink from responsibility of any kind, or who are misfits, or who are plain lazy. They all seem to share a common level. The educational program for this group, excepting the misfits and the lazy ones, should be that of the technical institute which recognizes primarily the first three phases.

**Professional General Management Group**—Those who have outstanding natural powers of leadership and understanding, but relatively little technical leaning. This group may be expected to fill a portion of those positions of industrial and business administration—general management—which do not require technical knowledge.

Just what their educational program should be is a question largely outside the writer's knowledge. However, they must be well educated men of reasonable culture. Hence it is safe to say that there should be at least two, possibly three, stems: a cultural, a social, and economic, and possibly a slim technical one. The experiment of training men directly for general management is an interesting one, and should be encouraged. One great danger to be guarded against, of course, is the idea in students' minds that such a course provides the "royal road" to general manager or president.

**Professional Engineering Group**—Those who have outstanding natural talents along technical lines, some of whom have, in addition, the natural qualities of human leadership. From this group we should expect the future technical leaders; to some degree, leaders in general management and possibly also a few who would become actively interested in the larger social and economic problems.

Their program at college should have three stems—one main and two auxiliary: technical, cultural, and social and economic. The first and main stem should be a rigorous and thorough technical discipline. It should recognize all five phases; it should lay more emphasis upon the interpretation of fundamental physical laws and their application to the solution of illustrative problems than upon the memorization and use of standard formulas in connection with type-form cases; it should continually consolidate the gains achieved in all branches by feeding them into the main educational stem. For instance, in the junior and senior years it should make use of the results achieved in mathematics, physics, and mechanics, not in separate problems in as many classifications, but in engineering problems involving all. Past achievement would thus be unified with respect to the main purpose.

The cultural stem necessarily must be slim. But it can and should be vital. Perhaps the most that can be expected in the brief time available is to emphasize the technique of speech and writing (phase 3) and its fundamental purpose—namely, to express an idea clearly—and to *engender the habit and desire* of purposeful reading of historical, philosophical, and other cultural literature (phase 5).

While the social and economic stem is like the cultural in two respects, nevertheless it is of relatively greater importance. It is like the latter both in that it is auxiliary in character, and that the general educational purpose is gradually to establish the habit and desire of reading and thinking in a given field. In this case, however, it is about such practically important matters as industrial history, human relations in industry, sociology and economics of engineering industry and business. Taking courses in such subjects and letting it go at that is not enough; it must all be purposeful.

**Professional Engineering-Management Group**—Those all-round, capable men who have a definite technical leaning and also the natural qualities of leadership. This group, after graduation, may be expected to pass along the industrial, three-stage separator in which the first stage comprises the lower and moderate levels of technical activity; the second, technical management; and the third general management. Each stage will take its toll of men. And again, one would hope that some of these would ultimately become interested in general social and economic problems.

Their college program should have the same three stems as the *professional engineering group*, but there should be a fundamental shift in emphasis in two of them. This group should develop and retain the engineer's attitude and his respect for quantitative facts and measurements, because that attitude and respect will always be highly useful, and because technical engineering practise presumably will constitute the entrée to management responsibilities. However, the latter, being the main objective, should be given a corresponding weight in the program. Thus the social and economic stem should receive the same relative weight as the technical stem for the professional engineering group. For the present group, the technical stem should lay relatively greater emphasis on the first two phases; the social and economic should emphasize the last two phases. Analytical and pioneering powers should be exercised heavily on the subject matter of the social and economic stem, so that this will have a vital growth after graduation. For illustration, take human relations in industry. Can you teach in undergraduate courses the professional technique of personnel management, or the art of getting along with associates? It would seem to be quite hopeless. But you can introduce the student to fundamentals, and exercise his analytical powers on actual personnel problems—all with the idea of developing a purposeful and enduring interest.

The cultural stem should presumably be the same as that for the *engineering group*.

## SUMMARY

During the development of industry, engineering and industrial management have evolved together. Certain phases of management, as the writer views it, have actually been a part of engineering; others have not. The direct administration of technical engineering activities *is* engineering in the same sense that the administration of personnel and procedure in a legal matter is law. However, we should not become confused; the further movement of engineers from such technical management to general management has not made the latter become engineering, any more than the movement of numerous lawyers also into general management has made it become law. It is still general management. Engineering and management are thus closely related, but all management is not engineering.

Looking to the past, the facts are that more than a quarter of engineering graduates have gone into general management; a quarter have remained in technical management, which is engineering; a quarter, in purely technical activity; and the rest in sales, consulting, teaching, etc. Those who have gone into general management have received the greatest financial reward; those who have remained in purely technical activity, the least.

Looking to the future, it appears that technical engineering graduates will have the same opportunity as in the past for movement into such positions, excepting that they will be in competition with graduates of courses designed as fundamental preparation for executive positions. There is a very real danger that both the prospect of a greater financial reward and the less exacting nature of these presumably more direct courses in preparation for management will cause many who are naturally qualified for such work and who will be needed for technical leadership in the next generation to turn from technical engineering courses. The problem of financial reward is one which the college cannot solve; industry must do it, not alone to give creative technical leadership its due, but, in industry's own interest, to prevent the source of technological progress from drying up.

For the purpose of defining educational policy, the students who fall within the scope of our subject can be broken down into four divisions: a *sub-professional* group, and three professional groups, namely, *engineering*, *engineering-management*, and *general management*. The educational program for the sub-professional group should be that of the technical institute. It should recognize primarily the first three phases of educational process—the acquisition of factual and definitive knowledge; the development of technique in manipulation and procedure; and the understanding of basic theory. The programs for the professional groups should recognize all five phases, and should emphasize particularly the last two—*viz.*, the exercise of analytical and pioneering powers; and the development of *primary educational stems*, and of the power and desire to extend and expand them after graduation. It is around these stems that the results of purposeful study and experience will be structurally articulated. The professional groups, it seems, should all have the same three stems: (1) cultural, (2) social and economic, and (3) technical. Merely the emphasis would be appropriately different.

The present inability completely to classify all students according to natural aptitudes should not discourage us. Such a classification is now possible to a limited degree. In any case *a* division is made; boys actually do choose to be engineers, lawyers, managers, etc., and college courses are set up to train them. A rational solution of the educational problem, it seems, can be approached only as we learn progressively to sift out types during the lower educational stages, and somehow help the individuals to find their way into activities along the lines of their natural aptitudes.

In a summary word, let us recognize the necessity of providing appropriate educational preparation for industrial management; but in our enthusiasm for this, let us not misinterpret past experience and thus fail to recognize another equal necessity; we must also provide both an appropriate educational preparation and a promising outlook for technical engineering leadership. Its contributions to technological progress surely bespeak a greater recognition than it has had. But mere justice is not the point here. It is a question whether, by a stupid perversion of emphasis now, we shall encumber the next industrial generation with the problem of a dried-up source of technical engineering leadership. Wide publicity of the new facts regarding attractive salaries in management, and the continued establishment—proper as this may be—of less exacting courses leading to management, will, it seems, inevitably discourage the more capable men from choosing technical engineering courses. The solution is not to suppress the facts or to discourage management courses, but for industry to recognize the situation, as some are beginning to do, and appropriately reward technical engineering leadership; in other words, to make such leadership a worthy and promising goal on its own score, and not merely as an entrée to general management.

# Conductor Vibration on Transmission Lines—1

**Laboratory tests reveal some interesting characteristics of conductor vibration and its effect upon conductor life; common hardware accessories, and less-common vibration dampers, are shown to have marked effects. Mathematical analyses of the stresses in standard sizes of conductors as commonly used for electric power transmission lines check closely with these stresses as measured. Field experiments in conductor vibration will be treated in another article which will appear in a subsequent issue of ELECTRICAL ENGINEERING.**

FAILURE of conductor strands from fatigue induced by vibration has occurred in widely separated places throughout the world. Although but a small percentage of the total mileage has been affected, a study of the nature of the phenomenon and means of combating it is warranted. Any suspended cable, irrespective of material, span length, tension, size, or character of supports will vibrate under certain conditions. This natural phenomenon always has occurred, but only in recent years has it been recognized as the cause of fatigue failures formerly attributed to crystallization.

About 1925 when the importance of conductor vibration began to be appreciated, Aluminum Company of America started an investigation both in field and laboratory. The early results were included in two Institute papers by Theodore Varney. In the first ("Notes on the Vibration of Transmission Line Conductors," A.I.E.E. TRANS., v. 45, 1926, p. 791), a theory of the cause of vibration was presented which has received general acceptance; in the second ("The Vibration of Transmission Line Conductors," A.I.E.E. TRANS., v. 47, 1928, p. 799), reinforcement by armor rods was proposed as a means of protection. Recently several papers dealing with vibration have been published, particularly abroad. This article summarizes and interprets the results of laboratory work conducted by Aluminum Company of America since the publication of Varney's papers. It is planned to treat the field work in a subsequent article.

The problem of eliminating vibration troubles involves the consideration of several factors. Determination of these factors demands a better understanding of:

1. The actual stresses occurring in the conductors under field conditions.
2. The fatigue or endurance limits of the conductor materials.
3. The effects of various types of conductor accessories.
4. Practical means for minimizing the effects of, or preventing, harmful vibration.

With these considerations in mind many laboratory tests have been carried out during the past 7 years, under conditions quite comparable to those in the field. While this work by no means is completed, so much progress has been made that the results obtained should be of great interest to transmission engineers.

In the vibration laboratory of the Aluminum Company at Massena, N. Y., large concrete piers are provided so that 13 different spans of conductors may be tested simultaneously. The nominal length of each of these spans is 120 ft. Total tensions up to 20,000 lb. can be maintained on each specimen by means of suitable levers and weights. In addition to these, 4 50-ft. spans are available for tests on single wires and small stranded conductors. A general view of 1 wing of the laboratory, Fig. 1, shows some of the longer spans on the left and the 4 short spans on the right. A more recent installation of vibration equipment is shown in Fig. 2. Tests on these spans utilize higher frequencies than those carried out on the long spans; frequencies used for single wires on the 4 shorter spans are still higher, sometimes being as high as 7,000 vibrations per min. These higher frequencies are made possible by mounting an unbalanced flywheel directly on the specimen as shown in Fig. 3. Motion caused by the rotation of this flywheel is restricted to the vertical plane only. Variable speed friction drives permit the use of constant speed motors. For such tests,

however, it is necessary that the speed of the driving unit remain constant within extremely narrow limits. To accomplish this it was necessary to install a special inverted motor-generator set. Many of the vibration tests have been made primarily to determine the comparative life of various sizes of conductors under severe conditions. A large mass of data is available, but the summarized results in Tables I and II for 2 sizes of A.C.S.R. (aluminum cable steel reinforced) are sufficient to illustrate several interesting facts. In the case of the 795,000-cir. mil A.C.S.R. vibrated in 7 loops on a 120-ft. span, each loop having an amplitude of $1^{1}/_{8}$ in., the marked increase in number of cycles required to cause failure as the cable tension is decreased should be noted. By reducing the tension from 18,000 to 15,000 lb. the life of the cable is almost doubled for all 3 test conditions. Similar increases were observed for still lower tensions. The data in Table II for 397,500-cir. mil A.C.S.R., vibrated under somewhat different conditions, emphasize this same fact. Further consideration of the data indicates that the outer strands must be severely stressed. This is especially evident in tests made using the square faced clamps. The repeated bending imposed on these specimens irrespective of the tensions used undoubtedly was more severe than occurs in the field.

## DETERMINATION OF STRESSES

Adequate analysis of stresses in vibration conductors includes a consideration of the general phenomenon of vibration. The studies of such investigators as Varney, Relf and Ower ("The Singing of Circular and Stream Line Wires," Aeronautical Research Committee, *Report No. 825*, March 1921), and Ryle ("Conductor Vibration," *Inst. of Elec. Eng.*, Dec. 1930) certainly have helped to make possible a better understanding of this phenomenon. To determine whether or not under any given set of conditions the fatigue limit of the material in any conductor will be exceeded, it is necessary to know the location and magnitude of the maximum stresses.

397,500 cir. mils A.C.S.R. $\left(\frac{30 \text{ x } 0.1151}{7 \text{ x } 0.1151}\right)$

Span: 120 ft. No. of Loops: 14 Amplitude: $^{9}/_{16}$ in.

| Cable Tension, Lb. | Cycles for First Failure of a Strand in the Cable | | |
|---|---|---|---|
| | Square Clamp | Bell-Mouth Clamp | Bell-Mouth Clamp With Armor Rods |
| 7,000 | 3,775,000 | 11,289,000 | 49,910,000 |
| 5,000 | | 26,380,000 | 176,100,000* |
| 4,000 | 45,316,000 | 106,210,000 | 377,000,000* |

* Test still running when this article was prepared.

If stresses exceeding the fatigue limit are repeated many times, failure eventually will occur, the time depending upon the magnitude of the stresses.

The most direct method of evaluating the stresses in a cable under given conditions of vibration is by actual measurement. While at first thought this may appear impossible because of the limitations of available strain measuring apparatus, it has been found feasible by preparing and testing special large specimens, geometrically similar to those of usual size. So far 2 such specimens of 7-strand conductors have been fabricated and tested: One is a 7-strand hard drawn aluminum cable, each wire being 0.375 in. in diameter and possessing mechanical and electrical properties identical with those of standard conductors; the other is A.C.S.R. composed of 6 strands of the same wire stranded over a single steel wire. Using a span of 120 ft., these specimens have been tested with various tensions and frequencies.

It was found that these large specimens could be set in a steady state of vibration, and the position of the top and bottom of the cable at any desirable distance from the end support determined accurately by measuring with micrometer calipers the distance to suitable reference planes. The position of the cable for different test runs could be checked within a few thousandths of an inch, and from the measurements the deflection curve for the cable could be determined accurately when vibrating as well as when not. It was then comparatively easy to displace the cable under suitable static loads to the same extreme positions it assumed while vibrating. Strains measured with the cable in the deflected positions should correspond closely with those in the cable during vibration. A comparison between the measured and computed positions of the cable near the clamped end, while vibrating, is shown in Fig. 4. Cable positions resulting from static loading are so nearly identical that the differences cannot be shown in this diagram.

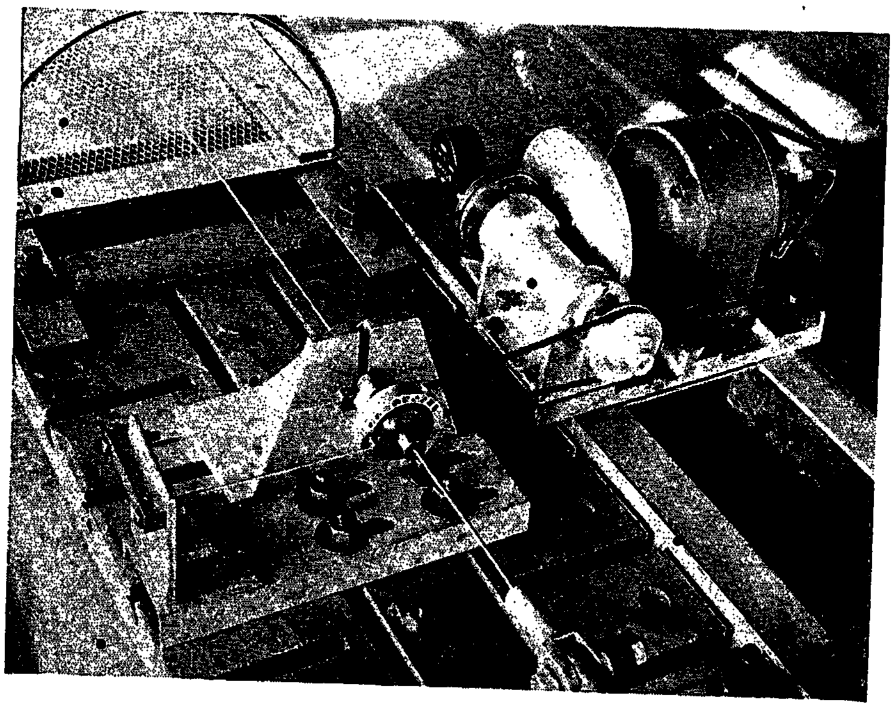

Fig. 3. Unbalanced flywheel for high frequency vibration of wires and small cables. Note variable speed friction drive

By using specimens having such large strands it was possible to attach Huggenberger tensometers, using a $^1/_2$-in. gage length, to the outside strands at various positions with respect to (1) the distance from the supports, (2) the circumferences of each strand, and (3) the circumference of the conductor as a whole. Successive applications of load together with attachment of the tensometers at various points permitted a detailed evaluation of the stresses (strains × modulus) obtaining throughout the conductor. A representative set of such data for 3 positions of the cable is plotted in Fig. 5.

## MATHEMATICAL ANALYSIS OF A VIBRATING CABLE

Formulas for the general behavior of a vibrating cable already have been given by Varney. The following mathematical analysis has been developed by R. G. Sturm of the Aluminum Research Laboratories.

The frequency at which a cable will vibrate in a loop length, $L$, is equal to

$$f = \frac{6}{L}\sqrt{\frac{Tg}{W}} \tag{1}$$

where

$f$ = frequency in cycles per sec.
$L$ = loop length or distance between node points in in.
$T$ = total tension in cable in lb.
$W$ = weight of cable in lb. per ft.
$g$ = acceleration due to gravity in ft. per sec. per sec.

Stresses from each of the following sources will be considered independently and the total stress taken as the sum:

1. Stress resulting from direct tension in the cable.
2. Bending stress resulting from the static sag of the cable.
3. Bending stress resulting from the deformation of loops during vibration.
4. Increased tensile stress caused by the increase in length of arc of the vibrating cable.

In order to facilitate following the steps in arriving at theoretical values of stress, each source of stress is considered separately.

1. Stress resulting from direct tension depends upon the ratio of steel to aluminum and to a certain degree upon the stranding of the cable. For a solid rod or for a cable in which the strands are all of the same metal this stress may be computed by simply dividing the total load by the area of cross-section, i. e.,

$$S = \frac{T}{\text{area}} \tag{2}$$

If the cable is bimetallic the stresses in the different materials and the effect of stranding may be determined as outlined by G. W. Stickley ("Stress-Strain Curves for Transmission Line Conductors," Paper No. 32-68, A.I.E.E. summer convention, Cleveland, Ohio, June 20–24, 1932).

2. Bending stresses resulting from the weight of the cable will be practically negligible throughout the central portion of the span but might be quite severe near the clamps. In general these stresses are neglected, but in some transmission lines they may be far from negligible. If the cable is clamped rigidly in a horizontal position at the end (which is probably a more severe condition than generally exists in actual service) the bending moment at the clamp may be expressed by the equation:

$$M_0 = w\left(\frac{L_s}{2K} - \frac{EI}{T}\right) \tag{3}$$

where

$M_0$ = bending moment at the clamp in in.-lb.
$w$ = weight of cable in lb. per in.
$L_s$ = span length of the cable in in.
$EI$ = flexural rigidity of the cable which depends upon the stranding conditions, but for a solid rod would be the modulus of elasticity times the moment of inertia of cross-section in lb.-in.$^2$
$T$ = total tension in the cable in lb.

$$K = \sqrt{\frac{T}{EI}}$$

The stress resulting from the bending moment, $M_0$, may be figured by the bending moment formula,

$$S = \frac{M_0 c E_0}{3EI} \tag{4}$$

where

$E_0$ = modulus of elasticity of the material in the outer strands in lb. per sq. in.
$EI$ = flexural rigidity of the cable in lb.-in.$^2$
$c$ = half of the outside diameter of the cable in in.

The value of $EI$ for a stranded cable cannot be determined analytically because of the interplay of the strands upon one another. The effect of the stranding is not entirely independent of the tension applied to the cable and, therefore, must be determined for the average working tensions under which the cable will be used.

In order to determine the values of $EI$ for stranded cables, load-deflection tests were made on the center section of a long cable. A span length of at least 6 times the lay of the cable was chosen in the center portion of the span. Supports were blocked up under the cable and the cable clamped to the supports after the tension had been applied. Transverse load then was applied to the midpoint of this secondary span and deflection readings taken for increments of load. Ordinary beam formulas for determining these deflections no longer hold because of the relatively large direct stress in the member. Setting up the differential equation representing equilibrium and continuity in the beam, it is found, however, that

$$\frac{d^2y}{dx^2} - \frac{T}{EI}y = \frac{M_0}{EI} - \frac{PL}{4EI} + \frac{Px}{2EI} \tag{5}$$

where

$P$ = load at the center of the intermediate span in lb.
$y$ = deflection in the direction of the load in in.
$x$ = distance from the left end of the intermediate span in in.

and other terms are as previously defined.

A solution of this equation gives not only the shape of the deflected cable but also the equation for bending moment at every point in the cable since

$$M = EI\frac{d^2y}{dx^2} \tag{6}$$

The boundary conditions that must be satisfied are that the deflection at the clamped ends be zero; the slope at the clamped

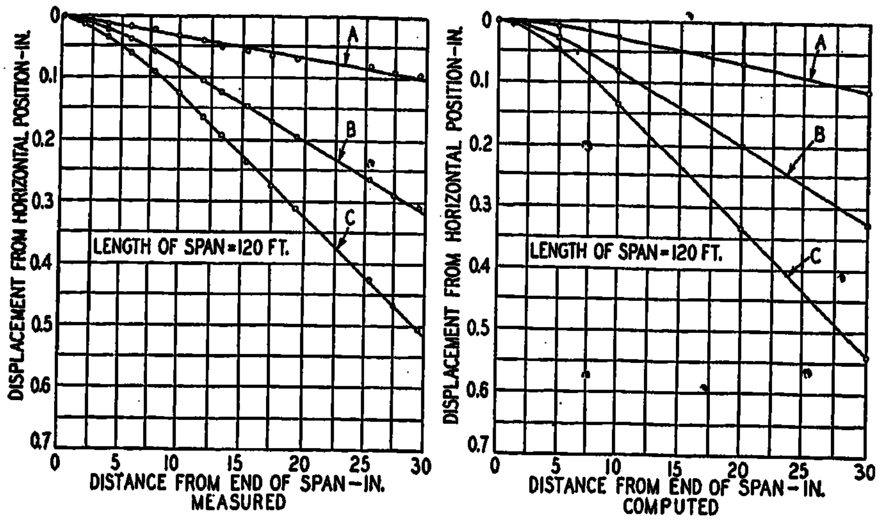

**Fig. 4. (Left) Comparison of measured and computed deflections of cable. Measured values are shown at the left; computed values, at the right**

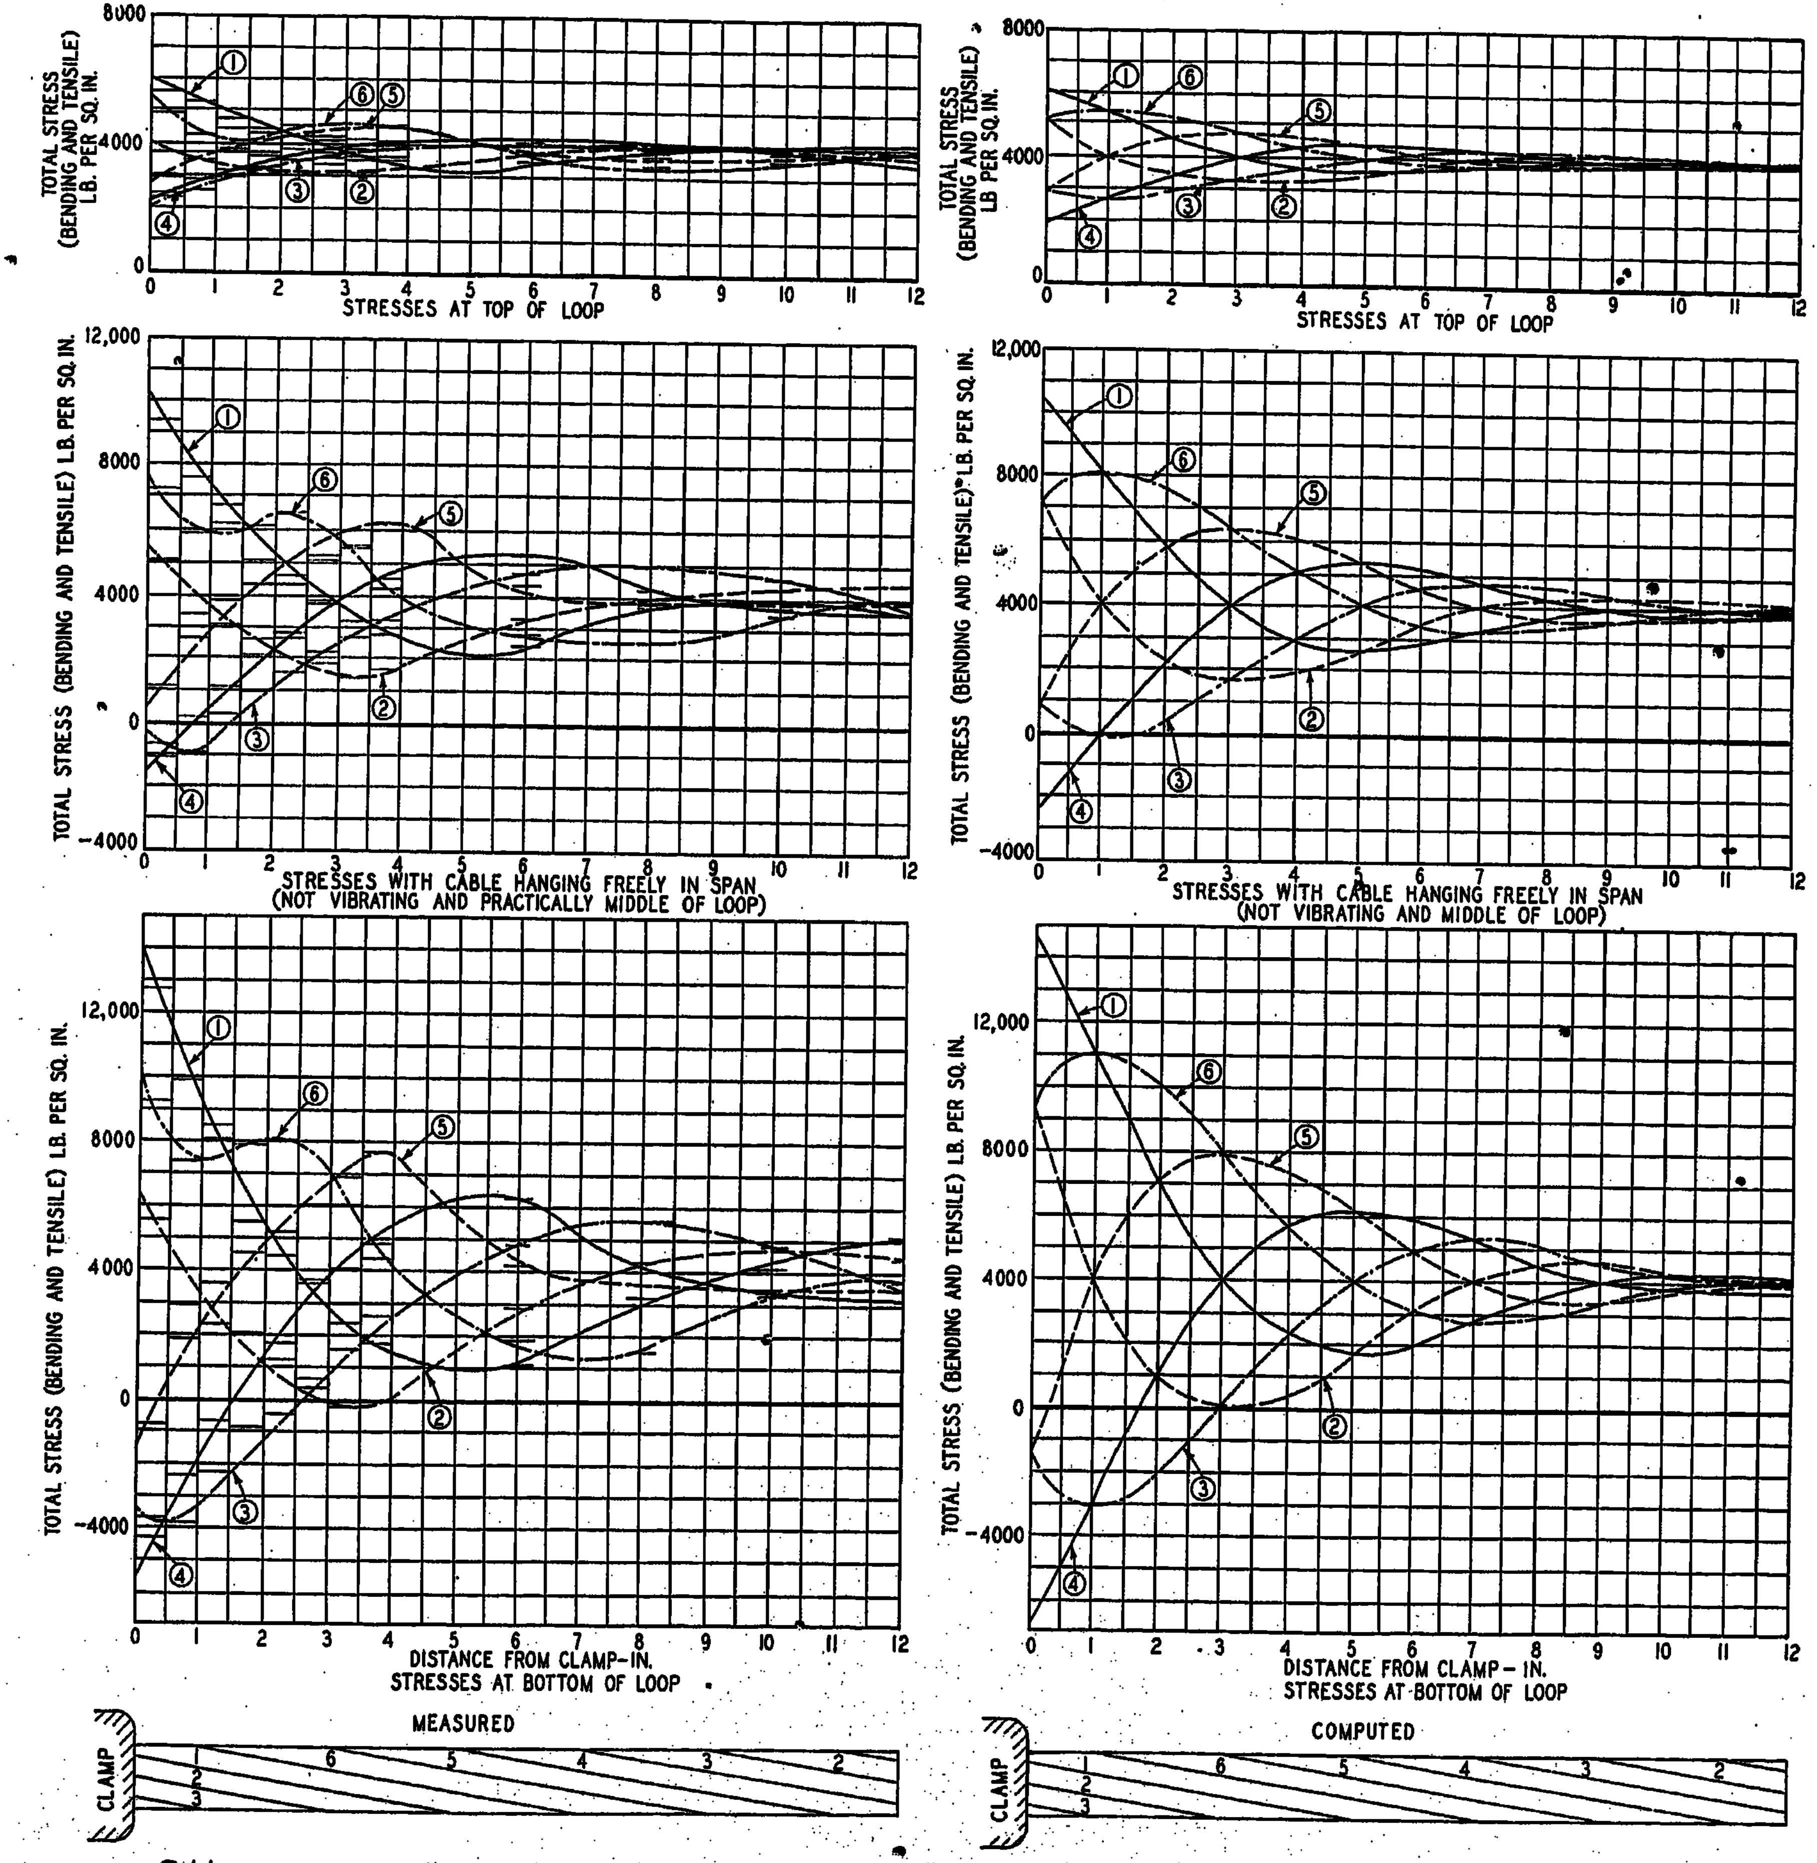
A—Upper position when displaced either statically or by vibration (7 loops—1 1/8-in. amplitude)
B—Natural or free position of cable
C—Lower position of cable when displaced either statically or by vibrations (7 loops—1 1/8-in. amplitude)

**Fig. 5. (Below) Distribution of stress in the strands of a typical cable. Measured values are shown at the left; computed values, at the right**



Cable tension 6,000 lb.
Tensile stress in aluminum 4,000 lb. per sq. in.
Length of span 120 ft.
Length of lay of cable 12 in.
Clamp at end of span square

Stresses in the different strands of the cable at the top and at the bottom of the loop, respectively, were determined for the cable deflected statically to the same position as when it was being vibrated in 7 loops and with 1 1/8-in. amplitude end, zero; and the slope at the middle of the span, zero. The resulting solution gives

$$y \doteq \frac{P}{2KT\left(e^{\frac{-KL}{2}}+1\right)}\left[-e^{-Kx}+e^{-K\left(\frac{L}{2}-x\right)}-1+e^{\frac{-KL}{2}}\right]+\frac{PL}{4T}-\frac{Px}{2T} \tag{7}$$

Maximum deflection at the center is

$$y_m = \delta = \frac{P}{KT}\left[\frac{KL}{4}-\frac{1-e^{\frac{-KL}{2}}}{1+e^{\frac{-KL}{2}}}\right] \tag{8}$$

Knowing the load $P$ at the midspan, the tension $T$ on the cable and the deflection $\delta$ for any given span length, it is possible to determine the corresponding value of $K$ and from this the value of $EI$ for the cable. The values of $EI$ thus obtained may be tabulated for use in the stress formulas.

3. Stresses at the clamped ends or points of support caused by vibration may be computed on the basis of the static conditions that will produce a deformation of the cable identical with that occurring during vibration. It may be shown that the deflection of a span of length $L$ (the loop length) loaded with a load $P_1$, which will give a deflection equal to 0.7 times the vibration amplitude, will give the conformation desired at the clamped end. From the equation

$$\delta = \frac{P_1}{KT}\left[\frac{KL}{4}-\frac{1-e^{\frac{-KL}{2}}}{1+e^{\frac{-KL}{2}}}\right] \tag{9}$$

the value of $P_1$ which will give a deflection $\delta$, equal to 0.7 of the amplitude first is found; then the bending moment at the edge of the clamp may be computed from the formula

$$M_0 = \frac{P_1}{2K}\cdot\frac{1-e^{\frac{-KL}{2}}}{1+e^{\frac{-KL}{2}}} \tag{10}$$

where the terms are as previously defined. The stress resulting from this bending moment may be computed by means of eq. 4. It should be noted that this stress is oscillating and produces equal stress components in opposite directions on top and bottom, both being subjected to alternate tension and compression. The stresses throughout the length of cable resulting from the bending during vibration may be computed from the formula

$$S = 2\pi^2E_0\cdot\frac{c}{L}\cdot\frac{A}{L} \tag{11}$$

where $A$ = amplitude of vibration in in., and the other terms are as previously defined.

4. As the cable distorts into waves while in vibration, the length of the cable around the arcs will be greater than the length when not vibrating. The additional length thus required will result in a stretching of the cable because, in general, the clamped ends cannot yield rapidly enough. This additional length results in a unit deformation which is quite closely expressed by the formula derived by Bechtold and Folkerts ("Resistance of Cable to Transverse Vibration Especially Hollow Overhead Cable," Elecktrotech. u. Maschinenbau, July 14, 1929, p. 593).

$$\epsilon_s = \frac{8}{3}\cdot\frac{A^2}{L^2} \tag{12}$$

where $\epsilon_s$ = unit elongation of the cable, and other terms are as previously defined. The resulting stress then may be computed as

$$S = \frac{8}{3}E_0\cdot\frac{A^2}{L^2} \tag{13}$$

in which $E_0$ = modulus of the cable as a whole.

This stress is simply an increase in tension of the cable which in general is quite small but which may not be negligible in many cases.

By proper combination of all of these stresses the total stresses in the vibrating cable may be computed with a fair degree of accuracy. Stresses actually measured in a cable with those computed on the basis outlined, are shown for comparison in Fig. 5. It may be noted that stresses measured on the top part of the cable, i. e., where tensile stresses are great, are slightly lower than the theoretical stresses; whereas on the under side of the cable, where compressive stresses exist, measured stresses are somewhat greater than the computed stresses. This difference is due to the fact that the tensile stress tends to pull the strands closer together, whereas the compressive stress causes them to push out thereby tending to move the neutral axis toward the top of the cable.

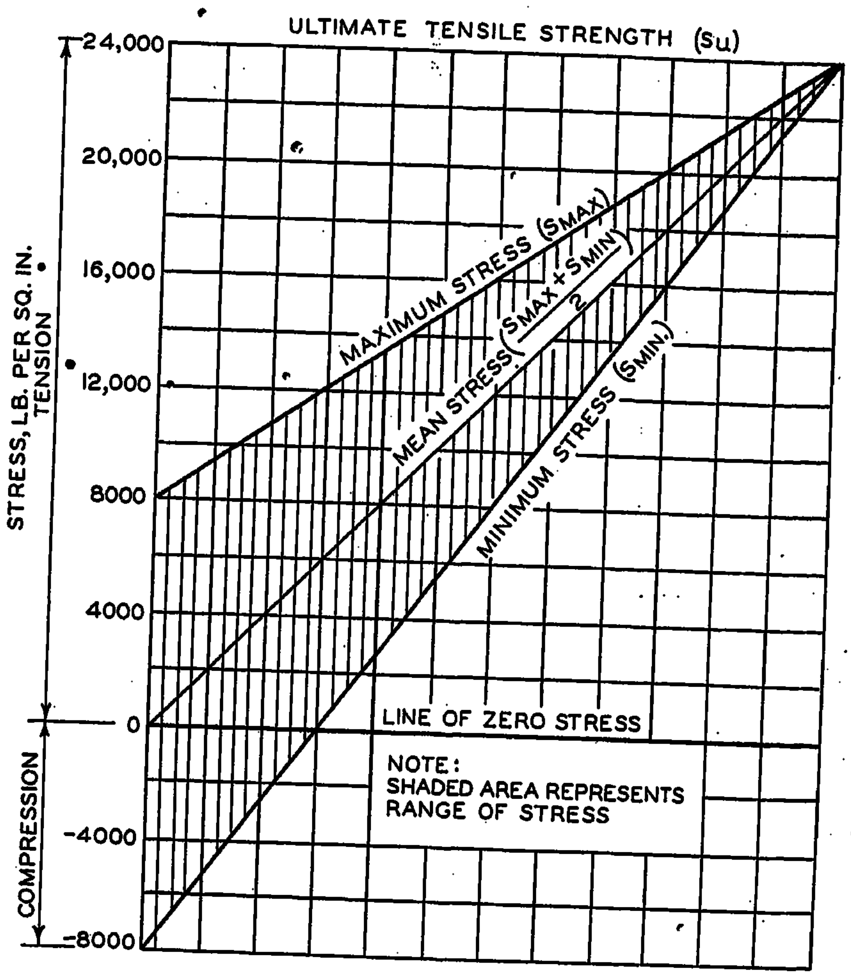


**Fig. 6. Goodman diagram showing safe mean stress and safe range of stresses for aluminum conductor**

It has been found quite feasible to measure with suitable accuracy the deflection curves and determine $EI$ values for all sizes of commercial conductors. Following the general procedure just outlined measurements of stress can be made on the smaller sizes of cable. This work is now in progress and the limited results obtained to date indicate that the theoretical analysis may be accepted with assurance.

In applying this study to transmission line problems it is important to remember that no allowance has been made for relief of stresses caused by the sympathetic motion of the cable supports. The supports used for tests were practically rigid, whereas supporting clamps and insulator ties used on actual transmission lines are far from rigid.

## FATIGUE PROPERTIES OF MATERIALS

Assuming that the limits of the stress ranges for the critical section in a cable can be determined, it is desirable to know the safe limits of the stress ranges for the materials in the cable. This information is obtained best from vibration tests of single wires under various known conditions. Such tests are essentially fatigue tests in which both the mean stress and the stress ranges may be varied widely.

Tests show that when the mean stress is zero the endurance limit based upon 500 million complete reversals is 8,000 lb. per sq. in. for hard drawn aluminum conductor metal. Using this value and the Goodman diagram which, although not checked thoroughly by experimental data, has been found to give safe values, limiting ranges of stress are obtained as shown by Fig. 6. This diagram shows that as the mean stress increases from zero to the ultimate strength of the material (24,000 lb. per sq. in.), the safe range of stress decreases from 16,000 lb. per sq. in. to zero at the ultimate strength. Tests on single wires are now in progress for the purpose of checking the Goodman diagram both for hard drawn aluminum and for steel; but because of practical difficulties in carrying out the tests, results are being obtained rather slowly.

## EFFECTS OF CONDUCTOR ACCESSORIES

Many tests have been made for the purpose of determining the effects of various types of fittings on the vibration or fatigue life of electrical conductors. Space limitations, however, permit the inclusion of only a few of the results in this article. Effects of bell-mouth clamps in increasing the life of vibrating cable are well illustrated in Tables I and II where the number of cycles for failure is shown for cable with square clamps and with bell-mouth clamps. It may be noted that the life of the cable has been practically doubled in every case. This is explained by the fact that the bell-mouth clamp prevents the severe concentration of stress that occurs in the square clamp. If armor rods are used with bell-mouth clamps the life of the cable is increased many times, as illustrated also in Tables I and II. While these tests have not been completed they have run long enough to demonstrate the effectiveness of armor rods as a means of overcoming vibration troubles.

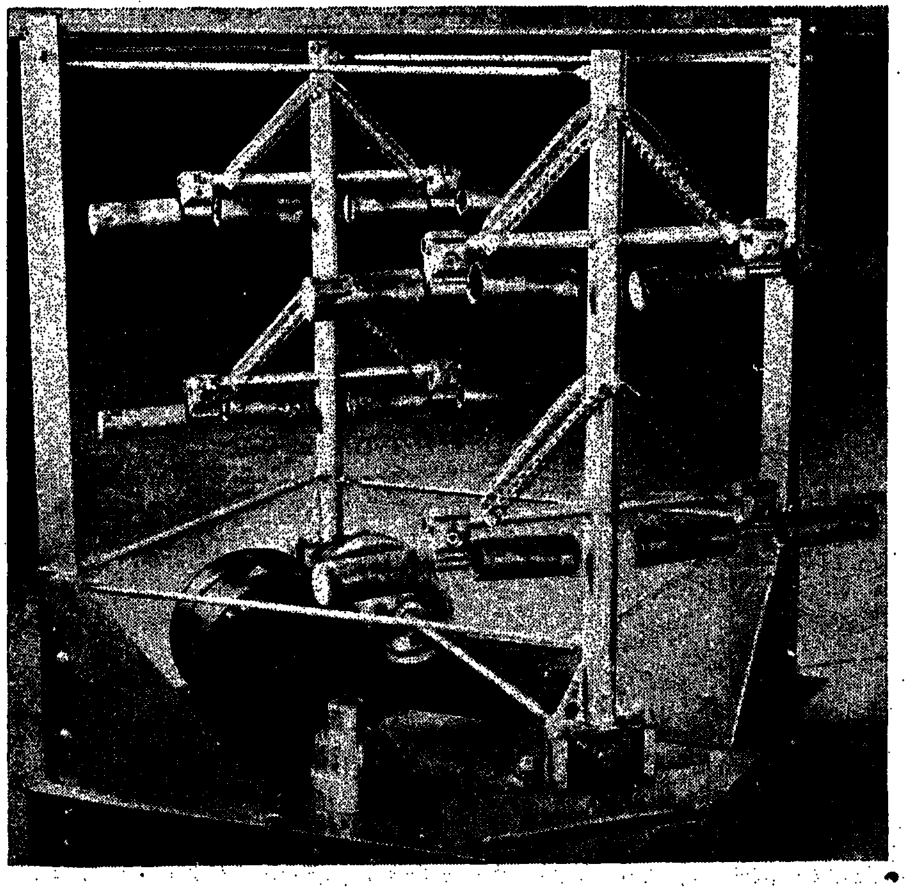

**Fig. 7. Vibration damper fatigue testing machine**

Note that the vibrating members are driven through 2 eccentrics, one of which can be seen at the lower right

It is possible by means of dampers to eliminate practically all the vibration in a cable. Laboratory work on vibration dampers has included extensive tests to determine the relative life of various dampers of the Stockbridge type using the special fatigue testing machine shown in Fig. 7. The machine can be operated at various speeds from about 600 to 1020 r.p.m. using any amplitude from zero to $1/2$ inch. Tests with this machine permit the selection of proper cable for supporting the weights and assist in refinements of design.

Another special testing machine was built for measuring the efficiency of various types and sizes of vibration dampers. This was to be done by measuring the rate of retardation of a flywheel after it and the attached damper (the damper being driven through an eccentric) were brought to a definite high speed and then disconnected from the driving motor. So far the test data have not been satisfactory for determining the efficiency of dampers, but have given valuable information relative to critical frequencies of dampers.

Dampers of the Stockbridge type (Fig. 7) have 2 critical or natural frequencies which are dependent upon the material, size, length, and stranding of the damper cable as well as upon the size and shape of the weights, and the method of attaching them to the damper cable. Computed frequencies for these devices have been found to agree with observed frequencies within the limits of experimental error. The amplitude of oscillation of the damper weights for any given forced vibration of the center clip depends upon the frequency of the forced vibration and the damping characteristics of the damper cable. With the damping characteristics of the damper cable known this amplitude may be computed and from that the energy absorbed per cycle or per second may be determined. This value together with the forces developed by the vibrating weights will give criteria for selecting the most suitable damper for any given conditions. Space limitations do not permit giving the mathematical analysis in this article.

## CONCLUSIONS

The following conclusions summarize the principal findings of the laboratory investigation treated in this article:

1. Satisfactory methods have been developed for measuring actual stresses in vibrating conductors under conditions closely simulating field conditions.
2. A mathematical analysis of the stresses in a stranded conductor under vibration is given which checks closely with measured values.
3. Tests indicate that safe limits for stress ranges of conductor materials can be determined satisfactorily.
4. Certain types of hardware accessories have marked effects upon the life of vibrating conductors.

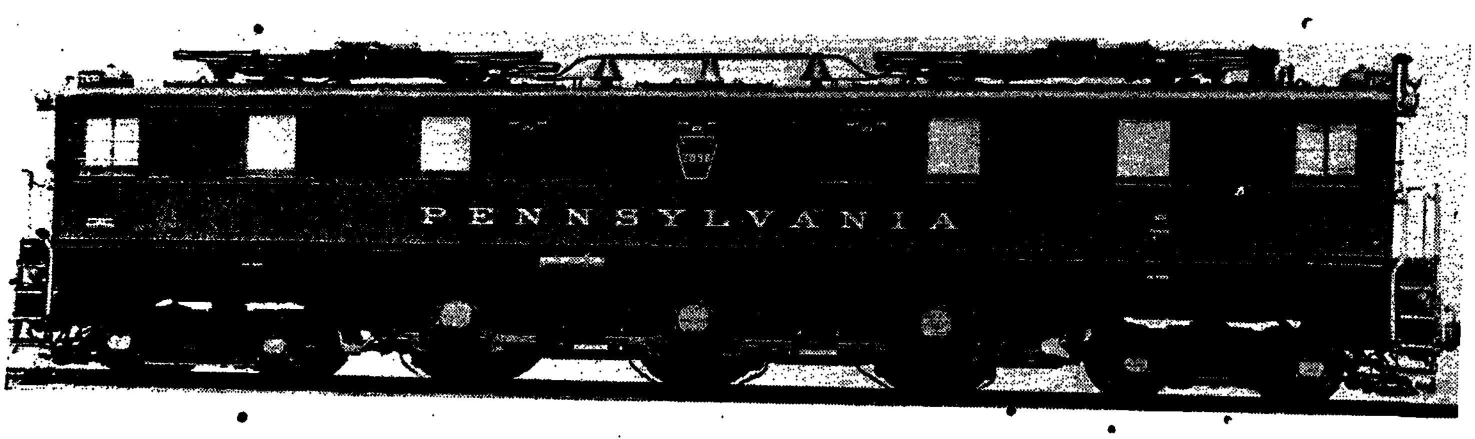
Editor's Note.—The last portion of the paper "Vibration of Overhead Transmission Lines," which deals with *field tests* on actual transmission lines, will be covered in a later article to appear in a subsequent issue of ELECTRICAL ENGINEERING.



**Heavy duty type P5 electric passenger locomotive for service on the Pennsylvania Railroad's New York-Washington line which now is being electrified**

# Electric Locomotives for the Pennsylvania

**High sustained available and controllable continuous output is considered one of the outstanding characteristics of locomotives recently designed for the Pennsylvania Railroad. This high output has been made possible by the use of motors of improved design together with transformers having suitably selected taps. Important features of these locomotives are treated in this article.**

By
J. V. B. DUER
FELLOW A.I.E.E.

Pennsylvania Railroad
Philadelphia, Pa.

HIGH sustained output, interchangeability of principal parts, accessibility of parts for inspection and repair, and the unit type of construction are some of the outstanding features of electric locomotives recently designed for the Pennsylvania Railroad for use on its New York-Washington line now being electrified. Recent advances in the design of single phase a-c. commutating motors have made it possible to mount the motors between the driving wheels, resulting in a simpler, lighter, and less expensive a-c. locomotive than had been used previously on this road. Three classes of locomotives have been designed to meet varying operating needs.

In 1915 at the time the single phase a-c. system was constructed on the main line between Paoli and Broad Street, Philadelphia, it became evident that the type or types of single-phase electric locomotives best suited for general use on the Pennsylvania system would have to be determined. Electric locomotives previously developed for this railroad were designed primarily for operation in the New York terminal area. The resulting engineering studies led in 1924 to the adoption of an electric locomotive known as the L5 type, designed primarily as a general utility locomotive for the railroad as a whole. This locomotive was so arranged that by a modification of gear ratio it could be used in either passenger or freight service; and by modification of the control, it could be used on either alternating or direct current.

After extensive tests, several of the L5 locomotives were built and placed in service in the New York electrified territory. They were designed with single phase commutating motors and control equipment suitable for operation on direct current. At the same time another was equipped for operation on alternating current and placed in service in Philadelphia.

Advances in the design of single phase motors since the adoption of the L5 locomotive have made possible the development of a simpler, lighter, and less expensive a-c. locomotive. These many improvements have been incorporated in locomotives recently designed for use on the Pennsylvania between New York and Washington. In Pennsylvania Railroad nomenclature the electric locomotives to be used in this service are designated as follows: Class P5, heavy duty passenger service; Class O1, light duty passenger service; Class L6, freight service; and Class B1, switching service.

Class B1 switcher developed some years ago has been built in quantities. It is giving satisfactory performance in both a-c. operation on the Long Island and Pennsylvania railroads, and in d-c. operation on the Pennsylvania Railroad. With slight modifications this locomotive will continue to be used for extensions in switching service.

The P5, O1, and L6 locomotives are those recently designed. This article is devoted chiefly to a description of the principal features of the P5 locomotive. The more important questions affecting the design of all 3 of the locomotives are brought out, however, and by reference to the other 2 classes the relationship between the 3 is shown. Before proceeding with the actual design of the P5 locomotive, decisions on several important questions had to be made; these are as follows:

1. Weight on drivers.

After study and review of steam locomotive practise, it was decided to aim at a weight of 75,000 lb. per pair of drivers and a total locomotive weight of 375,000 lb. Consideration was given to the mechanical structure of the locomotive, the speed at which it was to operate, and to the structures and physical characteristics of the railroad over which the locomotive would be used.

---

Written especially for ELECTRICAL ENGINEERING; based upon an oral presentation before the transportation group of the A.I.E.E. New York Section. *Not published in pamphlet form.*

### 2. Selection of electrical equipment.

Single phase commutating type motors were selected for driving the locomotive. In selecting these as well as the other electrical equipment, consideration was given to the best method of taking full advantage of the permissible weight on drivers, both in regard to horsepower and tractive effort, and to secure a proper balance between these factors and the capacity of the electrical equipment.

### 3. Horsepower and tractive effort.

In deciding upon these features, consideration was given to the horsepower and tractive effort of a steam locomotive that was handling through passenger trains successfully; it was felt that if an electric locomotive could be built with the same or better horsepower and tractive effort than that of this particular steam locomotive, the resulting electric locomotive would provide a satisfactory unit for handling through passenger trains.

### 4. Maximum speed.

To provide operating tolerances over present speed, and at the same time permit increased operating speeds in the future should they prove justifiable, a maximum operating speed of 90 miles per hr. was selected.

### 5. Adhesion factors.

Conservative design required the use of an adhesion factor of 25 per cent of the weight on the drivers. Experience with electric locomotives in the past indicated that this adhesion factor could be reached without trouble under almost any normal operating conditions.

In the earlier Pennsylvania locomotives of both a-c. and d-c. types, for various reasons jack shafts and side rods had been used as the means of transmitting the motor output to the driving wheels. In d-c. locomotives this was done to secure a smooth riding vehicle as well as to concentrate the driving power in a small number of large motors. In the a-c. locomotive, similar construction was used to permit the use of a minimum number of large motors, since, when these locomotives were designed it was not possible to place between the driving wheels sufficient motor capacity to handle the tractive efforts made available by the permissible weights on drivers. Developments in single phase motors, however, now permit the installation between the driving wheels of sufficient motor capacity to handle effectively the maximum weight per pair of drivers; jack shafts and side rods thus are no longer necessary, and it is possible now to design a maximum driving unit of sufficient capacity to develop the tractive effort available with the allowable weight per driving axle.

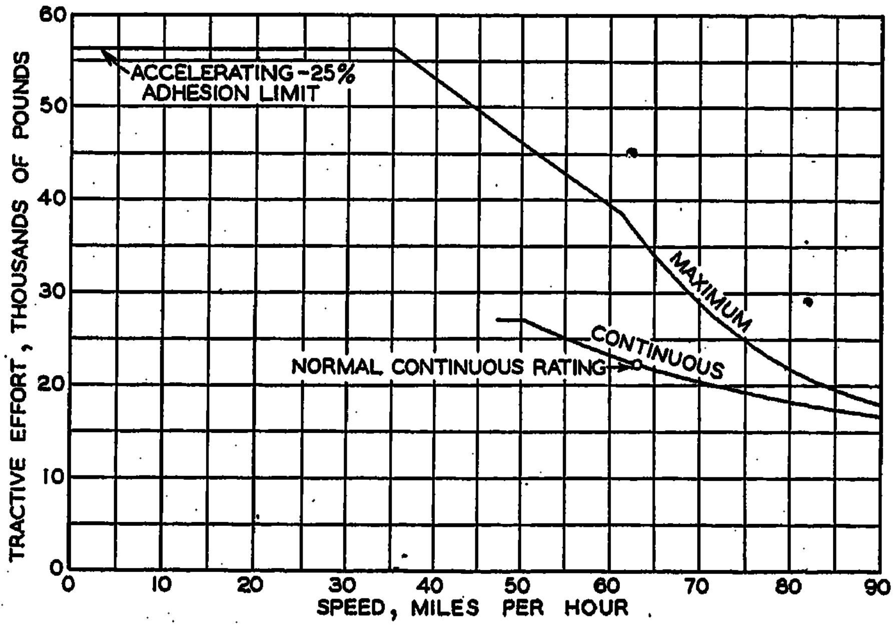
## IMPROVEMENTS IN A-C. LOCOMOTIVE MOTORS

Among developments that have made possible the increase in motor capacity referred to, may be mentioned an increase in permissible peripheral speed of both armature conductors and commutator. This increase in safe peripheral speed resulted from improvements in the mechanical design of both armature and commutator, the use of roller bearings for the armature, and improved mechanical design of gears and pinions. Another development that has contributed to the increase in motor capacity is an increase in the efficiency of forced ventilation, which has followed upon a detailed study of air distribution through the various air passages in the motor windings.

With the selection of this improved driving unit as a base, it has been possible to design locomotives of different classes for freight and passenger service, each with a suitable multiple of these driving units assembled in combination with appropriate idle trucks. Thus in the P5 locomotive, a motor unit consisting of 2 armatures and stators in a single frame was selected as the motive power for a pair of drivers, the motors driving the wheels through an adaptation of the well-known quill drive. In the O1 locomotive, identical units are used with fewer drivers. In the L6 locomotive, single motors mounted in a frame suitable for axle mounting drive the wheels by means of conventional gear reduction arrangements.

As the design of the P5 locomotive progressed it was found that 3 pairs of drivers, each pair equipped with the motor unit just described, with a 4-wheel truck at either end of the locomotive, provided somewhat greater capacity than the present through steam passenger locomotive known as the "Pacific" type. It was found also that an assembly of 2 sets of twin motors with 2 pairs of drivers and a 4-wheel truck at either end, classification O1, provided a locomotive of somewhat greater capacity than the through steam passenger locomotive known as the "Atlantic" type. An assembly of 4 pairs of drivers of approximately 60,000 lb. per pair having a single armature driving each pair through gears and pinions, with a 2-wheel truck at either end of the locomotive, provided a capacity somewhat greater than that of the "Mikado" steam locomotives used in freight service on the Pennsylvania system.

In addition to the foregoing, the designs selected permitted great flexibility of motive power: In an O1 locomotive, 2,500 hp. is available with 2 pairs of drivers; in the P5 locomotive, 3,750 hp. is available with 3 pairs of drivers; in 2 O1 locomotives, 5,000 hp. is available with 4 pairs of drivers; in a combination of an O1 and a P5 locomotive, 6,250 hp. is available; and in 2 P5 locomotives, 7,500 hp. Thus it is possible to increase locomotive capacity in steps of 1 pair of drivers, or 1,250 hp., and to select the proper unit for almost any weight or size of passenger train now used on this railroad or likely to be used in the near future.

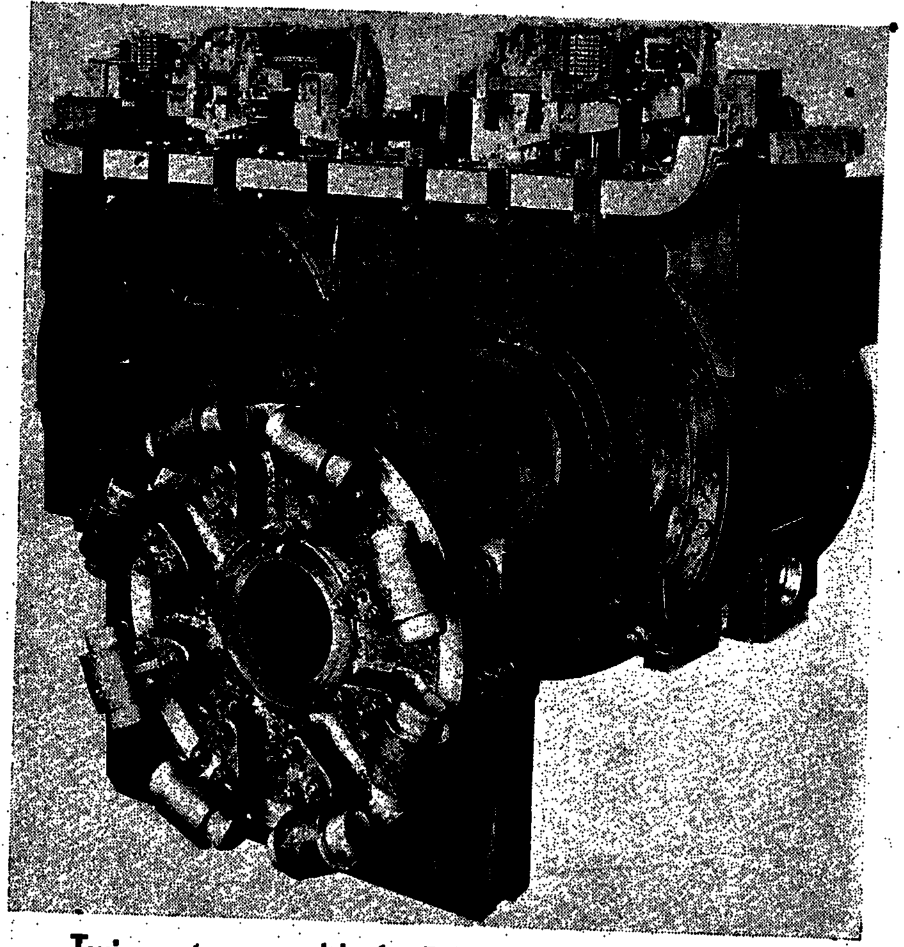


**Speed-tractive effort characteristics of the P5 electric locomotive**

While the freight locomotive's capacity cannot be increased in such steps, a careful study of freight service on the Pennsylvania has indicated that the unit selected is the best all-around one for handling freight trains on this system and that the steps in which the capacity can be increased are sufficiently flexible.

## Unit Construction Used

Experience with construction and maintenance has indicated that in any class of electric locomotive, any part should be readily removable and replaceable, and that in so far as possible, all parts should be interchangeable between individual locomotives of the same class. The desirability of still further applying this principle between different classes of locomotives is evident. With the cooperation of the manufacturers, this has been accomplished in the P5 locomotive. Any unit or part, armature, motor, brushholder, transformer, or control unit, will fit and perform properly in any locomotive assembly regardless of the manufacture of other parts in that assembly. This principle has been developed further in the locomotive assemblies in that each complete assembly consists of 3 units, a chassis, an apparatus deck, and a cab.



Twin motor assembly for P5 locomotive, pinion end, showing quill drive

*Chassis.* The chassis unit consists of the drivers, trucks, main frame, spring rigging, brake rigging, motors, flexible drives, main transformer, and train heating boiler, together with the necessary water and oil storage reservoirs, and air, oil, and water piping. Foundation for the chassis unit is a single steel casting into which are cast the oil and water reservoirs of the oil-fired steam boiler, as well as reservoirs for compressed air for the brake and control systems. At each end of this steel casting is a 4-wheel engine truck consisting of a single cast steel frame, a steel bolster casting, and the necessary spring and brake rigging.

All driving wheels, truck wheels, and motor armatures are mounted in anti-friction bearings. This type of bearing has been used extensively on this railroad for passenger car journals and for traction motor bearings; it is anticipated that by extending the use of these bearings to the driving wheel journals, truck wheel journals, and motor armatures, bearing trouble will be practically eliminated and locomotive maintenance expense materially decreased.

*Apparatus Deck.* This unit contains the main control groups, air compressor, miscellaneous apparatus, main wiring, and most of the control wiring. Foundation for this unit is a structural aluminum framework upon which the electrical equipment is assembled and wired. The assembly then is mounted as a unit directly on the chassis.

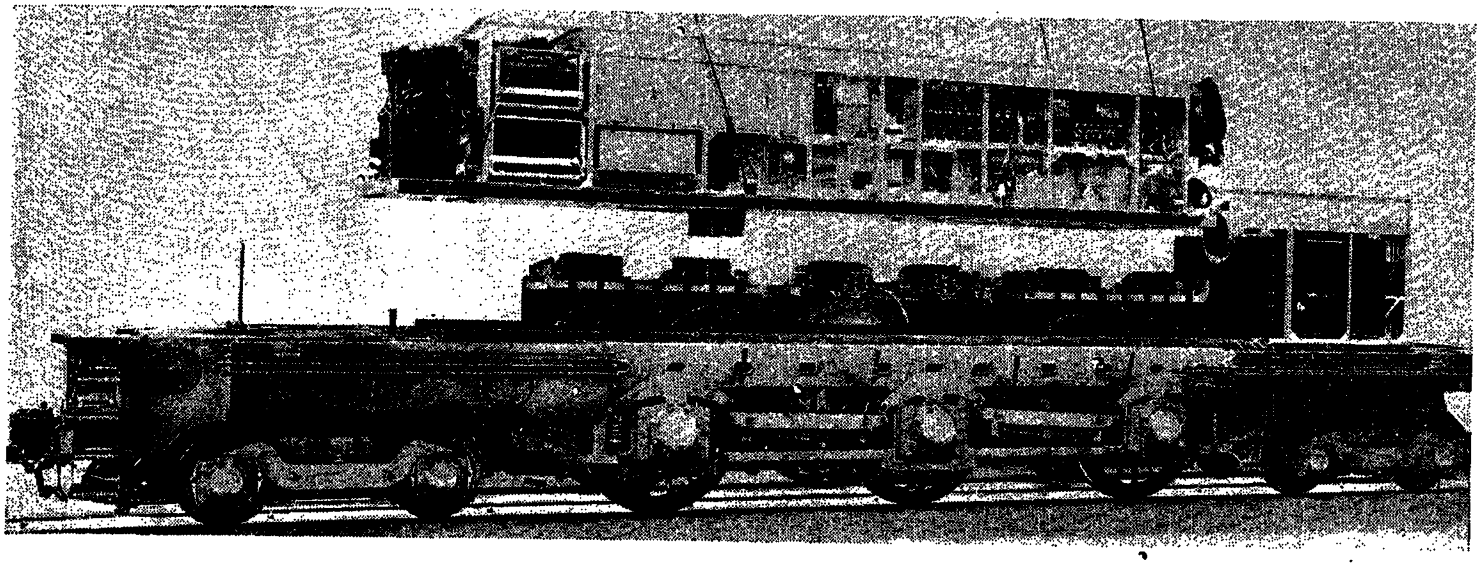
*Cab.* This unit forms a weatherproof housing for the locomotive crew and apparatus. The foundation is an aluminum structure divided into 3 compartments, a booth for the locomotive enginemen at either end, and a central compartment covering the apparatus deck. This unit houses also the heating boiler, main transformer, master controllers, the engineer's brake valves, some of the control wiring, and other miscellaneous accessories, and supports the pantographs, bell, and whistle. Louvers in the sides of the cab admit ventilating air to the motor and transformer blowers. The entire cab may be assembled as a unit, wired, and equipped with apparatus, then mounted directly on the chassis and over the apparatus deck.

Each of these 3 units of a locomotive may be assembled independently of the other, then assembled together into a complete locomotive. Parts such as a pair of drivers with motors and driving mechanism, a truck, or a control unit, may be removed and replaced with a minimum of disturbance to the rest of the locomotive.

Class O1 locomotive is in all respects similar to the Class P5 except that it has 2 driving axles instead of 3 and consequently is of smaller capacity. Equipment in the 2 locomotives is similar in every respect except that the transformer in the O1 is of smaller capacity.

Class L6 freight locomotive has 4 driving units with a 2-wheel truck at either end. Each driving unit carries but 1 motor armature with its frame, each motor being axle-borne, much in the manner used for years on trolley cars. The single motors of the L6 locomotives, however, are identical except for the frame, end housings, and pinion end bearings, with the motors of the twin units used in the passenger locomotives. In the L6 locomotive the cab and apparatus deck is of steel, as weight restrictions do not necessitate the use of aluminum.

Thus it may be seen that the P5 has 6 motor armatures, the O1, 4, and the L6, 4 motor armatures. All of these motor armatures are alike; also all twin frames are alike, as are all single frames. These motors have been rated nominally at a continuous output of 625 hp. per armature at the locomotive



Apparatus deck completely equipped being lowered upon the chassis of a P5 electric locomotive. Note unit construction. After the apparatus deck is secured to the chassis, the cab unit is added to complete the locomotive

driver rims; this gives a nominal continuous rating for the 3 classes of locomotives as shown in the accompanying tabulation.

**Ratings of New Locomotives for Pennsylvania Railroad**

| Class | Hp. | Speed in Mi. per Hr. | Tractive Effort in Lb. |
|---|---|---|---|
| P5* | 3,750 | 63.0 | 22,300 |
| O1 | 2,500 | 63.0 | 14,900 |
| L6† | 2,500 | 37.8 | 24,800 |

* Geared for a maximum speed of 90 mi. per hr.
† Geared for a maximum speed of 54 mi. per hr.

With the foregoing general description of the locomotives in mind, it may be interesting to dwell upon some of the more important details.

### PRINCIPAL PARTS INTERCHANGEABLE

Interchangeability of parts has been referred to previously in this article, but the extent to which this interchangeability has been effected has not been treated in detail. It may be said that in the 3 classes of locomotives, the interchangeability of electrical parts is practically complete. The unit switches, master controllers, air compressors and motors, pantographs, blowers for motor ventilation, and relay systems, are identical. The preventive coils and transformers are identical on O1 and L6 locomotives, but are larger on the P5 locomotive because of the greater capacity required.

Although the assembled motors on the O1 and P5 locomotives are of the twin-armature frame-supported type and those on the L6 locomotives are of the conventional single-armature axle-supported type, the individual parts of the motors, including armatures and stators, are identical except that a larger pinion bearing is used in the axle supported motor to take care of the higher duty required by the freight gearing. The same stators may be pressed into or out of either type of frame.

Mechanical parts of the O1 and P5 locomotives are interchangeable to a large extent; driving wheel assemblies including bearings are the same as are the truck assemblies; also many parts of the spring and equalizing rigging and of the brake rigging are identical. Furthermore, many of the parts used to make up the apparatus decks and cab structures are the same.

### ACCESSIBILITY AIDS INSPECTION AND REPAIR

Accessibility of apparatus for inspection and repair also has been mentioned. This was the subject of continual study during progress of design, and every effort was made to insure that each piece of apparatus is not only readily accessible for inspection but also readily removable for repair. Thus a locomotive may have a defective piece of apparatus replaced and be returned to service in the minimum time. For this purpose hatches are provided in the cab roofs of all 3 classes of locomotives. Through these hatches any piece of apparatus inside the cab may be removed readily for repair or replacement.

A complete driving wheel assembly, including the motors, may be dropped from the frame in the repair shop and replaced in a relatively short time, thus making all electrical parts of the locomotive readily accessible and renewable either from above or below. In addition to this, each piece of apparatus inside the cab may be inspected readily from the interior; commutators and brushholders of the main motors may be inspected equally readily from the inspection pit.

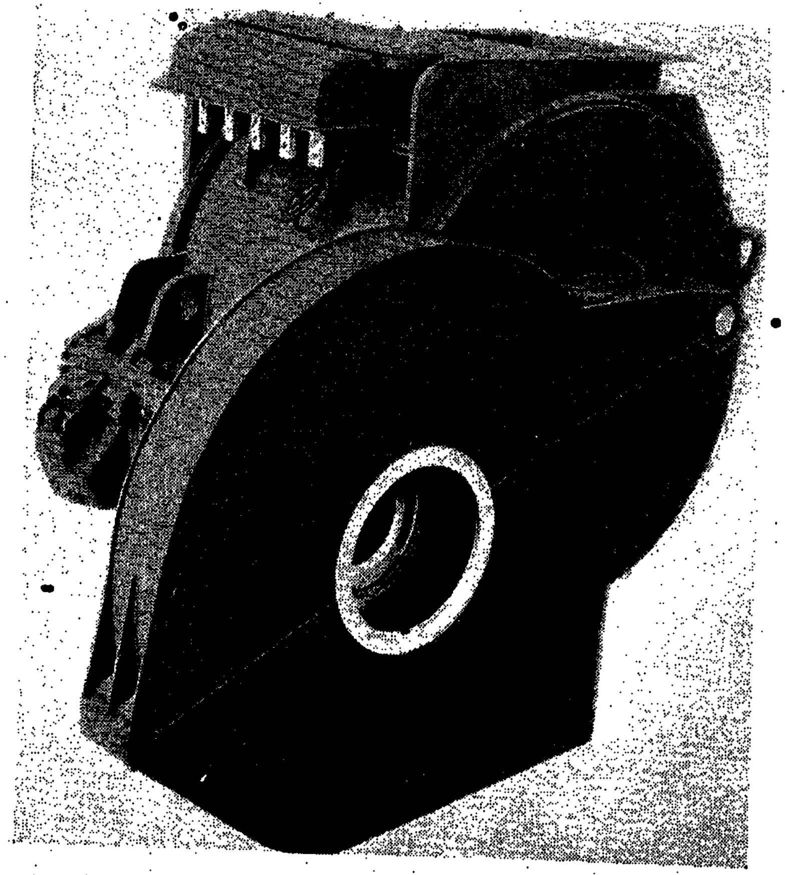
Handling the large quantity of ventilating air necessary for cooling the motors and transformers was made the subject of detailed study. In the final design louvers are provided in the sides of the cabs that may be opened or closed, depending upon weather conditions. These louvers are so designed and constructed that screening devices may be applied should further operating experience indicate that such devices are necessary.

### TYPE OF DRIVE USED

The type of drive to be used between the pinion driven gear of the armature and the driving wheel has been the subject of much detailed study and analysis; several types of drives have been built and placed in service and on test. These tests still are proceeding, however, and final decision on this question will follow at a later date. The first 90 passenger locomotives built will be equipped with the cup drive shown in one of the accompanying illustrations; so far this drive has given excellent results in service. In the freight locomotives, the conventional arrangement of pinion and flexible gear used largely in multiple unit car construction and in previous electric locomotives has been adapted to the tractive efforts and speeds of the freight locomotive.

### ELECTRICAL PROTECTION

For some years it has been the practise of the Pennsylvania Railroad to omit the use of a current rupturing device between the pantograph on an electric locomotive and the primary of the main transformer, and to substitute in its place a device known as a pantograph lowering relay. This relay is connected so as to use the substation circuit breakers to open high voltage short circuits, grounds, or overloads on the locomotive. In the P5, L6, and O1 locomotives this device has been supplemented by an automatic grounding device. Should a transformer short circuit or overload condition develop, this device will function automatically to ground the pantograph, thus opening the substation circuit breakers, after which the pantograph is lowered and locked automatically by the lowering relay.



Axle hung motor for L6 freight locomotive, showing gear case

Protection against motor overload is provided by relay devices, thus permitting the utilization of the maximum tractive effort made available by driving wheel adhesion, at the same time affording protection for the motors should this adhesion exceed normal values due to the application of sand or mishandling of the equipment. This relay protection also is interlinked with anti-wheelslip protection which insures driving wheel slippage being brought to the engineman's attention should he otherwise not detect it.

While it would be possible to enter into considerably more detail in regard to the various features of the design and equipment of these locomotives, such detailed treatment obviously would be beyond the intended scope of this article.

# Wire Communication Aids Air Transportation

**Through government aid, great progress has been made during recent years in reducing the hazards of bad weather to air transportation. Practically continuous reporting of meteorological information and weather forecasting along the principal airways is carried on with the aid of extensive teletypewriter network.**

By
H. H. NANCE
MEMBER A.I.E.E.

American Tel & Tel. Co.,
New York, N. Y.

RAPID DEVELOPMENT of air transportation in this country has continued through the past few years so that today established routes connect nearly all important cities. Route mileage of airways in the United States as shown in Fig. 1 totals over 30,000 miles. Regularly scheduled transport service is given on practically all of these routes; in addition, the routes are used to a considerable extent by military and private planes.

Statistics relating to service of air transport companies seem particularly significant: The United States Department of Commerce reported approximately 42,800,000 miles flown in passenger, mail, and express service on domestic scheduled lines in 1931, an increase of 35 per cent over the preceding year and more than a fourfold increase since 1928. In the same 3-year period passengers carried increased ninefold, reaching a total of about 470,000 in 1931. Along with this growth, safety has been increased as is indicated by the respective 1928 and 1931 reports of 250,000 and 750,000 miles flown per accident. Reasonably regularity of schedules on air transport lines also has been maintained, the ratio of miles actually flown to scheduled miles last year being of the order of 92 per cent.

Communication facilities have been an important contributing factor to all this development and improvement. It was recognized early that fast and reliable communication would be needed in connection with any extensive development of air transportation. Communication with planes in flight was an obvious requirement; this could be provided only by radio. For land service, however, experience has indicated that wire facilities best meet the general requirements. This article de-

---

Based upon "Wire Communication Aids to Air Transportation" (No. 32-82) presented at the A.I.E.E. Summer convention, Cleveland, Ohio, June 20-24, 1932.

scribes the wire communication facilities in general use today, both by the government and by transport companies, as aids to air transportation.

Principal airways have been established largely through federal aid. In addition to marking and lighting airways the airways division of the United States Department of Commerce had provided up to April 1, 1932, 67 radiotelephone stations at approximately 200-mile intervals (see Fig. 1) to be used for broadcasting weather reports and similar information to planes in flight and for transmitting directive radio beacon signals for enabling planes to keep on the course. In conjunction with these services the airways division had contracted for 24-hour teletypewriter service along 13,000 miles of main airways connecting some 250 stations, principally for the purpose of transmitting weather reports and to assist in dispatching the planes. All of these facilities have been made available without cost to aircraft operating companies and others using the airways.

In addition to the communication service contracted for by the government, approximately 5,000 miles of teletypewriter circuit are used daily in furnishing private wire communication service to several transport companies for transmitting information pertaining to the operation of their own lines. Routes on which these facilities are furnished to the government and transport companies are indicated by heavy lines in Fig. 1.

When the first air mail service was established, radiotelegraph was introduced as a means of point-to-point communication along the New York-Chicago-San Francisco airway route. At each radio station meteorological data were collected from surrounding points by means of long distance telephone and telegraph; these data were exchanged periodically through the day with the other stations over the radiotelegraph. With a rapid expansion in air transport service foreseen it was apparent that a large increase in communication facilities would be needed. There was the definite requirement for radiotelephone communication with planes which would need several radio channels allotted to this service. Considering these factors and the geographic and other conditions, it seemed that regular point-to-point service served by radiotelegraph could be provided more satisfactorily in another way.

Arrangements were made in 1928 for teletypewriter communication at several points connecting radio stations with their local weather bureau offices in order to expedite the delivery of weather reports and other traffic handled by radiotelegraph. Shortly afterward, a teletypewriter system was installed on the New York-Cleveland route connecting the Department of Commerce and weather bureau stations at Hadley Field, Shelton, N. J., and Cleveland, Ohio, and several intermediate points. This type of service seemed ideally fitted for use in weather reporting and plane dispatching and has been extended not only to replace the service previously furnished by radiotelegraph, but also to provide for communication requirements of other routes.

Teletypewriter service offers the advantages of simultaneous communication with any desired num-

ber of stations, the communications being automatically recorded at each point. A message using code or abbreviations can be sent instantly without the necessity of calling or checking with the receiving stations, thus requiring the immediate attention of only the sending operator. Automatic recording reduces the possibility of human error and permits the most efficient use of operating personnel with resulting savings in labor. Furthermore, as contrasted with radio, this system utilizing wire transmission is not so subject to variations in meteorological conditions; it is thus more dependable, and has the further advantage that it can be extended readily to handle large volumes of business. This system also is well adapted to carrying on administrative and other work as well as to weather reporting and plane dispatching.

## Transmission of Weather Reports

Notable progress has been made in reducing the effect of weather hazards to air transportation, through the service rendered by the United States Department of Commerce and weather bureau in the collection and dissemination of weather reports, supplemented by other reports collected by individual transport companies from planes in flight. A system of practically continuous reporting and forecasting for areas along air routes has been developed, and general weather observations have been extended to include data of particular benefit to air navigation. The teletypewriter networks furnished to the Department of Commerce are devoted largely to this purpose; in conjunction with the department's radio telephone broadcasting service these networks provide the means for furnishing to pilots information relating to existing conditions and forecasts for both general and local areas.

Twelve selected weather bureau airport stations located at strategic points in the country's airway network prepare summaries of weather conditions in their own areas and make area forecasts every 3 hours based upon data collected over the Department of Commerce circuits from connected airway stations, and over commercial telegraph lines from other reporting points. These summaries and forecasts then are transmitted over the teletypewriter circuits and made available to all airway stations.

While the forecasts include predictions as to storm developments or movements, conditions in specific localities often are likely to change rapidly; hence to keep pilots continuously advised of conditions likely to be encountered, it has been necessary to provide additional hourly reports along the air routes. Consequently, the airway keepers and weather bureau observers at the various teletypewriter stations make local observations of general weather conditions, ceiling height, visibility, wind direction and velocity, temperature, and barometric pressure, every hour. These data then are sent by the teletypewriter and automatically recorded at all points on the circuit in accordance with a predetermined schedule, which is coordinated with the broadcast schedule of radio stations. Since pilots will tune in on particular stations at definite times, it is important that the schedule be adhered to closely.

Fig. 2 shows a portion of an actual tape record of an hourly report along the Newark-Cleveland route. For convenience the tape has been cut to show 1 station report on each line. First, the starting time, 0642 E. S., which is 6.42 a.m. Eastern Standard time, is shown. This is followed by a report of observations from each station given in sequence. The time of actual transmission for all 14 stations, Newark to Cleveland, would be about 4 min. and at 6.50 a.m. the reports would be broadcast as scheduled from the radio stations on that route.

Based upon the information obtained through the sequence collections, the airway weather reporting stations retransmit, generally by teletypewriter, hourly weather reports to the various airway operating companies' offices in that vicinity where the information is posted for convenience to pilots. An experimental service involving the transmission of weather summaries in map form was tried out recently at Kansas City, Chicago, Cleveland, Newark, and Washington. A separate circuit equipped with page teletypewriters at each of these points was provided for this purpose. The weather maps were prepared at Kansas City and Cleveland every 3 hours and then transmitted over this circuit. A typical map transmitted from Kansas City is shown in Fig. 3. The map data are sent in sequence from the 2 transmitting stations; after they have been recorded on the map forms at the receiving station several duplicate copies can be run off immediately and the 2 maps fitted together if desired. The maps then are available to pilots at each of the respective airports.

Complete reports of weather generally are maintained by transport companies in dispatching offices. On some lines 2-way short-wave radiotelephone equipment has been provided for communicating with planes, periodic contact being maintained during flight. In this way pilots report their positions directly to dispatchers; in addition supplementary weather data usually are exchanged, particularly with respect to local ceiling heights and conditions in the upper air strata.

## PLANE DISPATCHING AND OTHER SERVICE

Teletypewriter circuits furnished to air transport companies are used principally for dispatching planes and handling the many traffic matters usual to this type of service. Plane movements including reports of position in flight are transmitted over the teletypewriter system and recorded at various offices, the reports of positions in many cases being given by pilots over short-wave radiotelephone where this type of equipment has been provided.

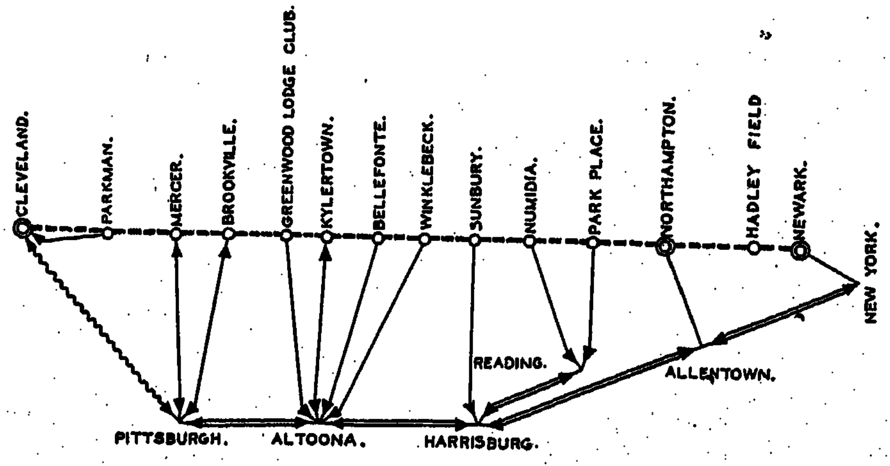

**Fig. 4. A typical teletypewriter circuit for airway service**

Intermediate airway stations often are situated some distance from main communication lines. A total of 846 miles of line thus is required to serve this 400-mile airway

To facilitate position reporting some of the companies have superimposed a system of rectangular coordinates over a map of the course cutting the territory into squares or rectangles 10 to 20 miles on a side. The coordinates are numbered so that the pilots and dispatchers can establish readily the location of the plane. Dispatchers generally maintain a typewritten, chronological log of position reports from each plane in the air. Bulletin boards also are used, marked with stations along the route and with spaces for filling in data such as plane number and license, name of pilot, time of arrival and departure at each station, and final destination.

On large lines a great deal of information is required to be transmitted in connection with the handling of traffic. Usually this consists of data concerning reservations, number of passengers and amount of mail and express carried, connections to be made, and arrangements at terminals. Supplementary instructions to pilots and many administrative matters requiring prompt handling also are transmitted.

Although airways teletypewriter circuits furnished to the Department of Commerce are used mostly for handling weather reports, considerable information also is transmitted relating to departure and arrival of planes and the positions of planes in flight. The Department of Commerce upon request will send over its teletypewriter system the license number of a plane, the station from which the plane is departing, its time of departure, and its destination, to stations along the route of the flight. Personnel of stations on this route knowing approximately the time due, then watch for the plane and record the actual time it passes so that other stations may be informed.

## TELETYPEWRITER CIRCUIT LAYOUT

Teletypewriter networks furnished by the Bell system for service along airways are composed of some 30 separate circuits. Circuit mileage of the longest is about 2,000 miles and of the shortest, 200 miles. The longer circuits generally connect 15 to 20 intermediate stations. Since airways naturally follow direct air lines the intermediate airway stations often are situated at points somewhat distant from main communication lines. (See Fig. 4.) At the larger airports such as Newark and Cleveland, local teletypewriter circuits also are provided to connect the Department of Commerce station with the offices of the various transport companies, the post office, and the weather bureau. Automatic transmission equipment is provided so that information received on 1 circuit can be retransmitted over 1 or more circuits as desired. Cable circuits, being less susceptible to interference and storm trouble than open wire circuits, where available have been used generally for establishing teletypewriter circuits furnished both to the Department of Commerce and to the transport companies. At present, over one-third of the mileage of these circuits is in cable. Facilities on alternate routes are available to be substituted for the regular circuit in the event circuit trouble develops.

### TELETYPEWRITER EQUIPMENT

Theory of teletypewriter operation has been described in other papers and hence will not be reviewed here. Tape and page type sending and receiving teletypewriters commonly used in this country are also used in airways service. Tape machines are particularly suited for this purpose since messages are usually short, and weather reports from the various stations can be conveniently posted by cutting and pasting the tape as desired. In addition to the ordinary sending and receiving machines, however, supplementary apparatus units may be used so that operators can work at maximum efficiency and the line circuit can be used to its maximum capacity. These units are the perforator, the tape transmitter, and the reperforator.

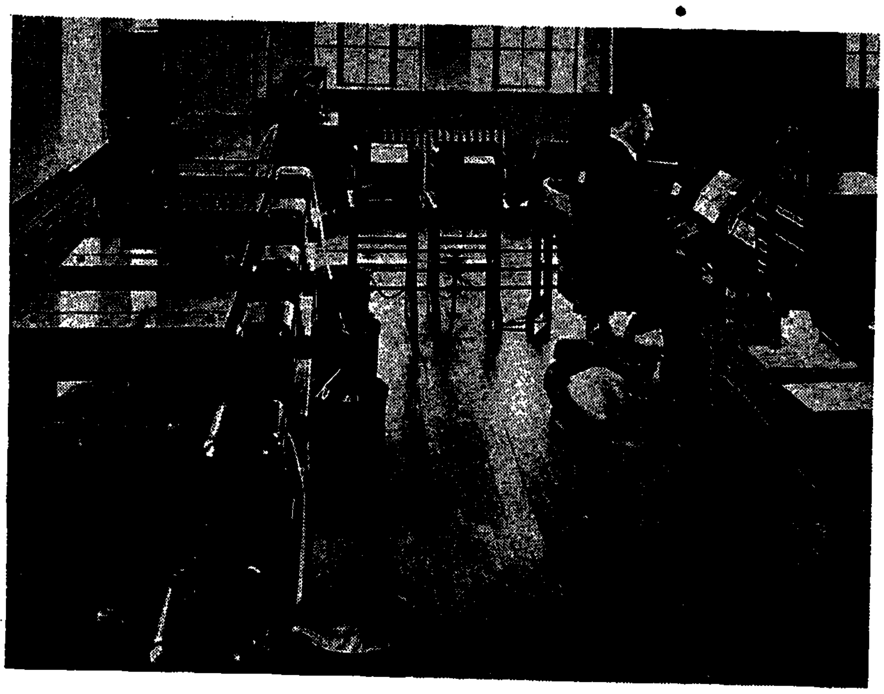

Fig. 5. A typical airport teletypewriter installation

The perforator is associated with a keyboard and perforates a tape with from 1 to 5 perforations for each key struck; the tape then is run through a tape transmitter which automatically sends electrical impulses to the circuit corresponding to the perforations in the tape and identical to those that would have been sent from the keyboard sending. Use of the perforator and tape transmitter permits the circuit to be operated at its maximum speed at all times and permits the operator to work in spurts and rest or do other work while the accumulated tape is running through the transmitter. Also the same tape can be run through several tape transmitters and thus can be used for sending the message over several circuits.

The reperforator is a receiving device which records the message on a perforated tape similar to that produced by a perforator unit. This permits storing a received message for immediate or subsequent retransmission to other circuits without retyping it.

The smaller teletypewriter stations of the Department of Commerce and those of the various transport companies generally are provided with one or two teletypewriters. At the larger stations of the Department of Commerce a special arrangement of equipment has been provided to permit efficient operation of the circuits from the standpoints of requiring the fewest operators and of obtaining rapid retransmission of messages received on 1 circuit to 1 or more of the other circuits, as required. A view of a typical installation is given in Fig. 5. The apparatus is mounted on tables specially designed for the purpose; these tables usually are arranged on the floor in the shape of a "U," the units facing inward so that the operators work inside the "U."

The arrangement of equipment generally permits 1 operator to attend all of the circuits. The teletypewriters are all installed in a fairly small space, which permits 1 man to observe the incoming messages, and to operate the control boards, to start and stop the proper transmitter, and to relay messages as required.

### RADIO INTERFERENCE

Establishment of teletypewriter stations along airways brought about the installation of teletypewriter equipment in the same room with, or in close proximity to, short-wave radio receivers; this introduced a problem in specific cases of radio interference caused by teletypewriter operation.

Remedial measures have been adopted effectively to reduce this interference and consist of the use of synchronous motors, rectifiers, and specially designed filters, together with the locating of the apparatus and wiring in such a way as to effect a minimum coupling between the teletypewriter and its associated loop, and the radio antenna system.

### CONCLUSION

History of air transportation in the past few years indicates that continued growth may be expected, particularly as hazards to flying are mitigated and as safety and dependability are recognized by the public. The government is continuing the extension of airways, weather reporting, and other services; and air transport companies are progressing in the development of transport business.

Fast and reliable communication service has proved to be the backbone of weather and position reporting, and has been a valuable aid in the handling of traffic and other matters relating to air transportation. Teletypewriter circuits used for land service have been found particularly suited to meeting the various requirements involving simultaneous communication with many stations at remote distances. Other wire communication services such as long distance telephone and commercial telegraph also have aided, particularly in reaching points not served by teletypewriter circuits. It is expected that wire communication service will continue to be used extensively in connection with air transportation, and will be of considerable aid in its future development.

# Stray Load Losses of a 55,000-Kva. Generator

Calorimeter tests on a 55,000-kva. hydro-electric generator show that the difference between stray load losses measured under load conditions and those measured under short-circuit conditions is slight. The method used by the authors is said to be applicable in general to all large units where an enclosed system of ventilation is used.

By

Hydro-Elec. Pwr. Comm. of Ontario, Toronto

**J. R. DUNBAR**
MEMBER A.I.E.E.
Canadian Westinghouse Co., Ltd., Hamilton, Ontario

IN ACCORDANCE with the A.I.E.E. standards, stray load losses of synchronous machines are determined with low excitation and with the machines short-circuited. There is still some question, however, as to whether this gives a true measure of the stray load losses under load conditions. In order to obtain a comparison between these losses on short circuit and under rated load, a series of thermal or calorimeter tests were made on one of the hydro-electric generators at the Queenston station of the Hydro-Electric Power Commission of Ontario, Canada. The machine tested is the last one installed and is rated as follows: 55,000 kva., 80 per cent power factor, 12,000 volts, three phase, 25 cycles, 187.5 r.p.m. The results showed but little difference between the losses measured on short circuit and those measured at rated load, the latter being slightly larger.

## METHOD OF TESTING

In general the method followed in making the tests was to operate the unit under several different conditions until the temperature of the cooling air, stator iron and stator copper became constant in each case; great care was taken to measure these quantities accurately, especially the temperature of cooling air. As the accuracy of these tests depends upon the accurate measurement of ingoing and outgoing air temperatures, high grade thermometers calibrated and graduated to 0.2 deg. cent. were used. For measuring the temperature of the outgoing air from the generator, ten of the thermometers were placed at the point where this air enters the cooler; ten thermometers also were used to ascertain the temperature of the air at the point where it leaves the cooler. Other thermometers were used to measure the temperature of the stator iron, the steel wall of the chamber enclosing the unit, the air outside this chamber, and the inlet air to the unit. To determine the temperature of the stator copper, thermocouples placed in the stator slots were used. Electrical readings of current, voltage, and power were taken with portable meters of good accuracy.

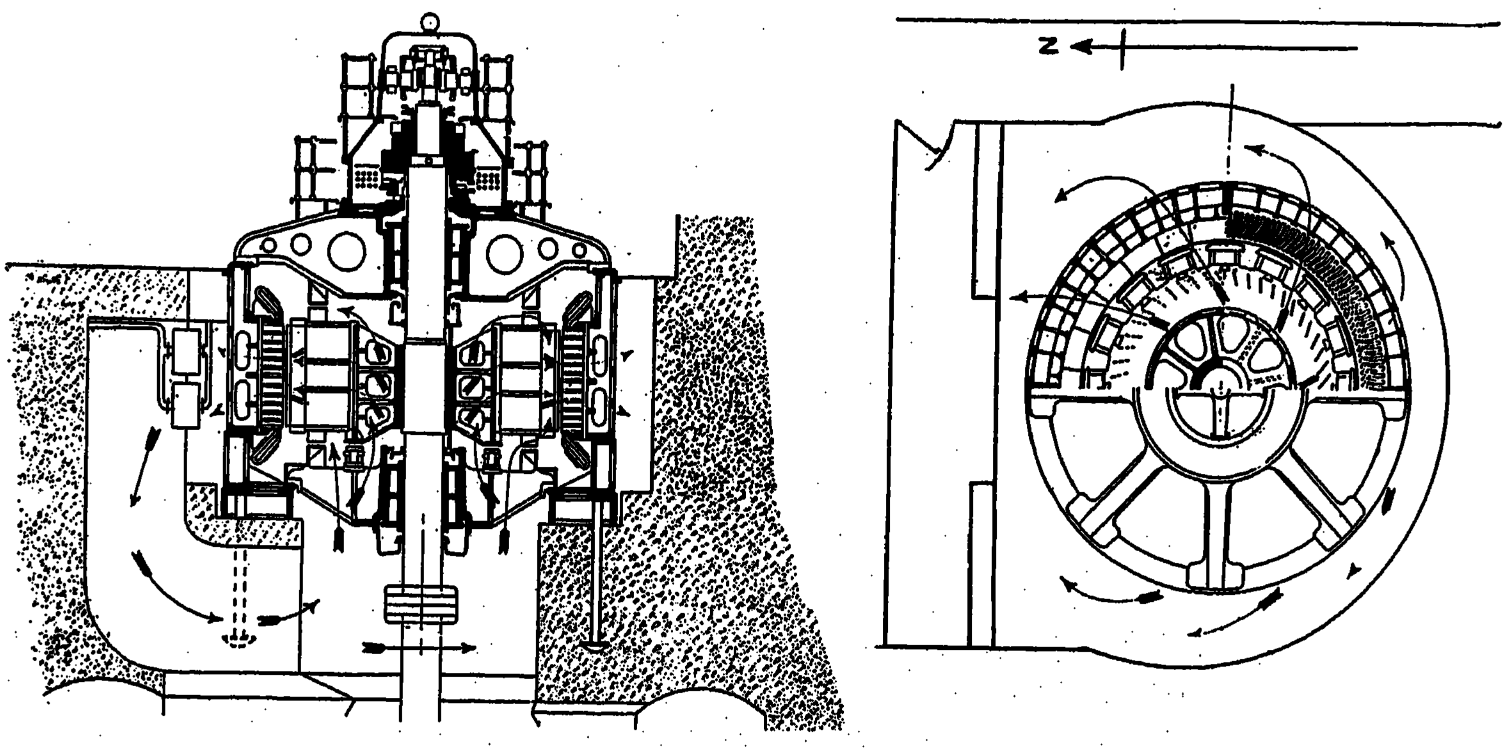

Fig. 1. Cross-section of 55,000-kva. generator for which stray load losses were determined; note completely closed ventilation system

Four different tests were made as outlined in the following paragraphs:

### Test No. 1—Windage Loss

For this test the unit was operated for 20$^1/_2$ hr. without excitation, starting with the machine hot. Temperature readings were taken during the first part of the run for a period of 5 hr.; at the end of

---

Based upon "Calorimeter Measurement of Stray-Load Losses of 55,000-Kva. Generator Having Enclosed System of Ventilation" (No. 31-126) presented at the A.I.E.E. Pacific Coast convention, Lake Tahoe, Calif., Aug. 25-28, 1931.

the run two additional readings were taken, these giving the temperature rise due to the windage loss.

### Test No. 2—Core Loss

For this test the unit was operated at synchronous speed without load, but with sufficient excitation to give 12 kv. at its terminals. This test extended over a period of 7 hr., temperature readings being taken throughout the run.

### Test No. 3—Short-Circuit Test

On this test the unit was operated at its rated current of 2,650 amperes under three-phase short circuit. In this test it was found difficult to hold the stator current constant on the unit, the exciter being a direct-connected shunt-wound machine; thus small variations in speed caused corresponding variations in the excitation and in the short-circuit current. No special arrangements were made to control the excitation of the unit; had this been done perhaps the accuracy of the test could have been increased a small degree.

### Test No. 4—Test at Rated Load

This test was made in two parts, (a) with a water rate of 500 gal. per min. through the coolers, and (b) with 400 gal. per min. through the coolers; both tests were made at approximately rated load. In order to complete the test in a minimum time the unit was operated for 8 hr. at approximately rated load, during which time no temperature readings were taken. The load then was set accurately as close to rated conditions as could be obtained and held, after which temperature readings were taken over a period of 3 hr. at $^1/_2$-hr. intervals. For the second portion of this test, the water rate was adjusted to 400 gal. per min., and temperature readings taken for an additional $4^1/_2$ hr. at $^1/_2$-hr. intervals.

## RESULTS AND CALCULATIONS

The results of the four tests are shown in Figs. 2 to 5, inclusive. Tests No. 2 and 4 are of particular interest. For Test No. 2, the results are quite consistent and indicate that the temperatures of the unit and the temperature rise of the air can be found accurately; however, the test must be continued long enough to allow the temperatures of all parts of the machine to reach a constant value. It may be noted that the temperature of ingoing air to the unit rises along with the temperature of the unit itself; also that the air, iron, and copper temperatures arrive at a constant condition at the same time.

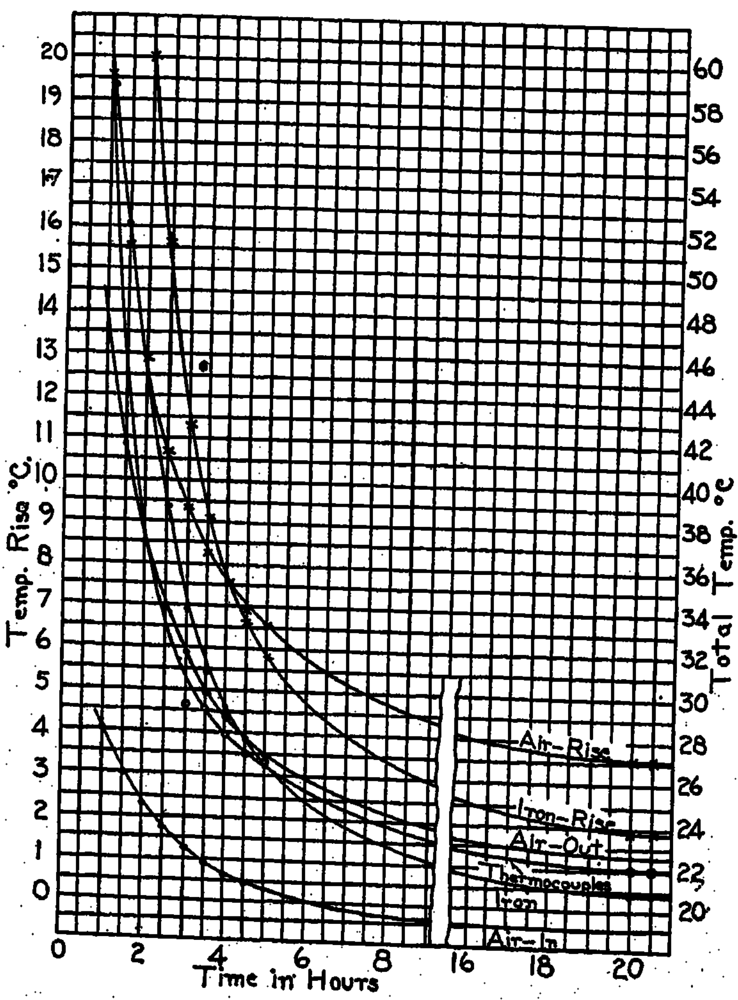

Fig. 2. Cooling curves for windage loss test (No. 1)

Test No. 4 indicates the accuracy with which the temperature measurements were made, and the effect of changing the water rate through the coolers. It may be noted from Fig. 5 that immediately following the adjustment of water rate, changes in temperature occurred which, although not great, were quite definite. The curves show also that a period of $4^1/_2$ hr. was required to bring the unit back to new constant temperatures differing from the previous ones by approximately $1^1/_2$ deg. The temperature rise of the air and of the iron, however, were the same values for both water rates.

Stray load losses are determined by the difference between the total losses as calculated from the temperature rise of the air and the known losses. The method of determining these losses from the test results is as follows: Temperature rise due to windage only is given by the results of Test No. 1, while Test No. 2 gives the rise due to windage and core loss; the difference between these two values obviously gives the rise due to core loss only. Since the core loss is known from other tests, a constant $K$ may be calculated giving the kilowatt loss per degree rise. With the aid of this constant, the loss for any other operating condition may be determined directly from the air rise.

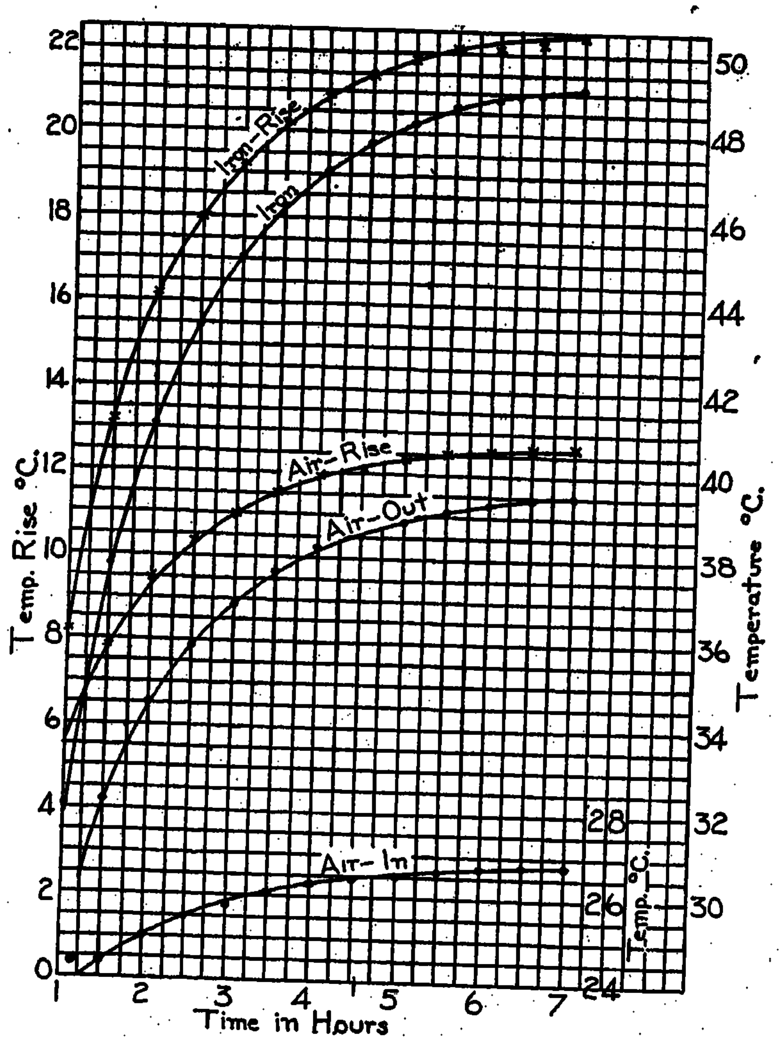

Fig. 3. Heating curves for core loss and windage test (No. 2)

| | |
|---|---|
| Terminal potential.................... | 12,000 volts |
| Field current.......................... | 314 amperes |
| Collector ring potential................ | 98 volts |

These calculations involve the following temperature assumption: In an enclosed ventilating system where heat is being generated at a constant rate and the air is being cooled in coolers using a constant flow of water, the loss converted into heat is proportional to the temperature rise of the air, after all conditions have become constant. It is evident that the crux of the method is that all conditions must be constant. Among other things this requires that the humidity and barometric pressure must not change during any series of tests. If the pressure were to drop appreciably, the constant $K$ would be affected, and it would be necessary to repeat the *windage* and the *windage and core loss* tests, in order to obtain reliable results; also, a constant $K$, determined under certain atmospheric conditions, obviously cannot be used with the results of tests under different atmospheric conditions.

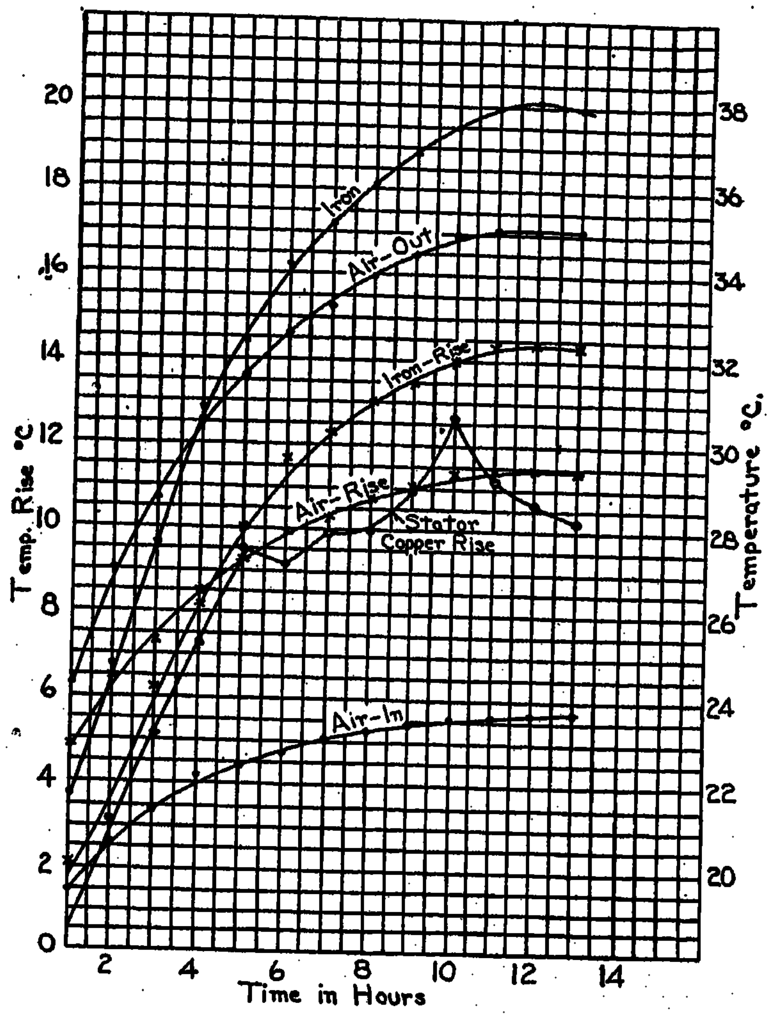

**Fig. 4. Heating curves for short circuit tests (No. 3)**

| | |
|---|---|
| Armature current | 2,650 amperes |
| Field current | 320 amperes |
| Collector ring potential | 98 volts |

Losses thus computed from these tests are shown in Table I. As a check on these results, losses computed from the heat absorbed by the cooling water are shown also in Table I. These figures are in remarkably close agreement when it is considered that the thermometers used in the cooling water were read to the nearest half degree only.

As a further refinement an attempt was made during the various tests to determine the amount of heat lost from the shell surrounding the generator. Temperatures of the shell and of the surrounding air were determined and the radiation loss calculated; these values are shown also in Table I as are recalculated values of the various losses taking into account these radiation losses. These latter calculations indicate that the radiation loss makes but a very small difference in the losses measured in this test, probably less than the experimental error associated with the test itself.

Stray power losses determined from the short-

circuit (No. 3) and rated-load (No. 4) tests are shown for comparison in Table II; these are shown with and without provision for radiation losses.

## CONCLUSIONS

Results of these tests indicate that for this particular type of unit, the stray load losses under short circuit and at rated load are approximately equal. The stray load losses are about 50 per cent of the stator copper loss at rated load. The results indicate also that if sufficient care is taken in measuring the temperatures, the stray load losses can be determined with fair accuracy on large units when an enclosed system of ventilation is used. The great drawback appears to be the time necessary to make a complete series of tests, although it is possible that a compromise test over a short period of time could be made and the final temperature rise of the air determined by calculation. The results obtained by Laffoon and Calvert (A.I.E.E. TRANS., v. 46, 1927, p. 84–98) from calorimeter tests on turbine-generators agree with the results of these tests in that the stray load losses under load conditions are shown to be slightly higher than under short-circuit conditions. A logical conclusion seems to be then that if an accurate determination of the losses is required, a test under load conditions is justified; but for most purposes, a test under short-circuit conditions seems to be sufficient.

---

# Characteristics of a Mercury Vapor Tube

**Results of an investigation of the grid and plate currents in a grid-controlled mercury-vapor tube show that the direction of grid current in these tubes depends not only upon the instantaneous polarity of the grid, but also upon the magnitude of both the grid voltage and the plate current. It is shown also that inverse plate current flows whenever grid current is flowing during the negative half cycle of plate voltage.**

INCREASING use of grid-controlled mercury-vapor tubes for regulation, control, and rectification, makes desirable a study of certain characteristics of these valves which, judging from the literature available, have not as yet received the attention they deserve. The behavior of plate and grid currents, especially the latter, in some instances may inhibit the proper functioning of the tube and cause it to fail to play its proper rôle in the circuit.

One of the few investigators who has published his findings on the subject is Nottingham (*Journal*, Franklin Institute, v. 212, 1931, p. 271) who studied the grid and plate currents of these tubes chiefly under conditions prior to discharge. He found, as might be expected, that before the cathode-to-anode discharge takes place, the tube behaved as a gaseous triode. From preliminary experiments it became evident that some interesting studies were possible by investigating the plate and grid currents under various conditions of discharge. Accordingly, a series of tests was conducted using a typical mercury vapor tube of this type; the results point to the following conclusions:

1. The instantaneous direction of current flow in the grid circuit of a grid-controlled mercury-vapor tube depends not only upon the instantaneous polarity of the grid with respect to the cathode, but also upon the magnitude of the effective grid potential and upon the plate current.

2. The grid current may consist of positive loops only, of positive and negative loops of varying areas or equal areas, and of negative loops only, depending upon (*a*) the magnitude of the effective grid potential which determines whether or not the grid is able to repel positive ions when it is instantaneously positive, and electrons when it is instantaneously negative; and (*b*) the magnitude of the plate current which determines the degree of ionization present.

3. A d'Arsonval meter cannot be used in the grid circuit to determine the value of grid current, since the grid current wave generally has both positive and negative loops; in the extreme case where these loops are equal, such a meter would indicate zero current, although there might be an alternating current of considerable magnitude flowing.

4. When the grid voltage lags the plate voltage, the positions of the positive and negative loops of grid current may be transposed by merely varying the grid voltage.

5. An inverse plate current of the order of milliamperes always is present when grid current is flowing concurrent with the negative half cycle of plate voltage. When the grid current during the negative half cycle of plate voltage is zero, the lag of deionization of the mercury vapor allows some ionization to be present when the plate voltage changes to negative, thereby yielding a minimum, but not zero, value of inverse plate current.

6. With constant average grid current, the inverse plate current varies approximately sinusoidally with the angular displacement between the grid and plate voltages.

7. Formation of the positive ion sheath that envelops the grid and causes cathode-to-anode discharge is inhibited at low alternating grid voltages, by electrons having sufficient kinetic energy to enter the grid when it is at an instantaneous negative potential. For consistent operation the grid voltage employed to initiate discharge should be several times the critical voltage of the tube.

---

Written especially for ELECTRICAL ENGINEERING: *Not published in pamphlet form.*

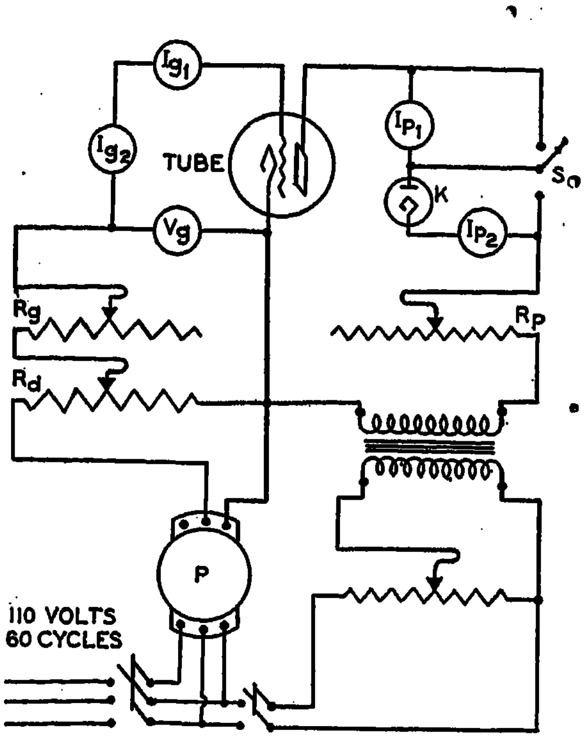

**Fig. 1. Circuit diagram for determining characteristics of grid-controlled mercury-vapor tubes**

## Test Procedure

The tube used for this investigation was a General Electric type FG-29, air-cooled thyratron, intended for use as a controlled rectifier. The cathode of this tube is of the uni-potential coated type, the heater of which requires a current of 12 amperes; this was supplied from a special filament transformer. The tube is designed for a maximum forward and inverse potential of 3,500 volts, and a maximum average plate current of 12.5 amperes.

The circuit employed in the tests is shown in Fig. 1. The plate of the tube was energized from a 110/1,100-volt transformer. Voltage for the grid, variable in magnitude and phase, was obtained by means of a potential divider $R_d$ which in turn was connected to one phase of a three-phase phase-shifter $P$. All tests were carried out at a frequency of 60 cycles and, unless otherwise stated, at an r.m.s. plate potential of 1,100 volts.

For measuring average values of the grid and plate currents d'Arsonval meters $I_{g1}$ and $I_{p1}$ were used; the effective value of the grid current was measured by a heater-thermocouple instrument $I_{g2}$. A dynamometer voltmeter $V_g$ was connected directly between grid and cathode to measure the grid voltage. Inverse plate currents were measured by a d'Arsonval instrument $I_{p2}$. By throwing switch $S$ to the upper position, the positive loop of plate current was blocked by tube $K$, a two-element high-vacuum rectifier. Resistances of the grid and plate circuits were varied by variable resistors $R_g$ and $R_p$, respectively.

In the oscillograms reproduced* it was thought more expedient to give the average and effective values of grid currents in lieu of placing current scales on the oscillograph traces themselves. Using a three-element oscillograph, two photographs for each condition were taken in order to include the four variables, grid voltage ($V_g$), grid current ($I_g$), plate voltage ($V_p$), and plate current ($I_p$); all four quantities have been shown together, however, by inking the wave of $V_p$ on the oscillograms showing the other three values.

## Grid Voltage in Phase With Plate Voltage

When the grid voltage is in phase with the plate voltage and is sufficiently high to repel electrons when the grid is instantaneously negative, the grid current wave consists of positive loops extending over the positive half cycle of the grid voltage wave. Under these conditions the grid current follows the shape that would be expected from a two-electrode mercury-vapor valve, but its wave is modified considerably with very low grid potentials. The oscillogram in Fig. 2 shows that with $V_g = 5$ volts (r.m.s.) the grid current is completely negative and exhibits two peaks. During the first portion of the positive half cycle of grid voltage, positive ions were able to enter the grid and thereby give rise to negative grid current; as the grid voltage reached its maximum positive value, the grid was able to repel the positive ions and attract electrons the net effect of which was to reduce the negative grid current to zero; however, as the grid voltage decreased from its maximum positive value, positive electrons again were able to enter the grid, thereby setting up another negative peak of grid current.

An increase of 1 volt in $V_g$ removes the second negative loop of $I_g$ shown in Fig. 2, and causes this portion of $I_g$ to become positive; this is demonstrated in Fig. 3, the plate current and grid resistance being

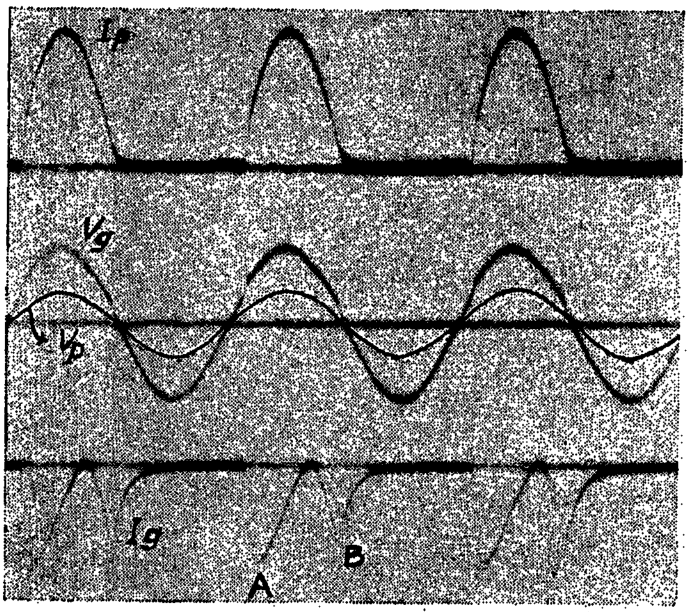

Fig. 2 (left)

$V_g$ = 5 volts (r.m.s.)
$I_g$ = 100 milliamperes (avg.)
$R_g$ = 100 ohms
$V_p$ = 1,100 volts (r.m.s.)
$I_p$ = 1.2 amperes (avg.)

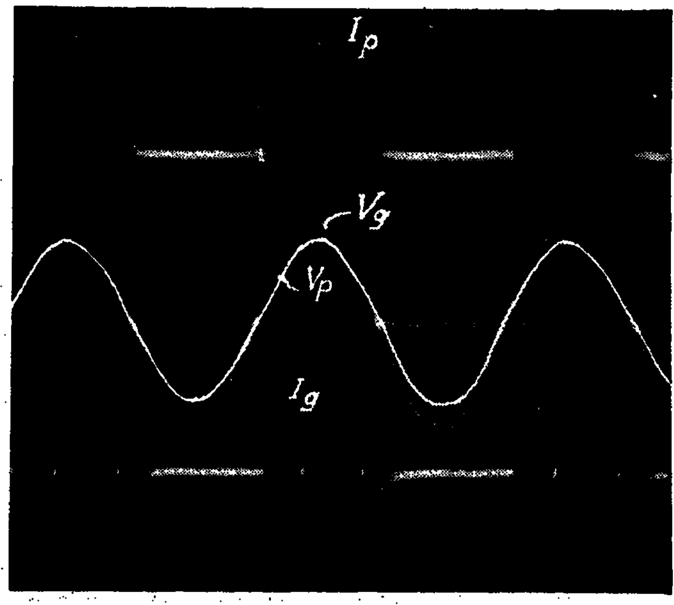

Fig. 3 (right)

$V_g$ = 6 volts (r.m.s.)
$I_g$ = 0 (avg.)
$I_g$ = 3 milliamperes (r.m.s.)
$R_g$ = 100 ohms
$V_p$ = 1,100 volts (r.m.s.)
$I_p$ = 1.2 amperes (avg.)

**Fig. 2 (left) and 3 (right). Voltage and current relations with plate and grid voltages in phase**

maintained at the same values as in Fig. 2. It may be observed that the increase in $V_g$ from 5 to 6 volts enabled the grid to attract enough electrons, as $V_g$ traversed its maximum values in its positive half cycle, to set up a positive loop of $I_g$, the area of which was equal to the area of the negative loop; thus the average grid current was zero, but the effective value was 3 milliamperes. As the grid voltage is increased beyond 6 volts, the negative loop of grid current decreases and the positive loop increases, until finally the grid current consists solely of positive loops.

From the foregoing it would be expected that if the average value of grid current were plotted against grid voltage, the curve first should have negative values, then reverse itself and later become positive. That this actually takes place may be seen from Fig. 4, where such curves have been drawn for three values of plate current with the plate and grid voltages in phase. From 0 to 3.75 volts the grid currents were too small to show on this plot, but their behavior in this region has been described by Nottingham (*loc. cit.*). The cathode-to-anode discharge took place at 3.75 volts. At this point, ionization caused by the flow of plate current furnished positive ions of sufficient velocity to enter the grid and make the areas of the negative loops exceed the area of the positive loop, as in Fig. 2.

For a given grid voltage the average value of the negative grid current depends upon the degree of ionization, i. e., upon the plate current; hence the 5-ampere curve shows the greatest negative value of average grid current, and the 10 milliampere curve, the smallest. As the grid voltage is increased, the positive loop of grid current also increases and the negative loops decrease, causing the curves to attain a negative maximum and return to zero. All three curves cross the zero axis in the region where the grid voltage equals from 6.5 to 7 volts; this is the region where the positive loop of grid current is equal to the negative loop as in Fig. 3. The positive loop of grid current increases also with ionization; hence above the zero axis the three curves lie above each other in the order of magnitude of their corresponding plate currents because the positive loop of grid current increases with plate current as well as with grid voltage; the negative loops finally disappear. Thus the curves cross as they intersect the zero axis and reverse in order.

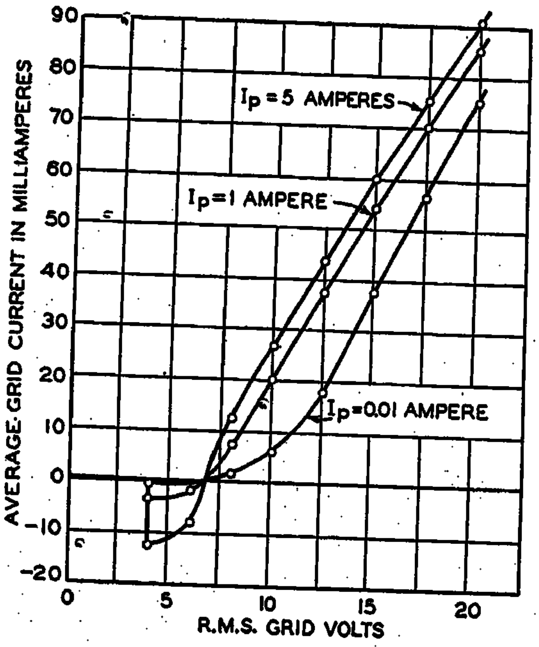

**Fig. 4. Grid voltage-current relations with grid and plate voltages in phase**

$V_p$ = 1,100 volts
$R_g$ = 100 ohms

## Grid Voltage Leading Plate Voltage

When the grid voltage leads the plate voltage, the grid is positive before the tube begins to discharge. When the grid voltage becomes negative, the tube is discharging, positive ions are available, and hence the wave of grid current becomes negative. In Fig. 5 the grid voltage is shown leading the plate voltage by 90 deg. Grid current starts flowing when the grid becomes positive, then rises to a maximum, and falls to zero with the grid voltage. When the grid voltage becomes negative, the tube is still discharging and hence still generating positive ions. These positive ions enter the negative grid forming a negative loop of grid current which increases with the instantaneous value of grid voltage; this increase continues until the plate current is reduced to zero, when the source of positive ions disappears. At this point the negative grid current falls rapidly to zero, and remains so until the grid voltage becomes positive again in the following cycle. Thus, while the first half of the positive loop of grid current occurs before the tube discharges, the entire negative loop occurs while the plate current is flowing. From

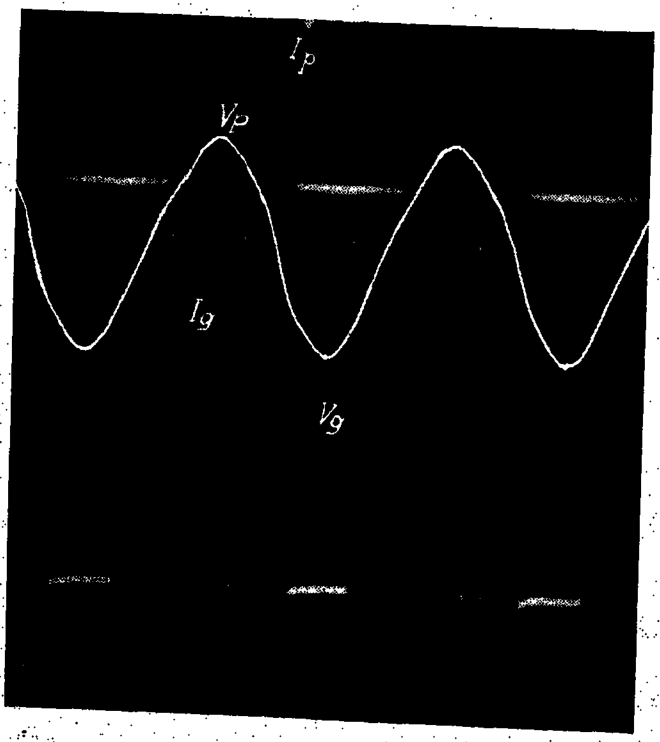

**Fig. 5. (Left) Voltage and current relations with the grid voltage leading the plate voltage by 90 deg.**

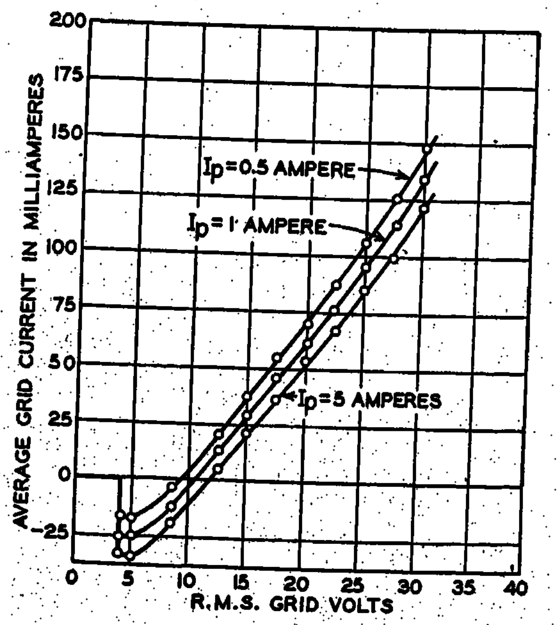
$V_g$ = 40 volts (r.m.s.)
$I_g$ = 275 milliamperes (avg.)
$I_g$ = 600 milliamperes (r.m.s.)
$R_g$ = 100 ohms
$V_p$ = 1,100 volts (r.m.s.)
$I_p$ = 4 amperes (avg.)

**Fig. 6. (Right) Grid voltage-current relations with the grid voltage leading the plate voltage by 90 deg.**

$V_p$ = 1,100 volts, $R_g$ = 100 ohms



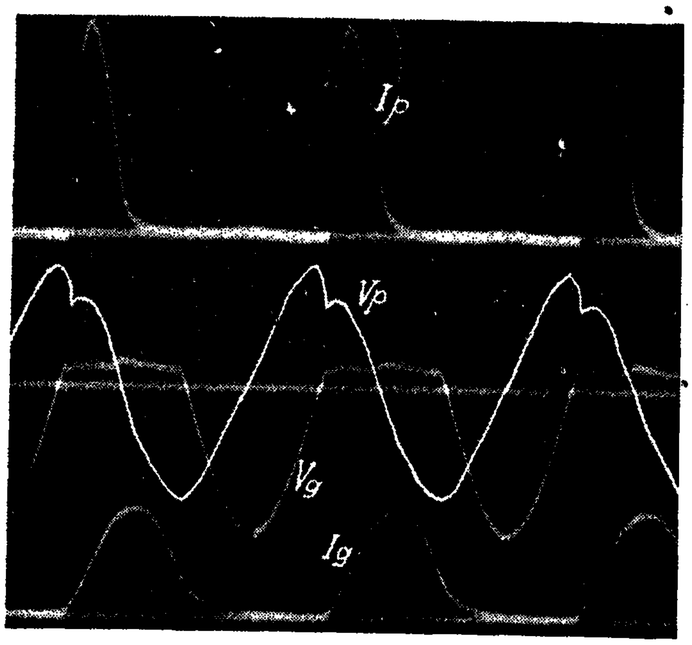


Fig. 7 (left)

$V_g$ = 30 volts (r.m.s.)
$I_g$ = 165 milliamperes (avg.)
$I_g$ = 220 milliamperes (r.m.s.)
$R_g$ = 100 ohms
$V_p$ = 1,100 volts (r.m.s.)
$I_p$ = 1.5 amperes (avg.)

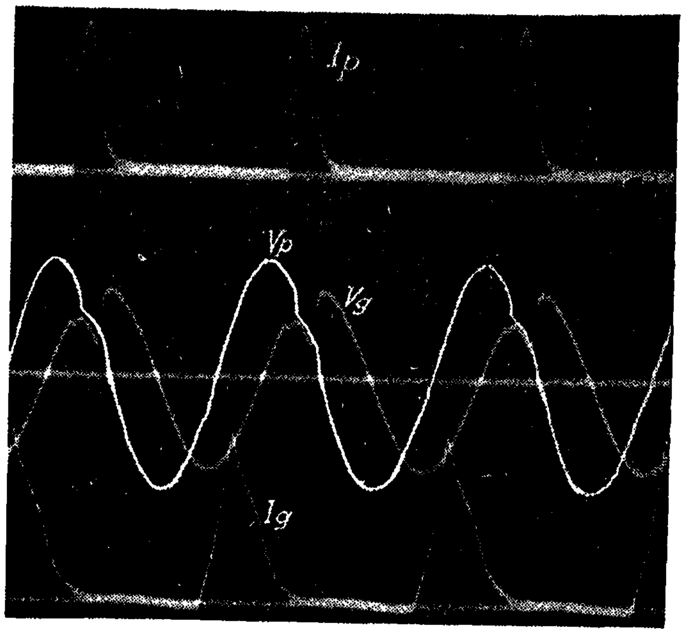

Fig. 8 (right)

$V_g$ = 6 volts (r.m.s.)
$I_g$ = 6 milliamperes (avg.)
$R_g$ = 100 ohms
$V_p$ = 1,100 volts (r.m.s.)
$I_p$ = 1.2 amperes (avg.)

**Fig. 7 (left) and 8 (right). Voltage and current relations with the grid voltage lagging the plate voltage by 90 deg.**

this it would be expected that with a decrease in grid voltage the negative loop would grow faster than the positive loop.

If the grid voltage be reduced to small values, the negative loop of grid current decreases more slowly than the positive loop, and the average grid current becomes negative. Variation of the average grid current with grid voltage, with the grid voltage leading the plate voltage by 90 deg., is shown in Fig. 6. Shapes of the curves are similar to those obtained with grid and plate voltages in phase, with the exception that the curves do not cross each other and reverse their order as they intersect the zero axis (see Fig. 4). From 0 to 3.75 volts the grid currents were too small to plot, as in Fig. 4. At 3.75 volts, the tube discharged and the grid currents became negative, the negative values for a fixed grid voltage increasing with the plate current. This is due to the negative loop of grid current increasing with the increase in ionization afforded by the increase in plate current. As the grid voltage increases, the curves attain their negative maxima and return to zero in the interval where the grid voltage equals from 9 to 12 volts. Above the zero axis, the curves for the lower plate currents assume higher positions, i. e., for a fixed grid voltage the average value of grid current decreases with plate current; the loops of negative grid current increase with plate current. At the same time, a large portion of the positive grid current flow occurs before the tube discharges. The result of this is that with increase in plate current for a given grid voltage the negative portion of grid current grows more rapidly than the positive portion, and the average grid current decreases with an increase in plate current. For this reason the curves do not reverse their order as they cross the zero axis.

## GRID VOLTAGE LAGGING PLATE VOLTAGE

Behavior of the grid current when the grid voltage lags the plate voltage by 90 deg. is shown in the two oscillograms reproduced as Figs. 7 and 8. In Fig. 7, $V_g$ was maintained at 30 volts. During the negative loop of grid voltage, no plate current flows because no positive ions are present and the grid current is zero. When the grid becomes positive, a positive grid current begins to flow increasing to a maximum value, then decreasing gradually to zero after the grid voltage has become zero. The discharge has ceased since the plate voltage has become negative; thus there is no source of positive ions for the negative grid and accordingly the grid current remains at zero until the grid becomes positive in the next cycle.

If the grid voltage be reduced to a much lower value than in Fig. 7, the positive loop of grid current will be found to shift its position from the second quarter cycle (counting from the instant when the plate voltage becomes positive) to the first quarter cycle. An oscillogram for this condition is presented in Fig. 8, where $V_g$ was reduced to 6 volts. Comparing Figs. 7 and 8, the positive loop of grid current apparently has shifted from the quarter-cycle during which the tube discharges, to the quarter-cycle of positive plate voltage during which there is no discharge. In Fig. 8, although the grid voltage is low, no electrons enter the grid by virtue of their velocities during the fourth quarter-cycle when the grid is negative, because of the negative potential of the plate. During the first quarter-cycle, however, the plate voltage is positive and electrons coming from the cathode are able to impinge upon the grid although the grid is at a negative potential with respect to the cathode; thus a positive loop of grid current is formed during the first quarter-cycle. The total current produced by electron emission from the cathode entering the grid is small compared with the ionization available for producing grid currents when the tube is discharging. Accordingly, the magnitude of the positive loop of grid current for a grid potential of 5 volts is small compared with that for a grid potential of 30 volts, the average grid currents in the two cases being 5 and 165 milliamperes, respectively.

Referring to Fig. 8 again, when the grid voltage becomes positive and discharge begins, the resultant ionization produces positive ions of sufficient velocity to enter the grid, although the grid is at a low positive potential and is receiving electrons from the filament. The net result is that the grid current is reduced to zero and remains so until the plate voltage becomes positive in the following cycle. If the voltage of the grid was lowered still further, the grid current in the second quarter cycle would not only be reduced to zero, but would be depressed to a negative value by the positive ions generated by the plate current.

## Inverse Plate Current

Whenever the grid voltage either lags or leads the plate voltage, grid current flows during part of the negative half cycle of the plate voltage; when the grid voltage leads the plate voltage, the initial portion of the grid current flow occurs when the plate voltage is negative; when the grid voltage lags the plate voltage, grid current is flowing when the plate voltage changes from positive to negative. Whenever grid current is flowing, positive ions are available because of ionization of the mercury vapor. Hence whenever grid current is concurrent with negative plate voltage a negative loop of plate current should be present. The oscillograms presented thus far show no negative loops of plate current because of the disparity in magnitudes between the positive loops and the negative loops, the latter of which have their origin in the comparatively small amount of ionization afforded by the grid current.

When the phase displacement between the plate and grid voltages is 175 deg., a positive loop of grid current flows when the plate voltage is negative; this condition is illustrated in Fig. 9 where the average value of plate current was reduced to 13 milliamperes by plate circuit resistance to bring out the negative loop more prominently. With fixed plate voltage, the magnitude of inverse plate current depends upon the magnitude of grid current flowing when the plate is negative. When the potential of the grid is sufficiently high to prevent electrons from impinging upon the grid when it is negative, and likewise to prevent positive ions from entering the grid when it is positive, the grid current follows the grid voltage with a certain lag. From this it follows that with a constant average grid current, maintained by adjustment of grid voltage, the variation of inverse plate current with phase displacement between grid and plate voltages should be approximately sinusoidal. In Fig. 10 are plotted values of negative plate current against angular displacement between grid and plate voltages, for three constant values of average grid current. These curves follow quite closely the form $A + B \cos(\theta - \alpha)$ where $\theta$ is the angular displacement between the grid and plate voltages, $\alpha$ is the angular displacement between the grid voltage and current, and $A$ and $B$ are constants. Sinusoidal variations computed on the basis of maximum values of the observed currents coincide with the experimental curves obtained, except for a short section of the curve for an average grid current of 0.2 ampere; that portion of the computed curve which deviates is shown by a broken line. Data for these curves were taken by throwing switch $S$ in Fig. 1 to the upper position, thereby blocking the positive loops of plate current by tube $K$ and reading the average values of inverse current on milliammeter $I_{pi}$. The plate potential was maintained at 1,100 volts (r.m.s.) and the plate circuit resistance when the inverse plate current was flowing was the plate resistance of tube $K$, a type KM-1 kenotron.

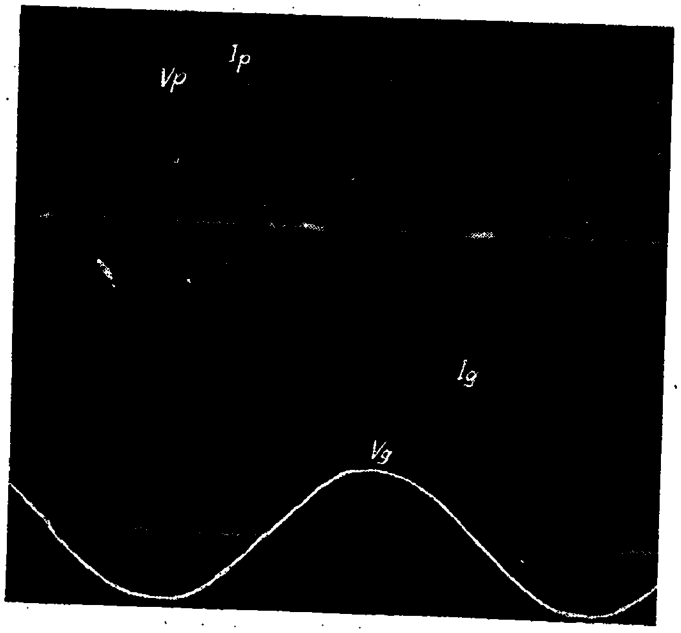

Fig. 9. Voltage and current relations with the grid voltage leading the plate voltage by 175 deg. Note inverse plate current

$V_g$ = 60 volts (r.m.s.)
$V_p$ = 1,100 volts (r.m.s.)
$I_g$ = 790 milliamperes (avg.)
$I_p$ = 17 milliamperes (avg.)
$R_g$ = 50 ohms

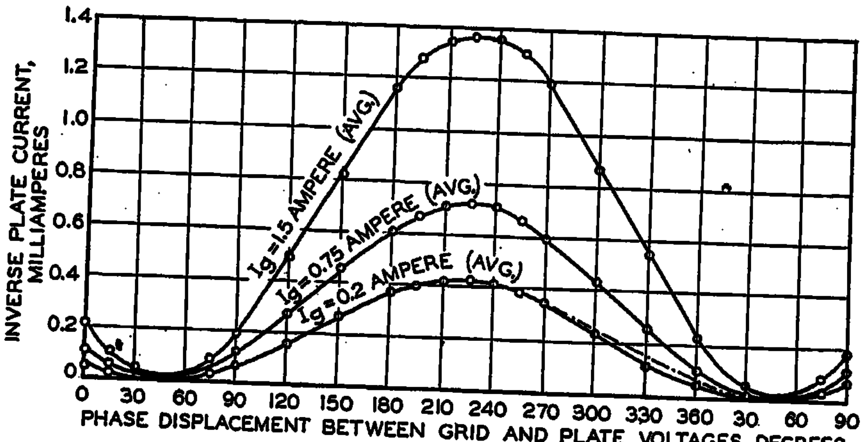

Fig. 10. Inverse plate current as a function of phase displacement between grid and plate voltages

The grid current in the inverse current tests lagged the grid voltage by approximately 40 deg.; from this it would be expected that the inverse plate current would be at its maximum value when the positive loop of grid current coincides with the negative loop of plate voltage, that is, at 180 deg. + 40 deg. This is seen to be the case in Fig. 10. In the same way the minimum value of inverse plate current is shifted from the 0-deg. point by the same angular displacement. There is no null value of inverse plate current because when the positive loop of grid current is contained wholly within the positive loop of plate voltage, the plate becomes negative before deionization is complete; hence there is a small source of positive ions which yields a minimum but not zero value of negative plate current at that point.

From the foregoing it may be seen that no matter what the phase displacement between the grid and plate voltages may be, an inverse plate current always is present. Its minimum value is determined by the quantity of positive ions remaining, due to lag in deionization, when the plate potential reverses; its maximum value is determined by the magnitude of grid current flowing when the plate voltage is negative.

Two tubes of the same type were studied and only slight variations of magnitude in the phenomena described were observed. Because the number of tubes was limited to two, the characteristics presented are not set forth as average characteristics of grid-controlled mercury-vapor tubes, but merely as typical of this particular type of tube.

# Insulator Performance Studied by Flashover Tests

**Many factors affect the flashover characteristics of porcelain insulators; these characteristics in turn have a direct bearing upon insulator design and upon the choice of proper insulation for any particular purpose. In the following group of three articles by representatives of three of the leading insulator manufacturers, results of investigations made in this field by these manufacturers are given. In the past, many of the data for comparable insulators from different sources seemed conflicting. In these articles, however, reasonably careful study will reveal many points of agreement, when the results are reduced to a comparable basis. The first two articles deal with the effect of various factors on insulator sparkover characteristics; the third article deals with the flashover characteristics of suspension insulators, and also contains data relating to the cost and selection of economical suspension insulator assemblies.**

## I—Insulator Arcovers Versus Size and Humidity

By
H. A. FREY
ASSOCIATE A.I.E.E.

K. A. HAWLEY
MEMBER A.I.E.E.

Both of the Locke Insulator Corp., Baltimore, Md.

DATA covering the electrical characteristics of comparable insulators as received from different sources frequently are conflicting. In an attempt to clarify some aspects of this controversial subject, a study has been made to establish rules whereby such characteristics can be estimated from the dimensions of the insulators with a reasonable degree of certainty. Variations in the arcover potential of dry insulators due to the influence of humidity changes also are considered and approximate correction ratios given.

Conclusions of the study are based upon an extensive series of tests made in the high voltage laboratory of the Locke Insulator Corporation at Baltimore, Md. Throughout the tests all voltage measurements were made as prescribed in the A.I.E.E. Standards. All tests were made at a frequency of 60 cycles.

SUSPENSION INSULATORS

Tests were made on suspension insulators of both the cemented and Hewlett types, with unit spacings of from $4^3/_4$ to 7 in. and with diameters ranging from 10 to 12 in. It was found that within these dimension limits the flashover voltages of all insulators when dry fell upon one curve when plotted against actual arcing distance, the shortest air path between

Based upon "Normal Frequency Arcover Values of Insulators as Affected by Size and Humidity" (No. 32-62) presented at the A.I.E.E. Great Lakes District meeting, Milwaukee, Wis., March 14-16, 1932.

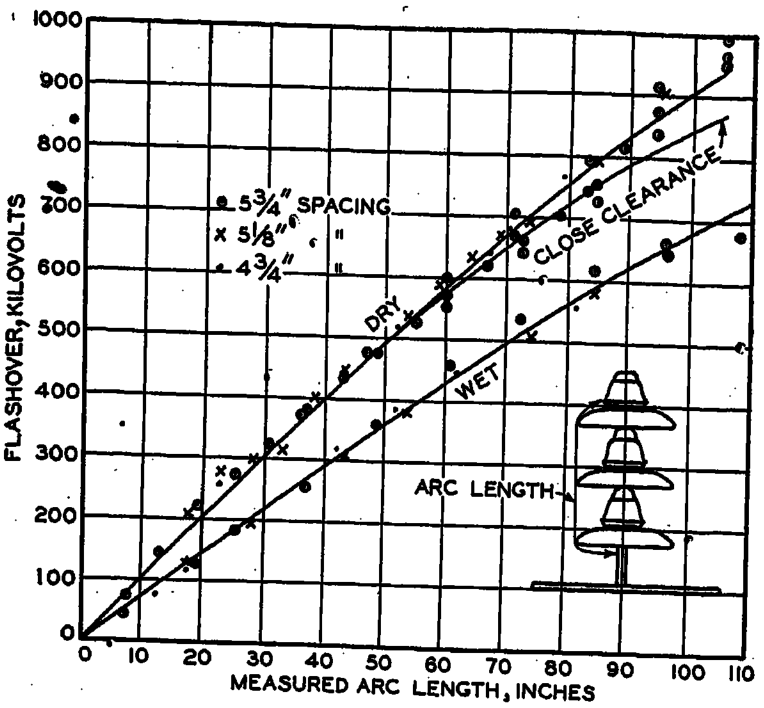

**Fig. 1. (Left) Flashover characteristics of 10-in. standard-strength suspension insulators**

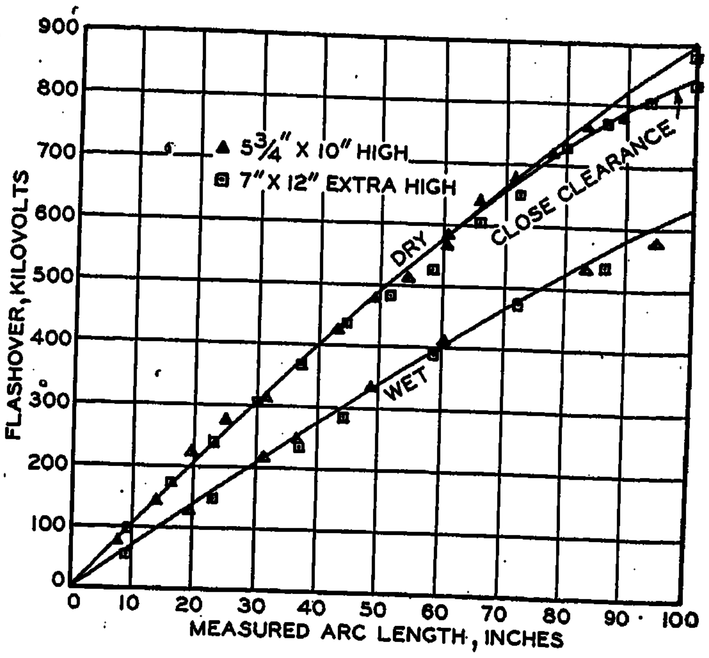
**Fig. 2. (Right) Flashover characteristics of high-strength insulators**



electrodes. Flashover for voltages for wet insulators when so plotted showed some variation depending upon the design of the insulator. The curves of Figs. 1 and 2 show the dry and wet values for cemented type insulators plotted against actual arcing distance. Flashover voltages for dry insulators are affected by the proximity of grounded objects. This is shown by the double graph at the upper end of the dry curves, the upper graph being obtained with clearances at least twice the length of the insulator string.

For design purposes it is most usual to plot flashover voltages for wet insulators as a function of the wet striking distance or the summation of the air gap distances beneath the insulator, assuming that the wetted surfaces above are short-circuited out by the water film. A satisfactory check is so obtained as shown by Fig. 3. Expected arcover potentials for dry and wet suspension insulator assemblies are given in Figs. 4 and 5, plotted as a function of the number of units in the string, and calculated from Figs. 1 and 2.

Standard- and high-strength cemented insulators were tested also in the anchor position at an angle of about 10 deg. from the horizontal. Arcover voltages obtained for both dry and wet conditions are shown in Figs. 4 and 5 in comparison with corresponding values for the vertical assemblies. The "dry" arcover values are materially lower for the horizontal than for the vertical position; "wet" values, however, are much higher for the horizontal than for the vertical. This is because when the entire surface of the insulator is uniformly wetted, a better voltage division between insulator units is obtained with the resultant higher voltage necessary to cause breakdown. The "wet" values for the horizontal strings are actually equal to, and in some cases with long strings, higher than the "dry" values for the same position.

Most of the tests in the horizontal were made without a jumper loop under the string or a conductor at right angles to it. Insulators in the horizontal position with the conductor at right angles showed dry arcover potentials materially higher than without it, yet not equal to the values obtained for the vertical suspension insulators.

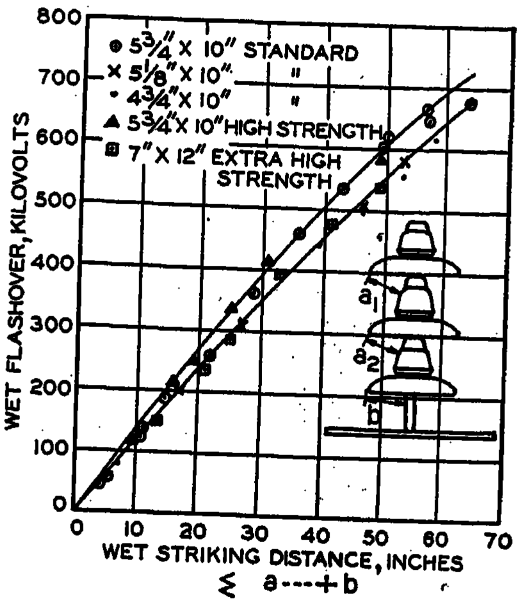


**Fig. 3. Flashover characteristics of all-cemented suspension insulators when wet**

## PIN INSULATORS

Standard pin insulators show fairly uniform arcover voltages in proportion to the distance between electrodes as shown in Fig. 6. The small contact area of tie wires upon the porcelain causes heavy dielectric flux concentration on the tie wires, with resultant active corona streamer formation at voltages near arcover. Because of the erratic action of these streamers, observed data show the least uniformity of any of the types of insulator tested.

It is interesting to note that more consistent comparisons of data for wet pin insulators are obtained on the basis of *total* striking distance rather than *wet* striking distance. The low sparkover voltages for the small one-piece insulators when wet are due to the large proportion of wetted surface to total striking distance.

## OUTDOOR APPARATUS INSULATORS

Outdoor apparatus insulators are pin types modified by adding cemented-on caps for attachments. In comparison with pin types these insulators show less variation between individual observations. This is brought about by the greater contact area of the cap, which causes less flux concentration and less corona streamer formation at voltages below flashover.

In Fig. 7 are shown flashover voltages of single and multiple unit insulators when both dry and wet; in both cases the results are plotted against actual arcing distance. As is shown, however, data for the wet condition are far more consistent when plotted against wet striking distance.

## Equipment Bushings

Performance of solid porcelain equipment bushings (not oil filled) is shown in Fig. 8 for ratings from 7.5 to 69 kv. The field established about the bushing determines its arcover potential when dry. In tests of this nature it is important that the conductor be in place inside the insulator as it will be in service, since much higher values are obtained without it. When the bushings are wet the arcover potentials are the breakdown voltages for the water film on the surfaces; for the larger bushings the values are higher when the insulator is wet than when dry.

## Humidity Effects

The effect of humidity upon the dry arcover voltages of insulators may be compared on several different bases as follows:

1. By a comparison of flashover values on the basis of per cent humidity. This is not satisfactory, for it alone does not account for the total quantity of water in the air.
2. By a comparison on the basis of absolute humidity or mass of water per unit of air volume. This method may be satisfactory, but does not account for the molecular activity of the water.
3. By a comparison of flashover on the basis of water vapor pressure in some convenient units such as inches of mercury in the barometric method. This accounts not only for the number of water molecules present, but for their velocity as well.

Throughout the common range of temperature the numerical difference between vapor pressure (expressed in manometric inches of mercury) and absolute humidity (expressed in grains per cubic foot) is so slight as to make no practical difference as to which is used as the basis. Water vapor pressure as the standard is recommended by the A.I.E.E. Standards (41-100); hence all observations in this portion of the investigation have been compared upon this basis.

Effects of humidity upon the dry flashover of standard suspension insulators are shown in Fig. 9. By plotting on semi-logarithmic paper equal ordinate distances give equal percentage variations. Thus it is easy to compare percentage corrections for different strings and percentage variations from the average of individual observations. The slope of all these average graphs is practically the same. When referred to 100 per cent at the standard water vapor pressure, 0.608 in. of mercury the correction at 0.2 in. of mercury is −8 per cent; the correction factor, therefore,

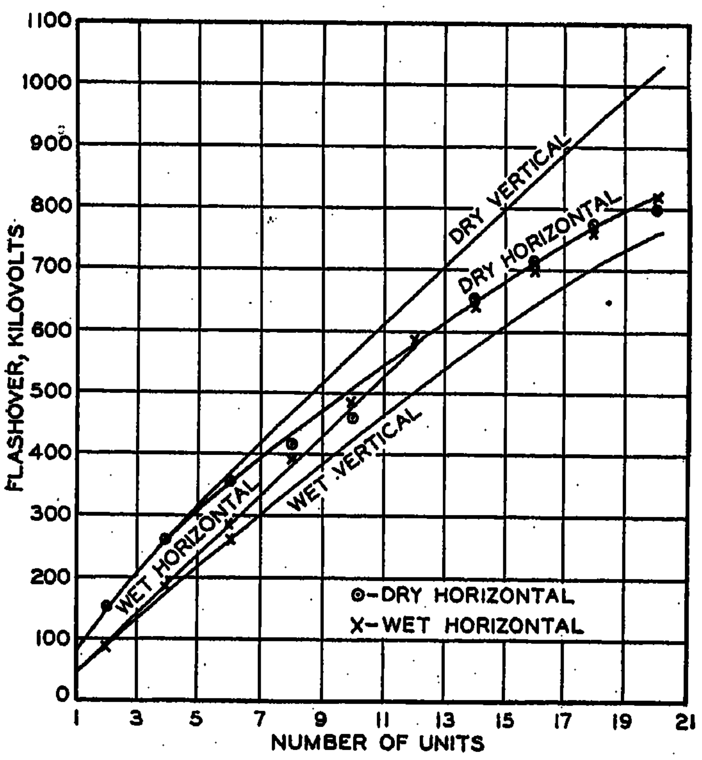

**Fig. 4. (Left) Flashover characteristics of insulator assemblies made up of 10-in. standard-strength units, spaced 5³/₄ in. apart**

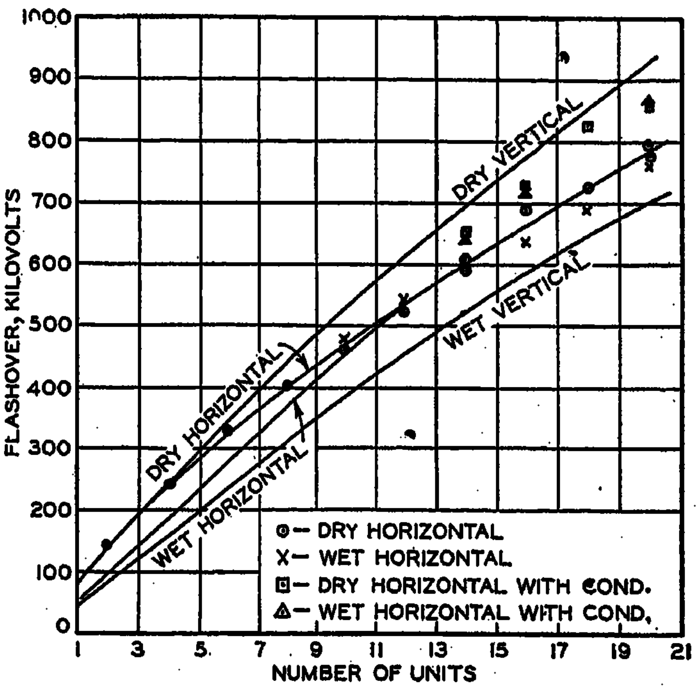

**Fig. 5. (Right) Flashover characteristics of suspension insulator assemblies made up of 10-in. standard-strength units, spaced 5¹/₈ in.**

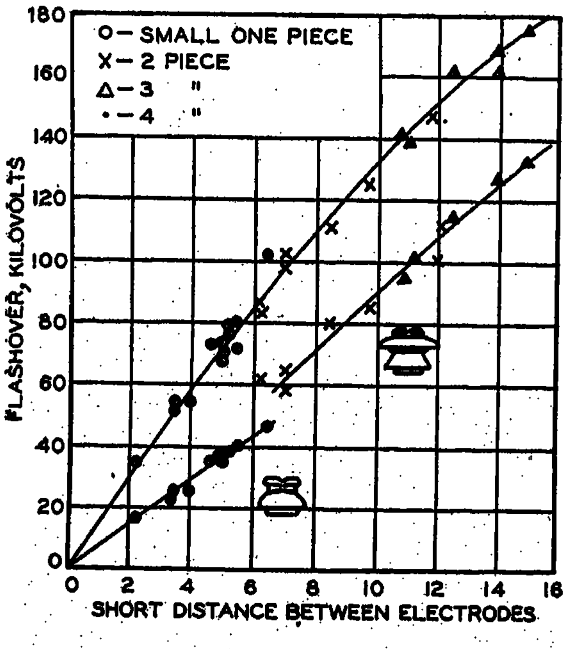

**Fig. 6. (Left) Flashover characteristics of pin insulators**

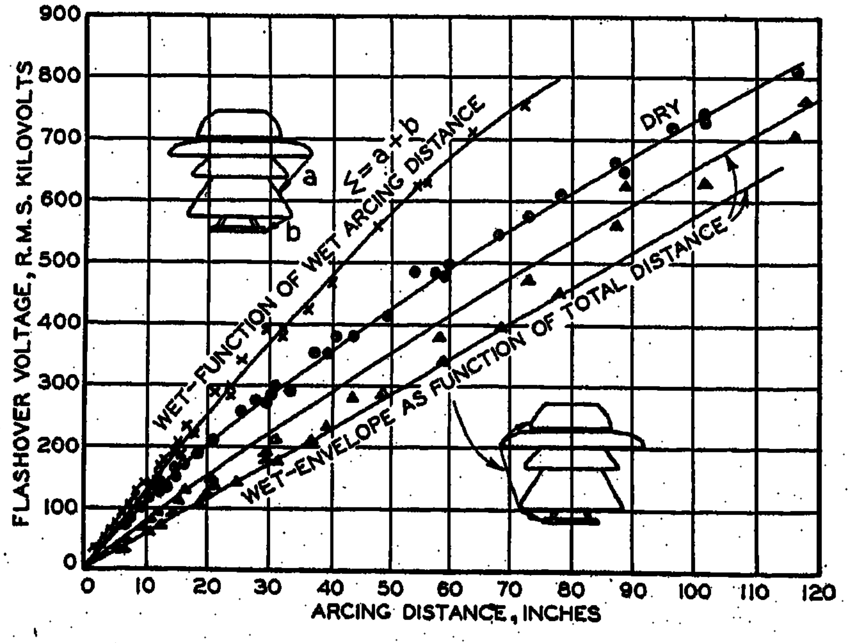

**Fig. 7. (Right) Flashover characteristics of outdoor apparatus insulators**

is approximately 2 per cent for each 0.1 in. of mercury variation in water vapor pressure.

As may be seen from Fig. 9, the points of observation would be inclosed within an envelope of plus and minus 5 per cent from the curve of averages. It follows, therefore, that even with the correction for humidity a variation of plus or minus 5 per cent in flashover values of suspension insulators must be expected.

Effects of humidity on flashovers of typical pin insulators are shown in Fig. 10. Only one insulator of each type was tested; thus the variations shown are not due to manufacturing variations in different insulators. The individual observations may be seen to lie within an envelope of plus or minus 6 per cent; the broadest variation of any type of insulator tested. The variation in flashover of all insulators between vapor pressures of 0.2 and 0.608 in. of mercury is about 12 per cent. Frequently in testing at standard temperature with a relative humidity above 65 per cent, erratic performance and marked fall in flashover voltage was observed. A typical example of this is shown for the 27-kv. insulator. Such behavior is believed to be due to the formation of an invisible water film upon the surface of the insulator at these higher humidities.

Tests were made also to determine the effect of humidity upon typical outdoor apparatus insulators. Compared with the pin types these insulators showed much more stable performance; this is due to absence of corona streamers as already discussed. Variation from the average curve is not over plus or minus 5 per cent, and the correction for humidity is 8 per cent between vapor pressures of 0.2 and 0.608 in. of mercury, the same as for suspension insulators, but less than for pin types.

Performance of porcelain equipment bushings with varying humidity also was investigated. The humidity correction for these bushings was found to be the same as for all others except the pin types.

### EFFECT OF SURFACE CONDITIONS

In an effort to determine how the above rules for insulator flashover might be affected by surface conditions, representative insulators were exposed for a period of several months above the smoke boxes of a battery of beehive kilns. At the expiration of this period the surfaces of these insulators were thoroughly covered with a dirt deposit consisting largely of carbonaceous material mixed with a certain amount of clay dust and ordinary floor dirt. Due to the baking action of the heat from the kilns the coating was rather hard. Other insulators of exactly the same type were thoroughly coated with a salt crust by spraying them with a concentrated salt solution and allowing them to dry.

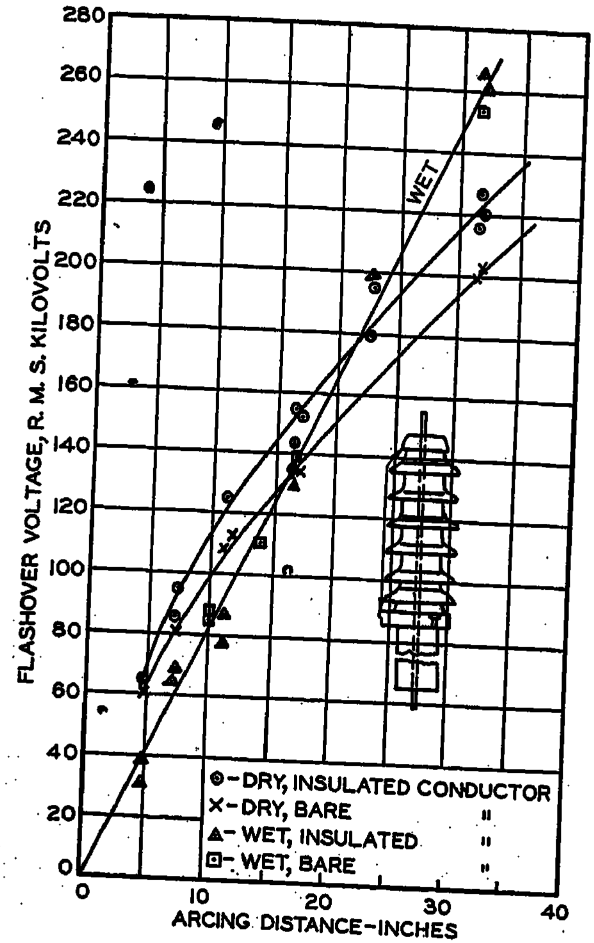

Fig. 8 (Left) Flashover characteristics of solid type equipment insulator bushings

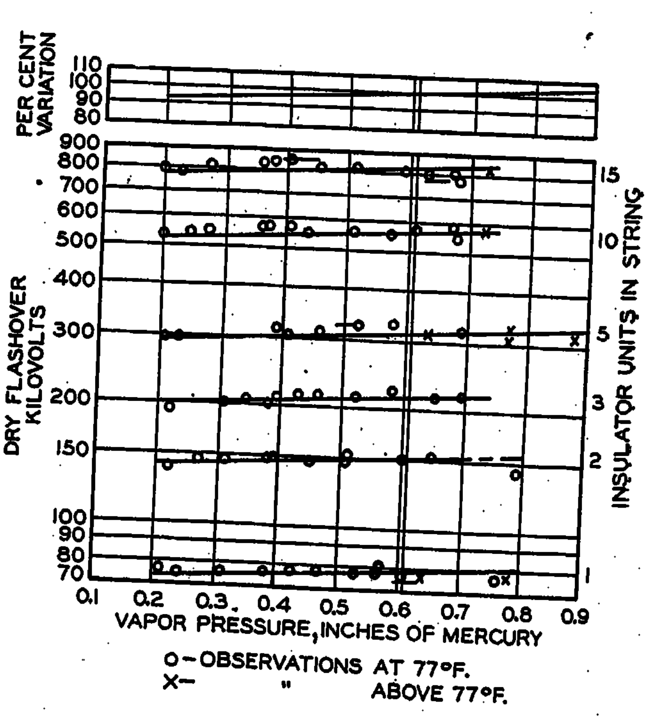

Fig. 9. (Right) Effect of humidity on the flashover voltage of standard suspension insulators

**Table I—Flashover Voltages of Dirty and Salt-Coated Insulators**

| Condition | 35-kv. Pin Type | 44-kv. Pin Type | One Unit 5³/₄ × 10 In. Disk | Three Units 5³/₄ × 10 In. Disk |
|---|---|---|---|---|
| Dry, clean, 65% Humidity | 120 | 135 | 77 | 204 |
| Dry, salt-coated, 79% Humidity | 97 | 97 | 34 | |
| Dry, salt-coated, 65% Humidity | 112 | 114 | 75 | |
| Dry, dirty, 65% Humidity | 116 | 128 | 69 | 205 |
| Wet, clean | — | 95 | 48 | |
| Wet, salt-coated | 34–63 | 52–80 | 27–44 | |
| Wet, dirty | — | 67–74 | 36–53 | |
| In steam fog, clean | 56 | 74.5 | 33 | 139 |
| In steam fog, salt-coated | 24 | 34 | 23 | |
| In steam fog, dirty | 48 | 68 | 32.5 | 114 |

These insulators then were flashed over, first clean and dry, then salt-coated and dry, and finally dirt-coated and dry. Tests were repeated with the insulators in a steam chamber filled with steam at a temperature of approximately 100 deg. fahr. to simulate fog conditions. Finally some of the insulators were tested as specified by the A.I.E.E. standard wet flashover test. Some typical results are shown in Table I.

It may be noted that there is but little reduction in the dry flashover voltage of the insulators when dirty. Dry tests on the salt-coated insulators were made at

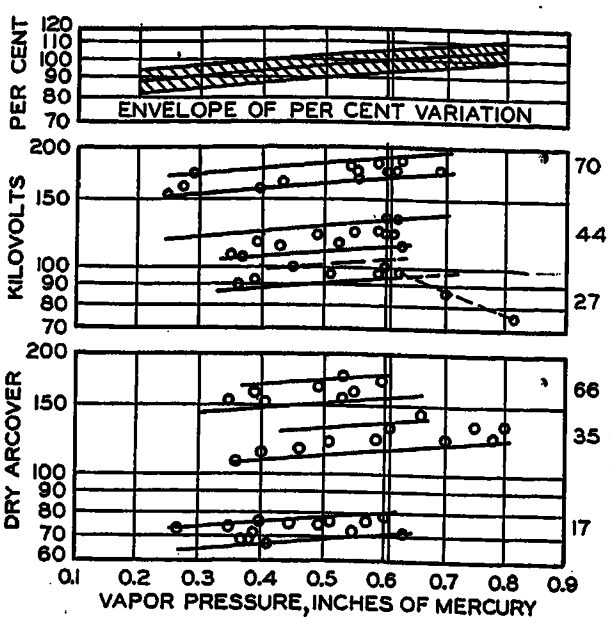

**Fig. 10. (Left) Effect of humidity on the flashover voltage of pin insulators**

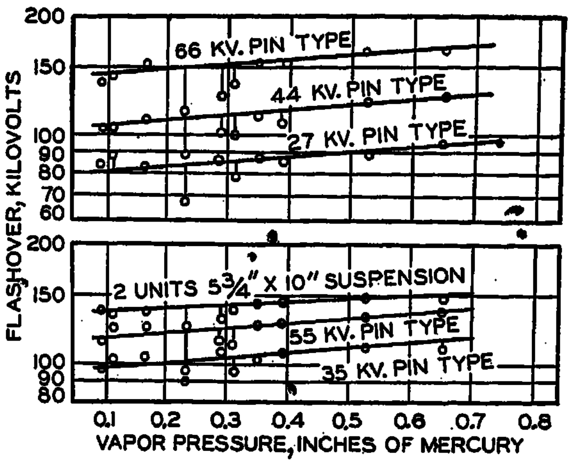
**Fig. 11. (Right) Flashover voltages of dirty insulators as a function of humidity**



two humidity conditions. The first group of tests yielding the higher values in the tabulation was made at approximately 77 deg. fahr. dry bulb temperature, 65 per cent relative humidity. The second group of tests made at approximately the same temperature and at 79 per cent relative humidity gave flashover values materially lower, probably due to the absorption of moisture by the salt. At the lower humidity the dry flashover voltage of the salted insulators is nearly the same as that of clean insulators.

**Table II—General Summary of Test Data**

| Insulator Type | Dry Flashover Kv. per In. of Arcing Distance | Wet Flashover Kv. per In. of Arcing Distance | Wet Flashover Kv. per In. of Wet Striking Distance | Humidity Correction per 0.1 In. Mercury, Water and Vapor Pressure |
|---|---|---|---|---|
| Suspension (up to 100-in. string length) | | | | |
| Standard cemented | 10.5 to 9 | 7 to 6.8 | ——— | 2% |
| High-strength cemented | 10.5 to 9 | 7 to 6.3 | 14 to 10.6 | |
| Hewlett flat disk | 10.5 to 9 | 7.5 | | |
| Hewlett fish tail | 10.5 to 9 | 6.5 | | |
| Pin Types | | | | |
| Small one piece | 14 | 7.0 | ——— | 3% |
| Multi-part | 14 to 11.4 | 8.9 | Erratic | 3% |
| Apparatus insulators | 11 to 7.3 | 8 to 5.7<br>Erratic | 13 to 10.4 | 2% |
| Equipment Bushings | | | | |
| Solid type with insulated conductor | 13.6 to 6.75 | 8.3 | ——— | 2% |
| Solid type with bare conductor | 12.4 to 6.1 | 8.3 | | |

Where two figures are given above the first applies to small insulators, and the second to the largest with fairly uniform steps between, except where noted as erratic.

When subjected to artificial fog the salt-coated insulators showed in most cases a decided decline in flashover voltage; the flashover voltage of dirt-coated insulators under fog conditions also was decreased but not so severely.

In a further effort to study the effect of surface conditions on the flashover of insulators, other insulators were hung on the roof of the laboratory for a period of one year, each insulator being flashed over approximately once a month. Since the laboratory is situated in a heavy industrial district the insulators were subjected to soft coal smoke and industrial gas fumes. All flashover measurements were made at a time when the insulators apparently were thoroughly dry. These tests were made, of course, at such humidity and temperature as happened to exist at the time. Results are plotted in Fig. 11. It may be noted that the curves are identical with those of Figs. 9 and 10.

Certain points on each of the curves of Fig. 11 fall materially below the average. The low values did not occur toward the end of the exposure period as would be expected if they were due to an increase in dirt accumulation with time. In fact the reading taken at the end of the year lies on the curve very nicely at 0.659 in. of mercury vapor pressure. The group of low values recorded at 0.235 in. vapor pressure occurred after the third month of exposure. The low values shown at 0.292 and 0.314 in. vapor pressure occurred, respectively, after seven months and two months. It is believed that in these cases the dirt film on the surface was slightly moistened. Since most of the tests were made in the morning it is quite possible that in these cases there was still a small amount of invisible dew remaining on the surface of the insulators.

Agreement between the curves in Figs. 9 and 10 and those in Fig. 11 is interesting especially in view of the temperature variation in the latter tests. The highest temperature recorded during the time of exposure was 82 deg. fahr., occurring at the time of the first observation after zero time of exposure; the lowest temperature recorded was 27 deg. fahr., occurring at the test after the fourth month of exposure.

## CONCLUSIONS

Relations found between arcing distance and insulator flashover and between humidity and insulator flashover are indicated in the foregoing curves and have been summarized in Table II;

the following conclusions seem justified:

1. At high relative humidities there is in some cases a scattering of test results with points falling below the humidity curves. This is believed to be due to the precipitation of a fine moisture film on the surface of the insulators.
2. Deviation of individual flashover voltages from the average are not fully explained by humidity variations alone. After correction for humidity has been made, a variation of about plus or minus 5 per cent remains in some cases.
3. The same humidity corrections are applicable to dry, dirty insulators as to clean insulators.
4. Dry dirt on the insulator surfaces only slightly lowers the flashover voltage, but a small amount of moisture greatly reduces the flashover voltages of dirty insulators, particularly if the dirt is of a saline nature.
5. At high relative humidities the flashover voltages of salt-coated insulators is materially reduced due to absorption of water by the salt.

# II—Factors Affecting Insulator Sparkover

By
W. L. LLOYD, JR.
MEMBER A.I.E.E.

General Elec. Co.,
Pittsfield, Mass.

WHILE the mechanical properties and strength of the various parts entering into the design of a modern transmission system are quite well known, the electrical characteristics of the various parts often are not so definitely understood. This is true particularly of the electrical properties of the insulating parts, including the line and station insulation and bushings used in the station equipment. In this article are presented data on the sparkover strength of the various parts used for the insulation of modern high voltage transmission systems. Results are given of tests made to determine how insulator sparkover is affected by various factors.

The more common factors having a direct influence on the sparkover voltage of insulators are: temperature, barometric pressure, humidity, smoke, steam, dew, fog, rain, and surface dirt and moisture. Effects of temperature and barometric pressure on the 60-cycle sparkover voltage were determined some years ago. On the basis of these earlier studies it is generally sufficiently accurate to assume that the change in sparkover voltage is directly proportional to the change in air density; this holds true for both 60-cycle and lightning or impulse voltages. All sparkover voltages in these tests have been corrected to an air density of unity, using correction factors determined in the earlier tests.[1,2]

Regarding the effects of humidity but little data heretofore have been published.[3,4] Tests made in different laboratories, under identical conditions in so far as A.I.E.E. specifications are concerned, often fail to produce identical results. For the most part these differences can be attributed to the effect of humidity or water vapor in the atmosphere in which the tests are made. Effects of some of the remaining factors enumerated in the preceding paragraph have been recognized for some time but in most cases specific quantitative data have been lacking. Accordingly, some heretofore unpublished data on the effects of these factors are presented in this article.

## HUMIDITY

When the humidity for a given sparkover test has been specified, common practise has been to express it in terms of relative humidity. No confusion would result by such a procedure if all sparkover tests were made at approximately the same temperature. The effect of humidity then would be indicated by plotting sparkover voltage as a function of relative humidity. Sparkover tests, however, sometimes are made over a wide range of temperature, but the results so plotted are of little value in comparing the humidity effect and in finding an agreement in the sparkover voltage at some given humidity. A single curve of sparkover voltage as a function of relative humidity for different temperature cannot be drawn; the effect can be shown only by drawing a group or family of curves, each individual curve pertaining to one particular temperature.

Since humidity generally has been expressed in relative values, it has been difficult to interpret its true effect; hence different laboratories have found it hard to agree upon the sparkover voltage at any given humidity. When reduced to an absolute-humidity basis, however, the tests made by different laboratories show strikingly similar results; this is revealed by the curves shown in Fig. 12. These tests have been made with four different sets of testing equipment in four laboratories. Three of the laboratories employed artificial humidity control; the fourth was an outdoor laboratory in Pittsfield, Mass., under natural humidity conditions occurring from day to day and season to season. All these tests were conducted in accordance with A.I.E.E. Standard No. 41. The dip in these curves beyond a density of about 9 grains per cu. ft. will be discussed later.

Effects of humidity on the sparkover voltage of standard-duty suspension insulators of different sizes and having different spacings are shown in Figs. 12, 13, and 14; Fig. 15 shows the effect of humidity on certain sizes of pedestal insulators and a large pin insulator.

The sphere-gap appears to be practically independent of humidity effects. This is not true of the needle-gap, however, as may be seen from Fig. 16. These data are in agreement with previous data on the effect of humidity on the sparkover of spheres and needles.[4,5] In Fig. 17 the data of Fig. 16 are rearranged to show sparkover voltage as a function of gap spacing; the standard needle-gap curve also is indicated.

It may be noted that several of the humidity-sparkover curves for insulators indicate a lowering of

the voltage sparkover for absolute humidities above approximately 9 or 10 grains per cu. ft. That this is an effect of surface moisture or condensation on the porcelain surfaces of water vapor from the atmosphere at these high absolute (and generally relative) humidities, and not an effect in the air-gap, is indicated by the absence of this effect in the curves for the needle-gap and sphere-gap, particularly the

former. This conclusion is indicated also by the data in Fig. 18 where tests were made on chilled and slightly heated insulators. It is indicated also by the difficulty commonly experienced when tests on insulators at high humidities show a constantly rising sparkover voltage in repeated tests. The surface moisture results in low sparkover voltage in the initial test; repeated sparkovers remove this surface moisture and the insulator gradually acquires the higher sparkover voltage resulting from the high humidity. Frequently this increase continues for 25 or more tests before the sparkover voltage becomes constant at the upper value.

## SMOKE, ATMOSPHERIC MOISTURE, AND SURFACE DIRT AND MOISTURE

In this portion of the investigation 60-cycle sparkover tests were made on 10-in. standard duty suspension insulators with $5^3/_4$-in. spacing in atmospheres of smoke, steam, dew, fog, rain, and on insulators coated with surface dirt and moisture. Results of these tests are shown in Figs. 19, 20, and 21.

Results of tests made under dry, light rain, and heavy rain conditions are shown in Fig. 19; these are for insulators in a vertical position. Rain tests with the insulators in a horizontal position indicate no lowering of the sparkover potentials with the rain directed either at right angles to the string, or either from or toward the line end at an angle of 45 deg. to the string, and at 45 deg. from the vertical in all cases. On a horizontal string, rain improves the voltage distribution along the string sufficiently to raise the rain sparkover potentials to that of the dry. In the vertical position the drip along the vertical axis overbalances this effect and actually lowers the sparkover potentials. In Fig. 20 are shown the variations of sparkover voltage with resistivity of the water and rate of precipitation for clean insulators and bushings.

The effects of dirt and moisture on the 60-cycle sparkover are shown in Fig. 21. For these tests the insulators were exposed for a long time to the steam and smoke from a locomotive until they were coated with a carbon deposit perhaps $^1/_{32}$ to $^1/_{16}$ in. in thickness. From Fig. 21 the following observations may be made.

1. When dry the deposited dirt had practically no effect upon the insulator sparkover.
2. Sparkover potentials for the dirty insulators with top surface moistened were but slightly lower than for clean insulators with top and bottom surfaces moistened.
3. Clean and dirty insulators had approximately the same sparkover potentials under artificial rain conditions of 0.2 in. per min. at 45 deg. from vertical, as specified by A.I.E.E. tests. This was presumably because some washing of the insulators took place.
4. Dirty insulators with both top and bottom surfaces moistened (by light spraying) had low sparkover voltages.
5. Under conditions just indicated in item 4, combined with an atmosphere of heavy steam and locomotive smoke surrounding the string, the sparkover voltages were the lowest of any measured in these tests.

## LIGHTNING SPARKOVER

Results of tests to determine the effect of humidity upon lightning sparkover of different insulators are given in Fig. 22. It may be noted that the variation in sparkover potential between a density of 3 and 10 grains per cu. ft. was found to be approximately plus and minus 10 per cent for the sizes tested. This is of the same order as with 60-cycle voltages. Similar tests made on various gaps show corresponding results. Dew, fog, rain, and surface moisture were found to have but little effect upon the lightning sparkover of insulators, but in general their effect decreases as the length of the wave decreases.

Tests on wood poles and crossarms, with and without porcelain insulators mounted on the arms, exhibit lightning sparkover characteristics similar to those of porcelain insulators alone. Wood poles, crossarms, and guy insulator sticks of different cross-sectional areas have a lightning sparkover potential of approximately 175 kv. per ft. of length, whether the wood be dry or wet with clean water or saturated with salt water and brine.[6] The probable reason for this is that water is a fairly good insulator for impulse voltages as compared with air in which these materials ordinarily are tested.

# III—Designs and Economics of Suspension Insulator Strings

By
J. J. TOROK
ASSOCIATE A.I.E.E.

C. G. ARCHIBALD
NON-MEMBER

Both of the
Westinghouse Elec. & Mfg.
Co., East Pittsburgh, Pa.

IN THE PAST the effectiveness of transmission line insulation has been judged almost entirely by its 60-cycle flashover characteristics. On this basis the wide changes in spacing and diameter of suspension insulator units have affected the over-all flashover values but little. Recently, however, it has been realized that the criterion for insulation should be based upon impulse flashover characteristics rather than upon the 60-cycle behavior. Limited laboratory tests using impulse voltages showed that the impulse flashover voltage of insulator strings is changed appreciably by varying the diameter and spacing of the individual units. Economic studies show that, in general, low cost is associated with large diameter units spaced close together.

In a paper presented by Messrs. Fortescue and Conwell, and a discussion of that paper ("Lightning Discharges and Line Protective Measures," by C. L. Fortescue and R. N. Conwell, A.I.E.E. TRANS., v. 50, 1931, p. 1090–1100; discussion p. 1147) it was shown that on a transmission line equipped with ground wires, the reflections from tower footings altered the wave form so that the resultant voltage across the insulators had the approximate shape of the wave shown in Fig. 23. If the insulators are to be subjected chiefly to this type of wave, it is essential to determine how the insulators will perform under such waves.

To be comprehensive, an investigation of the characteristics of insulators should be made on a volt-time basis; that is, waves of long duration should be applied to the insulators, and the voltage varied so that flashover will take place in time lags ranging from sixteen or more microseconds down to one or two. The performance of the insulation then should be judged according to its application: If it is to be used on lines equipped with ground wires, the performance of the insulation should be judged by the flashover voltage at short periods of time; if it is to be used on lines not equipped with ground wires, its performance should be judged by long time lags as well as short. However, the majority of the transmission lines now being planned and constructed are to be equipped with ground wires. Therefore, the emphasis of this analysis will be placed on short time flashovers.

## TESTS ESTABLISHING A COMPARISON BASIS

Laboratory tests were made on suspension insulator assemblies and on bushings with the voltage wave shown by the oscillogram of Fig. 24. This voltage wave closely resembles the calculated curve shown in Fig. 23. The principal object of these tests was to determine the relation between flashovers with this type of wave and those given by standard volt-time curves.

The following crest voltages are the minimum values causing flashover of insulator assemblies made up of 10-in. units spaced $5^3/_4$ in. apart, when subjected to this type voltage wave:

| No. Units | Crest Voltage (kv.) |
|---|---|
| 8 | 1,050 |
| 10 | 1,240 |
| 12 | 1,550 |
| 14 | 1,800 |

From the volt-time curves shown in Fig. 25 it can be seen that these voltages correspond to flashovers at some time lag between 1 and 2 microsec. on $1^1/_2$–40 positive-wave volt-time curves. (A $1^1/_2$–40 wave is one in which the time from zero to crest is $1^1/_2$ microsec. and the time from to crest to half voltage on the tail of the wave is 40 microsec.) The minimum flashover voltage decreases and corresponds to longer time lags when longer-duration test waves are used. It has been shown previously that longer waves than that shown in Fig. 23 may be expected on lines having high tower footing resistances, and that effective ground wire protection can be had only with tower footing resistances less than 10 ohms. With higher tower footing resistances voltages appearing across the insulators become so high that it is uneconomical to insulate against strokes of even moderate intensity. For these reasons, the comparison of insulators for use on lines properly equipped with ground wires should be made at 2 microsec. as taken from volt-time curves.

Special field conditions may require a different wave upon which to base analyses; consequently, provisions were made for varying the magnitude of the $1^1/_2$–40 microsec. positive wave used in these tests, so as to give time lags of flashover ranging from 1 to 20 microsec. The results then were plotted in the form of volt-time curves from which insulator performance can be ascertained for any predetermined wave shape. In the event that some peculiar local condition necessitates the choice of an irregular wave as a basis of test, it is necessary to test only one combination of insulators with this wave. The flashover voltage values then may be referred to the volt-time curve to ascertain the corresponding time lag. The comparison of various types of insulators can be made at the corresponding time lag from their respective volt-time curves.

If the high voltage transmission line is not protected by ground wires, or if the ground wire protection is inadequate, then the voltage wave form across the insulators is not accompanied by reflections from tower footings; therefore the wave shape approximates that of the lightning discharge. The

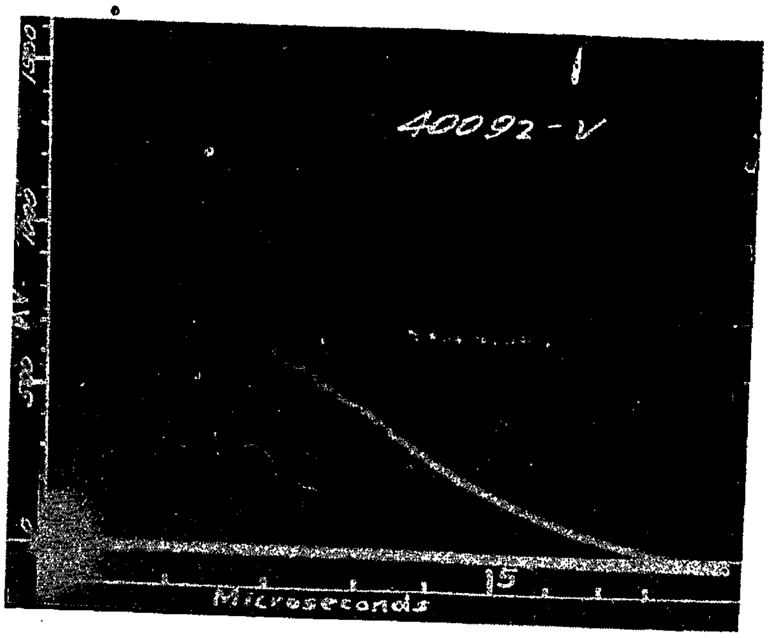

Fig. 24. Oscillogram of voltage impulse used for the tests described in this article

wave form in this case is of longer duration, ranging from 10 to 50 microsec.

## Diameter and Spacing Tests

To determine the relation between insulator dimensions and flashover characteristics of suspension insulator assemblies, a series of tests was conducted for which insulators of the cemented cap and pin type were made in a variety of shell diameters and unit spacings. The porcelain shells were standard in head, petticoat, and shed droop design except for a special $10^1/_2$-in. diameter unit designed for coastal duty. This unit had 10 per cent greater shed droop than the standard design. Heads of all these units were the same size so that all hardware was identical; this head size was the same as that of a standard-strength unit now most commonly employed upon high voltage lines.

Shell diameters of the insulators tested were, respectively, 7, $8^1/_2$, 10, $10^1/_2$, 12, and 14 in. Unit spacings ranged from a minimum possible value to a maximum value considerably greater than any spacing that has been employed for line insulation. The specific spacings used in the tests were, respectively, $4^3/_4$, $5^3/_4$, $6^1/_2$, $7^1/_2$, and 10 in. These variations in spacing were obtained by pins of various lengths being screwed into a threaded socket provided on the stud. This arrangement materially reduced the number of units required for the tests and afforded more comparable data because identical shells of each diameter were tested at all spacings.

Conventional 60-cycle dry and wet flashover tests were performed on strings of 4, 8, 12, and 16 units of each dimension combination; that is, the units in each string assembly were all of the same diameter and spacing. No non-uniform string assemblies were tested because these conglomerations have been found to be impractical line assemblies. The tests were made in accordance with A.I.E.E. Standard No. 41 pertaining to the conduct of normal frequency flashover tests.

Impulse flashover tests were made on the same string assemblies with a $1^1/_2$–40 microsec. wave of positive polarity. A cathode ray oscillogram was made of each impulse flashover, over 700 such records being obtained. These data were corrected for variations in atmospheric temperature and density, but no correction was made for the recorded relative humidity which ranged between 10 and 15 per cent. Correction factors for humidity have not been established, but at present are under consideration by the A.I.E.E. lightning and insulator subcommittee. It is the authors' opinion that the variation in impulse flashover voltage caused by changes in humidity during these tests is negligible. This opinion is based upon wet and dry impulse flashover tests.

Some of the data obtained from the impulse tests on various insulators are given in the replotted curves shown in Fig. 25. These curves were obtained from time lag curves, each of which was plotted from an average of 13 points. Some combinations of unit dimensions were not tested under the impulse wave as the test would become too long. The omitted combinations were so selected that they could be readily interpolated from the other tests.

Units found to be most effective under impulse tests were subjected later to arc tests to check the behavior of these diameter shells under high current impulses and power follow arcs. An eight-unit string of 12-in. diameter shells was subjected to more than 100 severe impulse flashovers, in addition to the normal impulse flashover characteristic tests, at an approximate rate of voltage rise of 6,000 kv. per microsec., and a current of approximately 5,000 amperes. These same units then were subjected to 60-cycle arcs of approximately 3,000 amperes for a duration of 2 sec. Since the 10-in. unit is the most common in practical use, this was chosen as a reference for comparison with the 12-in. unit. In the impulse tests neither the 10-in. nor the 12-in. units failed either by puncture or breakage. In the 60-cycle arc tests the performance of the 12-in. unit was as good if not slightly better than the 10-in. unit. These results are substantiated by service data available. All tests reported in this paper were made without auxiliary electrodes, such as rings and horns. The effect of such devices already has been investigated ("Impulse Flashover of Insulators," by J. J. Torok and R. Ramberg, A.I.E.E. Trans., v. 48, 1929, p. 239–45).

## Cost Considerations

In the selection of high voltage transmission insulators, the designer is confronted by two major considerations: first, the permissible cost of line insulation; and second, the selection of the maximum insulation available for that cost. Once the permissible cost of insulation has been decided upon, the most economic suspension insulator unit can be selected from examination of insulation and cost characteristics similar to those shown in Figs. 26 and 27. In Fig. 26 is shown the impulse flashover characteristics with respect to string length, of various assemblies of 10-in. and 12-in. diameter shells. These flashover voltages were taken at a 2-microsec. time lag for reasons advanced previously. It may be noted that for a given unit spacing and flashover voltage strings comprised of 12-in. shells are appreciably shorter.

In both Figs. 26 and 27, string length was chosen as the basis of reference, as it is a controlling factor in supporting structure dimensions. For a given flashover voltage, the shorter string length is more desirable on a tower cost basis, as it may reduce the length of the arm and height of the tower; or, with a given string length and the utilization of a more effective insulator, the flashover voltage will be increased and the number of outages due to lightning will be decreased. For example, in Fig. 26, a 1,500-kv. flashover at a 2-microsec. time lag is provided by a string length approximately 65 in. when composed of 12-in. units spaced $4^3/_4$ in., and by a string length approximately 91 in. when composed of 10-in. units spaced $6^1/_2$ in. A difference of 26 in. exists between the lengths of these strings. A steel tower design for use with the longer string of course would be appreciably heavier and more expensive than a tower with the same clearances and line height designed for the shorter string. Using 12-in. units spaced $4^3/_4$ in., a string length of 91 in. would have a flashover of 2,050 kv. as against 1,500 kv. for a string of the same length using 10-in. units spaced $6^1/_2$ in. apart. This means that an increase in flashover potential of 550 kv. is obtained by using the more efficient combination of diameter and spacing. These factors should exert considerable influence upon the choice of properly dimensioned suspension units.

### ECONOMIC SELECTION

To provide economic comparison curves the 2 microsec. time lag flashover characteristics of Fig. 26 were incorporated with the cost of the units to give the curves shown in Fig. 27. Cost values employed were those for a purchaser with packing and shipping expenses allowed to a shipping point 500 miles from the factory, and are based upon the physical dimensions of the units. Up to approximately 70-in. string length, a 12-in. unit spaced $6^1/_2$ in. provides insulation at the least insulator cost. This point corresponds roughly to the insulation considered as economically balanced for 138-kv. transmission on steel towers adequately protected by ground wires.

Beyond a string length of 70 in., a 12-in. unit

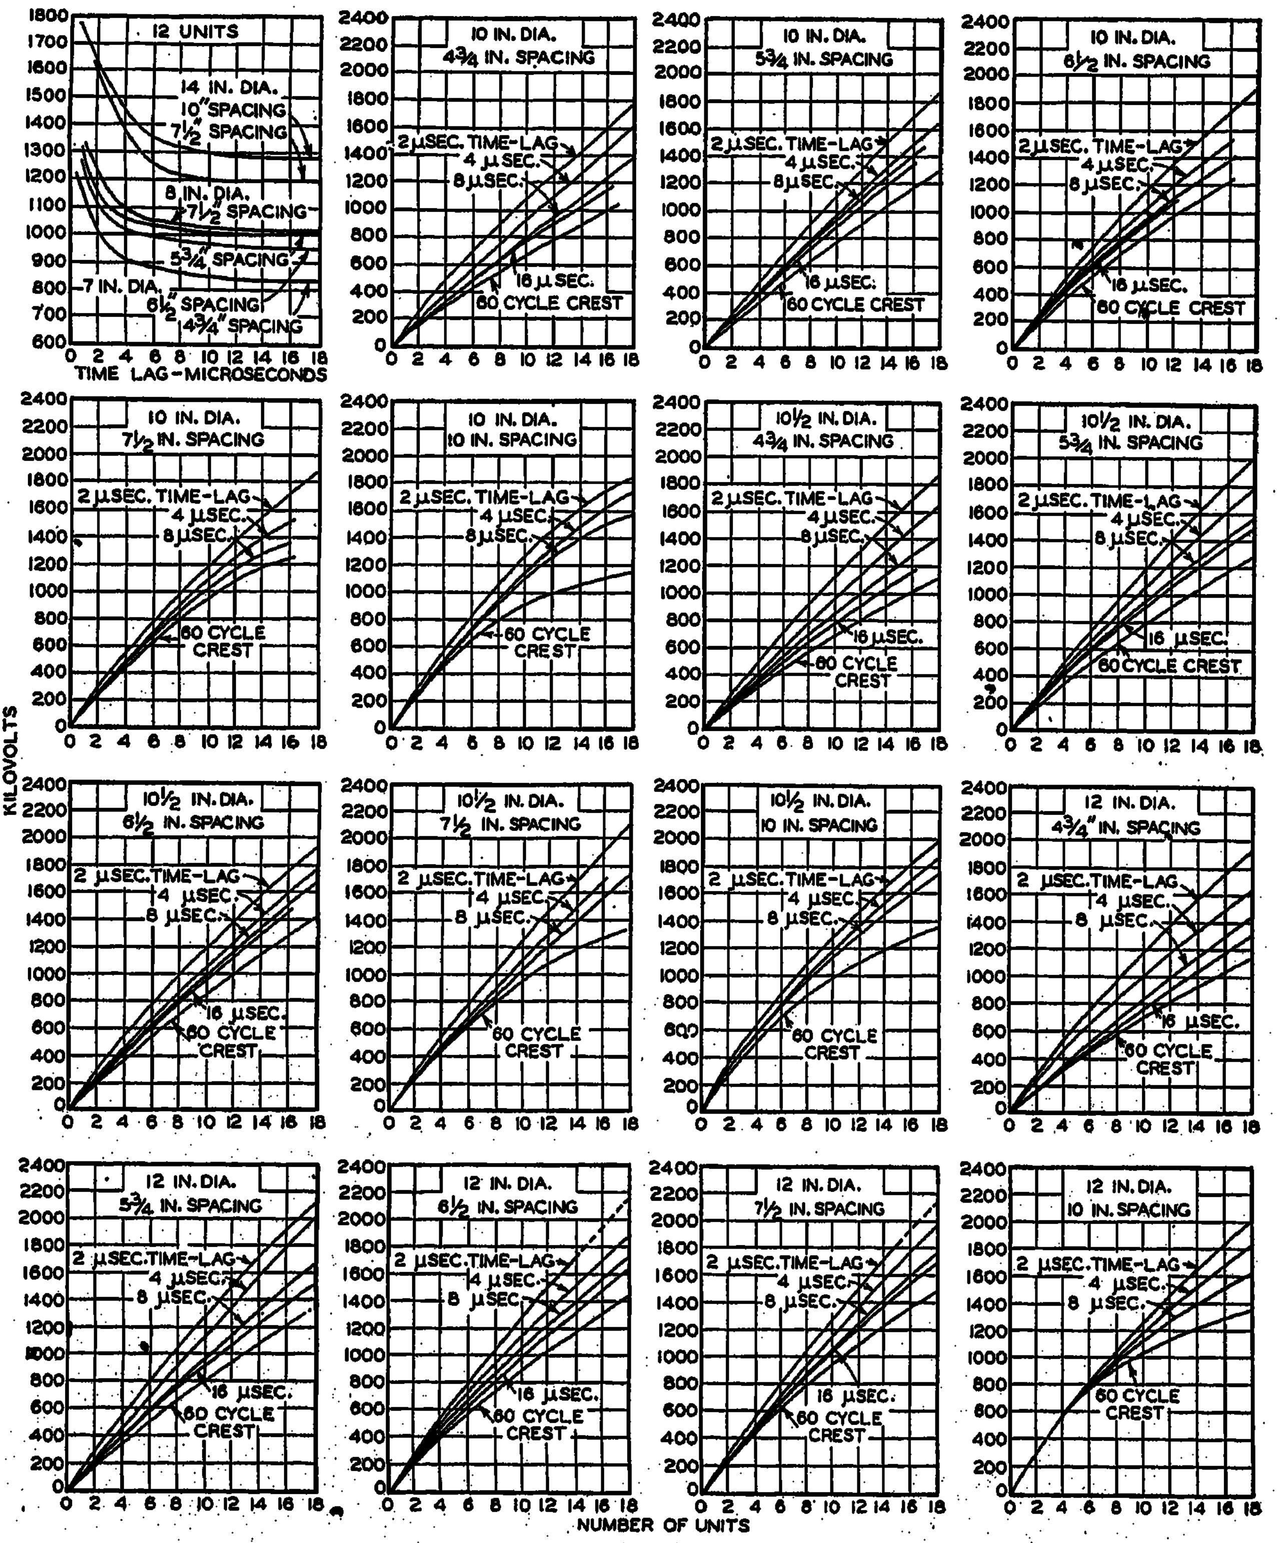

**Fig. 25. Flashover characteristics of suspension insulators**

All vertical scales show minimum flashover potential in kv.; horizontal scales (except upper left) show number of insulator units in the string spaced $5^{3}/_{4}$ in. shows the lowest insulation cost. Units 10 in. in diameter spaced $4^{3}/_{4}$ or $5^{3}/_{4}$ in. are the dimension combinations most commonly used at the present time for those string lengths. However, these units show much higher relative costs than 12-in. diameter units at the same spacing for string lengths of more than 30 in. Incidentally, a string length of 30 in. corresponds roughly to economically balanced insulation commonly employed for 69 kv.

Further examination of these flashover and cost curves clearly indicates a wide range of selection in the choice of the proper insulation. It should be noted, however, that to determine the maximum insulation for the least cost, Figs. 26 and 27 must be employed simultaneously. For example, at approximately 65-in. string length, 12-in. units spaced $5^{3}/_{4}$ in. provide a 1,500 kv. flashover rating at a relative cost of 1.76 or an arbitrary total cost of 2,640; whereas 10-in. units spaced $6^{1}/_{2}$ in. must have a string length of approximately 91 in. to provide the same flashover rating. This gives an arbitrary total cost of 1.93 times 1,500 which is 2,900 or approximately 10 per cent higher in cost with a 32 per cent increase in string length.

Low-cost units have been proposed for light duty, such as on wood construction and lower voltage transmission lines. Economic characteristics of such a unit are shown by the 9-in. diameter, 5-in. spacing curve of Fig. 27. Obviously, for light duty service requiring insulation corresponding to 60-in. string length (approximately 138 kv.) such units are desirable economically. For example, assume a 40-in. string of 9-in. units spaced 5 in. apart; from Fig. 26 this combination gives a flashover potential of 875 kv. at 2 microsec. time lag at the relative cost (Fig. 12) of 1.35 per kv. An equivalent string of 12-in. units, spaced $5^{3}/_{4}$ in. must have a length of approximately 40 in.; its relative cost is 1.7. Thus for the same electrical characteristics, the small unit shows a 20 per cent saving in cost. The economy of this smaller unit is the result of reduction in head size and consequently lower mechanical strength.

In wood pole construction, present practise is to use just sufficient porcelain to insulate the line for the normal operating voltage, and to depend upon the wood for impulse insulation. The insulator to be used for this type of service should have a low cost per kv. of 60-cycle flashover potential and mechanical strength slightly above that of the wood structure. Calculations of ultimate strengths of wooden structures now in use show that a unit having a mechanical strength of 7,000 lb. would be adequate.

## Conclusions

Principal findings of this study may be summarized as follows:

1. Two major factors in the design of steel tower transmission lines are (1) the shielding of the power conductors with properly located ground wires, and (2) maintaining the tower footing resistances as low as possible.

2. For towers of low footing resistance (on the order of 20 ohms) the wave is of short duration so that the minimum flashover voltage of the attached insulation corresponds to its breakdown voltage at 2 microsec. with a flat-topped wave.

3. In applying insulation to well protected high voltage lines, suspension insulators should be judged on the basis of their impulse flashover characteristics at 2 microsec.

4. Choice of insulation for lines either not protected or inadequately protected by ground wires is based upon impulse flashover values at long time lags, of the order of from 10 to 50 microsec.

5. Impulse flashover space effectiveness of suspension insulators improves with an increase in unit shell diameter at moderate spacings.

6. Impulse flashover space effectiveness for all unit diameters falls off with increase in unit spacing.

7. Flashover space effectiveness decreases with increase in string length.

8. Insulation cost for a given impulse flashover voltage generally is lower for larger diameter units and higher for larger unit spacings.

9. Available service data and laboratory tests show that a 12-in. unit is as serviceable as a 10-in. unit.

# Pacific Coast Convention Program Announced

TECHNICAL and entertainment programs have been arranged for the Institute's Pacific Coast convention to be held at Vancouver, B. C., August 30 to September 2, 1932 and promise 4 days which should be truly inspirational to members and guests. In addition to the formal program there are excellent facilities for all types of sports and entertainment for those intending to spend their vacation in Vancouver.

### TECHNICAL SESSIONS

Fourteen papers offer a variety of subject matter embracing both theory and recent practise in the electrical engineering field. These will be presented in 4 sessions, one each on the following: power generation; transportation, electrical machinery and metering; transmission and communication; and station apparatus. Those interested in power system developments and the segregation of hydroelectric power costs should find the first session of particular interest to them. The second and fourth sessions should appeal to those who are theoretically inclined, as they contain valuable papers in the measurements field, such as metering of symmetrical components and high accuracy bushing current transformers. Other subjects—circuit breakers, factory assemblies for substations, and the theory of the 3-wire d-c. generator with 2-wire static balancer—lend variety to these sessions. The third session should prove to be of general interest as it contains several papers in the power transmission field which are theoretical and several others describing large radio systems, a subject of broad appeal. In addition, at one of these sessions there will be presented 2 papers on railway electrification which are of popular interest.

### ENTERTAINMENT FEATURES

On the evening of the opening day, Tuesday, August 30, the president's reception will be held in the Hotel Vancouver. Following the reception, there will be a dance in the Oval Room, dress being optional.

The boat trip on the second day, August 31, will consist of a 4-hr. cruise on the S. S. "Princess Norah" around Vancouver harbor and the surrounding coast. The harbor is some 2 miles long and is set amid truly wonderful mountain scenery. Dinner will be provided on the boat, also an orchestra, and arrangements are being made for dancing on the deck.

A golf tournament will be held on September 1 at the Shaugnessy Heights Golf Club. That evening a banquet will be held in the Oval Room of the Hotel Vancouver, followed by the presentation of golf prizes and a good program of entertainment.

At the luncheon to be held under the auspices of the Electric Club on September 2, the speaker will be Capt. E. A. Wheatley, registrar of the Association of Professional Engineers in British Columbia, and his subject will be "Engineering Legislation." Captain Wheatley is a pioneer in the movement to raise the status of the professional engineer to that of the doctor or lawyer. He is intensely enthusiastic and is remarkably well informed. It is felt that his address will be of vital interest to all.

On the afternoon of September 2, inspection trips will be made by groups in private cars, including a visit to the University of British Columbia, as well as to a number of other points of interest. During the same afternoon, a bridge tea will be held for the benefit of the women. For those attending the student conference, a dinner will be held that evening at Union College, University of British Columbia. This will be followed by a student conference.

### REGISTRATION

A fee for "banquet and entertainment tickets" will be payable at the time of registration. These tickets will cover the dance after the president's reception on August 30, the boat trip on August 31, and the dinner on the boat, the banquet on September 1, and in the case of the women, the bridge tea on September 2. The charges for these tickets will be as follows:

| | |
|---|---|
| Members and men guests | $7.50 per strip |
| Ladies | 6.00 per strip |
| Students | 2.50 per strip |

Tickets for individual functions will be sold only to students.

Rates which will prevail at the Hotel Vancouver, convention headquarters, are as follows:

| | |
|---|---|
| Double room, with bath | $6.00 |
| Single room, with bath | 4.00 |
| Double room, without bath | 5.00 |
| Single room, without bath | 3.00 |

The Terminal City Club, 837 West Hastings Street, Vancouver, will accommodate visiting students at $1 per day.

Regarding transportation, the annual summer excursion rates will be in force and therefore no steps have been taken to obtain special rates. Vancouver may be reached from practically any part of the Pacific states by road, rail, air, or water.

### Committees

General convention committees and officers serving in the various departmental divisions of convention activities are: *Chairman*, G. R. Wright (A'12) district manager, Canadian General Electric Company, Ltd., 1065 Pender Street, West, Vancouver, B. C.; *vice-chairman*, L. B. Chubbuck (M'26) switching equipment engineer, Canadian Westinghouse Company, Ltd., Hamilton, Ont., Canada; *secretary*, W. D. Robertson (A'27) central station engineer, Canadian General Electric Company, Ltd., Vancouver, B. C.; *treasurer*, C. Arnott (A'27) electrical draftsman, British Columbia Electric Railway Company, Ltd., 425 Carrall Street, Vancouver, B. C. Committee chairmen include: F. W. MacNeill (M'22) *entertainment;* J. R. Read ('04) *finance;* A. Vilstrup (M'27) *hotels and registration;* V. W. M. Fouracre (A'31) *publicity;* L. B. Stacey (M'29) *reception;* J. Teasdale (A'24) *technical program;* E. G. Cullwick (A'26) *student activities;* C. W. Colvin (M'21) *transportation;* D. de M. Mertens (M'25) *golf;* and Mrs. F. W. MacNeill, *ladies' entertainment*. These are assisted by P. S. Biegler (F'29), E. A. Crellin (F'28), M. T. Crawford (F'22), R. J. Davidson (A'21), J. H. Hamilton (A'28), Paul Ransom (M'31), L. E. Reukema (A'24), J. A. Thaler (F'13), H. Vickers (M'26), and H. L. Vincent (A'25), all members of the local committee.

## Program

All technical sessions and the opening of the convention will be held at the Hotel Vancouver. Abstracts of papers to be presented at the sessions are scheduled for publication in the August 1932 issue of Electrical Engineering.

### Tuesday, August 30

**9:30 a.m.—Registration**

**9:15 a.m.—Meeting of District Student Committees**

**10:00 a.m.—Opening of Convention by President H. P. Charlesworth**

**10:30 a.m.—Power Generation**

*The Power System of the British Columbia Power Corporation, Ltd., E. E. Carpenter, British Columbia Electric Railway Co.

*Rock Island Development of the Puget Sound Power & Light Co., A. P. Newberry, Puget Sound Power & Light Co.

*Segregation of Hydroelectric Power Costs, W. S. McCrea, Jr., Dept. of Public Works, State of Washington.

**12:00 m.—Luncheon, Students and Counselors**

**2:00 p.m.—Transportation, Electrical Machinery, and Metering**

Reading Company's Philadelphia Suburban Electrification, G. I. Wright, Reading Co.

*Electrical Operation on the Cascade Division of the Great Northern Railway, J. B. Cox, General Electric Co.

Theory of Three-Wire D-C. Generator With Two-Phase Static Balancer, E. G. Cullwick, University of British Columbia.

*Metering of Symmetrical Components, G. R. Shuck, University of Washington

**8:00 p.m.—President's Reception**

### Wednesday, August 31

**8:00 a.m.—First Student Session**

**12:00 m.—Luncheon, Institute District and Section Executives and Student Counselors**

**2:00 p.m.—Second Student Session**

**5:30 p.m.—Boat Trip**

### Thursday, September 1

**9:00 a.m.—Station Apparatus**

*Shaping of Magnetization Curves and Theory of the Zero Error Current Transformer, A. C. Schwager and V. A. Treat, Pacific Electric Mfg. Corp.

*Factory Assemblies for Substation Design, H. M. Hobbs, Westinghouse Elec. & Mfg. Co.

*Operating Experience With High Voltage Circuit Breakers, R. E. Rowley, Dept. of Water & Power, City of Los Angeles

**2:00 p.m.—Golf Tournament**

**7:30 p.m.—Banquet**

### Friday, September 2

**9:00 a.m.—Power Transmission and Communication**

*Corona Loss Measurements for the Design of Transmission Lines to Operate at Voltages Between 220 Kv. and 330 Kv., J. S. Carroll, Stanford University, and B. Cozzens, Dept. of Water & Power, City of Los Angeles

*The Triple Harmonic Circuit in Three-Phase Power Systems, T. H. Morgan, Worcester Polytechnic Institute, and C. A. Bairos and G. S. Kimball, Stanford University, Calif.

*The Radio Plant of the R. C. A. Communications, Inc., H. H. Beverage, C. W. Hansell, and H. O. Peterson, of R. C. A. Communications, Inc.

*Radio Links in the System of the British Columbia Telephone Co., C. H. McLean, British Columbia Telephone Co.

**12:15 p.m.—Electric Club Luncheon**

**2:00 p.m.—Inspection trips**

**2:00 p.m.—Ladies' Bridge Tea**

**6:45 p.m.—Dinner at Union College, University of B. C., for those attending the Student Conference**

**8:00 p.m.—Student Conference**

### Rules on Presenting and Discussing Papers

At the technical sessions papers will be presented in abstract, 10 minutes being allowed for each paper unless otherwise arranged, or the presiding officer meets with the authors preceding the session to arrange the order of presentation and allotment of time for papers and discussion.

Any member is free to discuss any paper when the meeting is thrown open for general discussion. Usually 5 minutes are allowed each discusser. When a member signifies a desire to discuss papers on other subjects or groups, he shall be permitted a 5-minute period for each subject or group.

It is preferable that a member who wishes to discuss a paper give his name beforehand to the presiding officer of the session at which the paper is to be presented. Copies of discussion prepared in advance should be left with the presiding officer. Each discusser is to step to the front of the room and announce, so that all may hear, his name and professional affiliations. Discussions at the technical sessions are not reported. To be considered for publication, discussions should be written and mailed to the A.I.E.E., Editorial Department, 33 West 39th Street, New York, N. Y., on or before Sept. 16, 1932.

---

* These papers are under consideration for presentation at the Pacific Coast convention, but up to date of going to press have not been officially placed upon the program.

## Franklin Institute Honors Doctor Swasey

At this year's medal meeting of the Franklin Institute, May 18, 1932, Dr. Ambrose Swasey (HM'28) was awarded the Franklin Medal and certificate of honorary membership in the Franklin Institute. These are the highest honors bestowed by this organization, founded in 1824, the presentation taking place in the old hall of the Franklin Institute.

Doctor Swasey, who was honored as the inventor of a range-finding device which proved of great service during the World War, delivered an address, "Astronomers and Their Telescopes," upon this occasion. A banquet followed in the evening at the Bellevue-Stratford Hotel, at which Doctor Swasey and the recipients of other medals were guests of the Franklin Institute.

# Cleveland Convention A Pronounced Success

FROM Mexico City to Saskatchewan, from British Columbia to Florida, and even from England came members and their guests to attend the 48th annual summer convention of the Institute held at Cleveland, Ohio, June 20–24, 1932. A fitting tribute to the Cleveland convention committee, and an inspiring exemplification of the sturdy qualities of the Institute and its loyal members was the record of attendance, which was 1,022. From Cleveland and vicinity the total registration was 544, and from points other than Cleveland 478. Reflecting the attractive characteristics of the convention program of technical, social, and entertainment features, the attendance this year represents some 111 per cent of the average attendance of the last 10 summer conventions and 63 per cent of the maximum ever recorded at a summer convention (Swampscott, Mass., 1,616 in 1923), figures which compare far more than favorably with those of other similar national conventions held this season. Summer convention attendance for the past 10 years has been:

| | | |
|---|---|---|
| 1932 | Cleveland, Ohio . . . . . . . . . | 1,022 |
| 1931 | Asheville, N. C. . . . . . . . . | 525 |
| 1930 | Toronto, Ont., Canada . . . . . | 1,110 |
| 1929 | Swampscott, Mass. . . . . . . . | 1,000 |
| 1928 | Denver, Colo. . . . . . . . . | 500 |
| 1927 | Detroit, Mich. . . . . . . . . | 1,200 |
| 1926 | White Sulphur Spgs., W. Va. . . . | 350 |
| 1925 | Saratoga Spgs., N. Y. . . . . . . | 900 |
| 1924 | Chicago, Ill. . . . . . . . . . | 750 |
| 1923 | Swampscott, Mass. . . . . . . . | 1,616 |
| 1922 | Niagara Falls, N. Y. . . . . . . | 950 |

Particular credit is due the personnel of the Cleveland committees for the unqualified success of the convention and for the improvements in program brought about, through the adoption of some new features and the abandonment of some traditional activities. The many "little things" so often overlooked in the bustle of a convention were cared for in thoughtful detail.

### Annual Meeting

As the opening session of the convention, the annual business meeting was held in the Ball Room of the Hotel Cleveland, Monday morning, June 20. The minutes are given in this issue, p. 522. Presided over by President Skinner, the session proved to be of considerable interest to those having at heart the affairs of the electrical engineering profession. Following introductory remarks by President Skinner, Dr. W. E. Wickenden, president of Case School of Applied Science, Cleveland, extended to the guests a most hearty welcome to the city. His manner, humorous yet sincere, was most appropriate to the occasion.

Following the presentation by H. H. Henline, acting national secretary, of an abstract of the annual report of the board of Directors, President Skinner announced the results of the recent election of officers. (See p. 517.) In his response, President-Elect H. P. Charlesworth paid tribute to the men preceding him in the highest office of the Institute, and modestly stated his desire to live up to his new obligations.

W. H. Harrison then read the report announcing the winners of Institute prizes for papers given during 1931, after which President Skinner presented the prizes. Among those receiving awards, W. H. Harrison and R. N. Conwell were the only ones present to receive their prizes at the opening session.

Unfortunately, illness prevented the attendance at the meeting of Giuseppe Faccioli, winner of the Institute's Lamme Medal for 1931; also C. C. Chesney, who was to have given the tribute to Mr. Faccioli, was not present. However, C. H. Kline (Pittsfield, Mass.) read the statements of both men, and a deep impression was created on those in attendance by the sincerity of feelings expressed in their simple remarks. In Mr. Faccioli's acknowledgment of the award he stated that, largely for the benefit of the younger engineers who might be present, he wished to emphasize the fact that "it was a pleasure—not work—for me to do the things which have won for me the Lamme Medal."

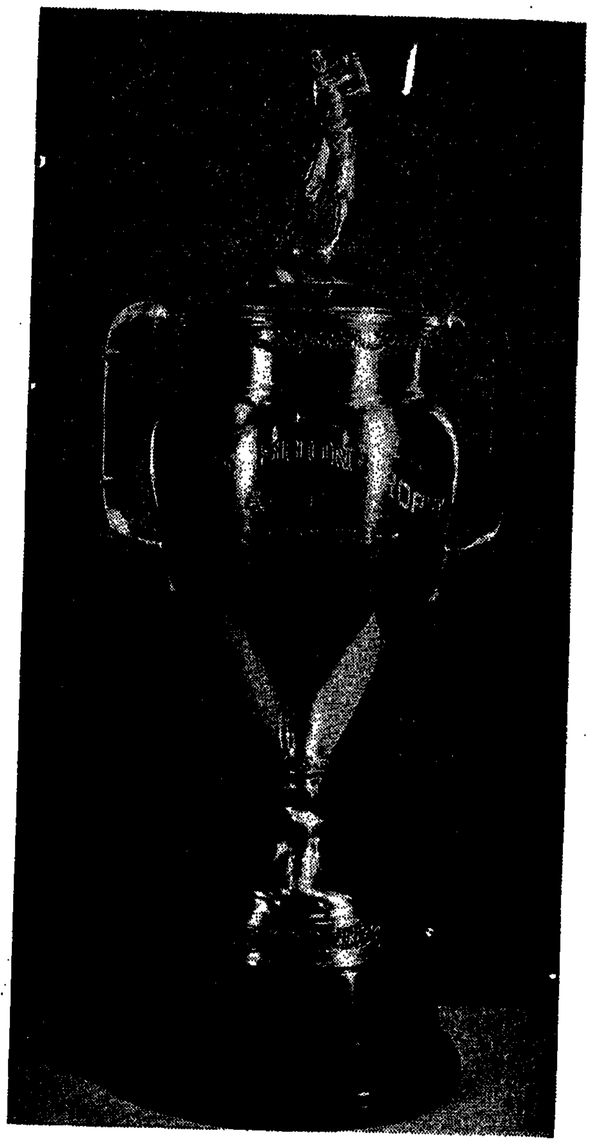
Doctor Skinner then delivered this year's presidential address, "The Institute and Its Members—Our Problems and Our Responsibilities." Printed in full in this issue of ELECTRICAL ENGINEERING, p. 472–6, its message is of direct concern to the membership of the Institute. Following the delivery of this address, the meeting was adjourned.

### Technical Sessions

Attendance at almost all of the technical sessions exceeded expectations, and in some cases exceeded arrangements which had been made for seating. The session on communication had an unusually general interest, and attracted many of the women guests. Other sessions, however, were more highly technical, and enabled the dissemination and discussion of much engineering information. At some of the meetings it was to be regretted that the lapel microphones used so successfully at previous Institute meetings were not employed. Abstracts of the summer convention papers were published in ELECTRICAL ENGINEERING for June 1932, p. 405–13, and will not be reviewed here. However, summaries of the discussions following presentation of some of these papers will be given in subsequent issues.

A special session for the entire membership was held on the morning of June 21, at which Dr. W. E. Wickenden delivered an address, "The Engineer in a Changing Society." This address, immediately recognized by those in attendance as being remarkable for its breadth of vision in analyzing the trends of society, especially as relating to the engineer, is published in this issue of ELECTRICAL ENGINEERING, p. 464–70. The increasing importance of the engineer in controlling the affairs of men was pointed out clearly, and encouragement given that greater social responsibility be accepted by the engineer.

Two afternoons were devoted to the conference of officers, delegates, and members usually held during the summer conventions under the auspices of the Sections committee and the committee on student Branches. A report of this conference is given in this issue, p. 522. A luncheon meeting of the board of directors of the Institute also was held, a résumé of this meeting being scheduled for a succeeding issue.



**The new Mershon silver golf trophy, for match play competition, stands 27 in. high above the base and is 12 in. in diameter**

### Trips and Entertainment

Cleveland's location made it particularly advantageous for the arranging of many attractive inspection trips, and all of these were very well attended. The outstanding trip, participated in by both members and guests, was the Akron-Barberton trip. This included a visit to the hangars of the Goodyear Zeppelin Corporation, and a tour of a rubber manufacturing plant attended by over 500, and dinner for 260 persons at the Mayflower Hotel, all in Akron, followed by a spectacular outdoor high voltage exhibition at the Barberton plant of the Ohio Brass Company. More than 800 witnessed this interesting demonstration. For the women, special trips and particularly appropriate entertainment features had been arranged for each day of the convention, and these proved to be very enjoyable. In the words of one woman guest, they were "priceless." The women's committee did a remarkably fine piece of work. At the Monday afternoon trip, 75 women were in attendance.

Evenings, too, were well utilized by both men and women. On Monday the president's reception and an informal dance were held; on Tuesday there was a boat trip on Lake Erie, in which 390 participated; on Wednesday the high voltage exhibition was staged at Barberton; and on Friday there were sight-seeing and other trips available.

The peak of the unusually attractive and popular social program was reached Thursday afternoon and evening when a variety of sports, a dinner, and an old-time party were arranged for every one at the beautiful grounds of Nela Park. These provided many hours of delightful relaxation for more than 500 participants. Ball games, golf, horseshoes, swimming, and tennis were among the sporting events during the afternoon, inspection trips being conducted simultaneously through the General Electric lighting institute. Following dinner and the presentation of awards to the winners of the various events scheduled during the week, including the golf and tennis trophies, a "regular old-time carnival" together with dancing in the outdoor pavilion were provided for the evening's entertainment. After extensive deliberation and no little worry, the Cleveland committee arranged this outdoor carnival program to take the place of the almost traditional banquet. If any doubts remained as to the success of such a departure from a formal program, they certainly were decisively obliterated by the results of the experiment.

### Golf

With two major trophies and many valuable prizes offered to winners of golf events, and with the long-standing Mershon tennis trophy supported by other attractive prizes for event winners, the noteworthy sports program provided for the summer convention by the Cleveland committee attracted wide attention, but merited more participants. Two prominent and highly exclusive Cleveland country clubs, Mayfield and Canterbury, graciously extended the courtesy of their facilities for the golf tournaments, while the annual tennis tournament was played on the University Club courts through the courtesy of that organization.

As announced in Electrical Engineering (Sept. 1931, p. 761) the original Mershon golf trophy, which had withstood competition since 1912, last year became the permanent property of L. F. Demming (A'11) of Philadelphia, Pa., as a result of his having twice won the right to have his name engraved on it, in 1916 and in 1931. This year, a new trophy was given by Past-President Ralph D. Mershon to be competed for by match play on a handicap basis, as heretofore, and subject to permanent possession by virtue of 2 winnings by an Institute member. The 16 men having the lowest net scores in a preliminary qualifying round were privileged to play through 4 successive elimination rounds to determine the ultimate winner.

A new trophy also was made available this year by Past-President William States Lee. This trophy will be awarded annually at the summer convention to the Institute member having the lowest net score for 36 holes, of which the first 18 may be the general qualifying round. Another innovation was the District Team event. Each District was privileged to enter a team of not more than 6 nor less than 4 players. The team having the lowest total gross score for 36 holes (4 men) was adjudged by the Cleveland sports committee as being the championship District team, and each of the 4 players on one team having the lowest total gross score for 36 holes was designated to receive a suitable individual trophy. Handicaps were based upon the 5 best 1931 scores made by the players on their regular courses, the 5 scores being averaged and the difference between that average and the par for the player's course noted. For medal play, $^4/_5$ of this difference was allowed as the A.I.E.E. tournament handicap; for match play, $^3/_4$ of the difference was allowed as the handicap.

Out of a field of 45 formal entrants, the 16 that qualified for the golf tournaments included: H. O. Anderson (A'27) New York, N. Y.; E. S. Atkinson (M'31) Battle Creek, Mich.; A. B. Cooper (M'16) and H. C. DonCarlos (F'18) Toronto, Ont., Canada; Cecil Gray (M'30) Richmond, Va.; R. A. Monroe (A'30) Pittsburgh, Pa.; G. V. Smith (M'28) Mansfield, Ohio; C. E. Stephens (M'22) New York, N. Y.; A. H. Sweetnam (M'18) Boston, Mass.; D. S. Young (A'28) Chicago, Ill.; L. M. Keating (A'22), L. R. Keiffer (A'22), G. A. Kositzky (F'29), Frank Quigley (A'32), S. B. Taylor (M'26), and C. H. Teskey (A'32) of Cleveland, Ohio. The second flight was narrowed to Anderson, Atkinson, Gray, Keiffer, Quigley, Stephens, Sweetnam, and Taylor, of whom the first four won their way into the third flight. The championship flight was fought between Atkinson and Keiffer with final honors and the Mershon Trophy going to Mr. Keiffer whose handicap was 19. The Lee Trophy was won by C. H. Teskey whose handicap of 7 gave him a net score of 143 for 36 holes against a par of 143.

Additional events provided for by the sports committee, and the winners of prizes therein, were:

1st low gross, C. H. Teskey, 79.
2nd low gross, G. A. Kositzky, 85.
1st low net, L. M. Keating, 72 (83 − 11).
2nd low net, A. H. Sweetnam, 73 (88 − 15).
1st blind bogey (72–88), G. V. Smith, 86.
2nd blind bogey (89–100), G. R. Canning, 96.
3rd blind bogey (101–130), G. V. Mueller, 102.

The foregoing special events were played in connection with the qualifying rounds at the Canterbury Club Monday, June 20. The following events were played in connection with Tuesday's match play at Mayfield Club:

Proximity of approach to No. 4 hole, G. R. Canning, 14 ft.
Proximity of approach to No. 17 hole, C. G. Ramsay, Manchester, England, 5 ft.
Low gross for 7 pre-selected holes, W. S. Lee, 31 (par 27).
Low net score, L. R. Keiffer, 68 (87 − 19, par 71).

Further events at Canterbury, in connection with the second flight:

Low net score, E. S. Atkinson, 70 (92 − 22, par 72).
Proximity of approach to No. 3 hole, C. G. Ramsay, 47 in.

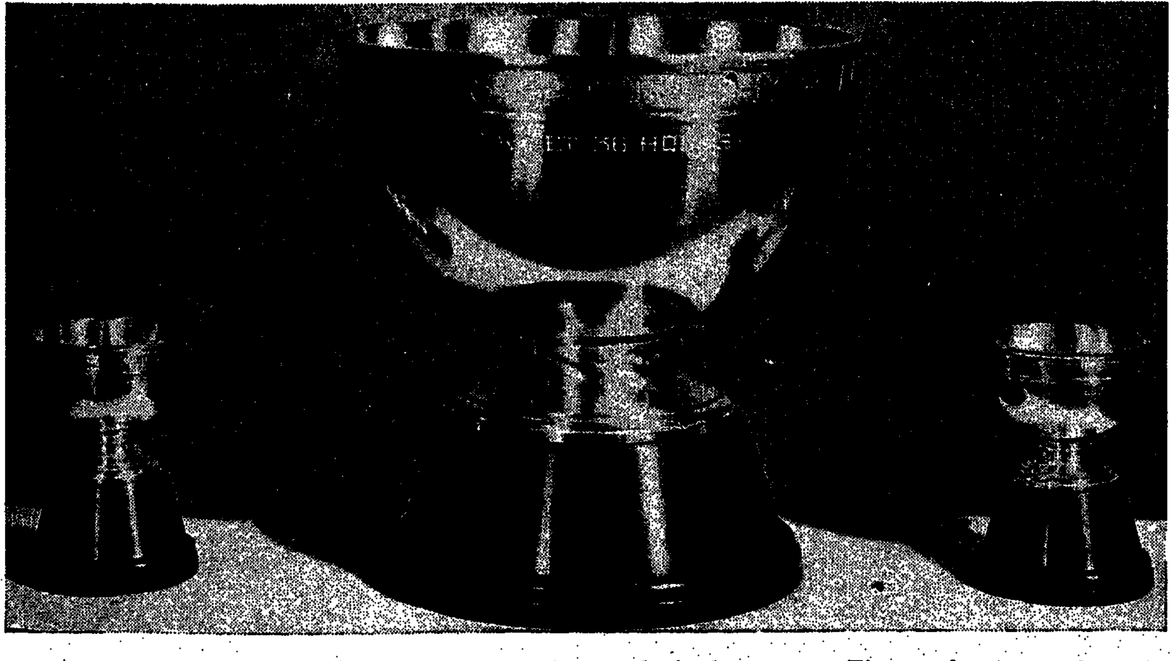
District No. 2 (Middle Eastern) took the team competition, L. M. Keating, G. A. Kositzky, G. V. Smith, and C. H. Teskey bringing in a total gross score of 691 for 36 holes (par 572).

### Tennis

With only 6 formally entered in the annual tennis tournament, the competition was not so widespread as in golf, but produced some lively sets and close scores. With the Mershon tennis trophy awaiting the winner of the men's singles the most active competition was in the singles events, although the Cleveland sports committee had prizes for the winners and the runners-up in each of the several events. With U.S. Lawn Tennis Association rules governing, all preliminary matches were decided by the best 2 out of 3 sets, the finals by the best 3 out of 5. The Mershon trophy is available to Institute members, the winner being recognized by having his name engraved on the cup and receiving a photograph of it, unless his be a second winning, in which event the cup passes permanently into his possession. With the addition of R. A. Monroe's name as the 1932 winner, the names engraved on the cup will be as follows:

1927—G. A. Sawin (M'13) East Pittsburgh, Pa.
1928—P. H. Hatch (M'29) Stamford, Conn.
1929—A. J. Gowan (A'23) St. Petersburg, Fla.
1930—E. F. Lopez (M'18) Mexico City, Mex.
1931—J. K. Peck (A'27) New York, N. Y.
1932—R. A. Monroe (A'30) Pittsburgh, Pa.

G. H. Gildersleeve (A'22) of Cleveland was runner-up; P. L. Alger (F'30) of Schenectady, N. Y., and E. F. Lopez (M'18) of Mexico City were eliminated in the semi-finals.



**The Lee golf trophy, 14 in. in diameter, for 36-hole low net. The replicas are 5 in. in diameter, one goes to each winner, whose name also is engraved on the big cup**

### Committees

The Cleveland general convention committee consisted of Robert Linsay, *honorary chairman;* G. A. Kositzky, *chairman;* A. M. MacCutcheon, *vice-chairman;* G. B. Schneeberger, *secretary-treasurer;* and F. E. Snell, *Cleveland Section secretary-treasurer.* To these leaders much credit must be given for the effective planning of affairs and for many of the novel and highly successful features included. The subcommittees and the affairs for which they were responsible are as follows:

**Banquet**—B. W. David, *chairman,* E. W. Henderson, L. E. Knapp, C. S. Ripley, D. Schregardus, and G. V. Smith.

**Entertainment**—C. N. Rakestraw, *chairman,* W. H. LaMond, T. D. Owens, C. S. Ripley, and L. A. S. Woods.

**Finance**—G. E. Miller, *chairman,* H. J. Dible, H. Dingle, A. D. Fishel, G. H. Gildersleeve, W. H. LaMond, H. L. Martien, R. L. Rathbone, W. M. Skiff, G. E. Snider, S. B. Taylor, E. F. Whitney, and E. A. Williford.

**Hotels**—I. H. Van Horn, *chairman,* J. Sayre Christie, L. R. Keiffer, and W. H. Stiner.

**Ladies Entertainment**—Miss Deany C. LaZan, *chairman,* Mrs. L. D. Bale, Mrs. F. W. Braund, Mrs. Henry B. Dates, Mrs. B. W. David, Mrs. Howard Dingle, Mrs. C. L. Dows, Mrs. E. J. Edwards, Mrs. E. W. Henderson, Mrs. G. A. Kositzky, Mrs. J. C. Lincoln, Mrs. A. M. Lloyd, Mrs. A. M. MacCutcheon, Mrs. E. H. Martindale, Mrs. C. N. Rakestraw, Mrs. G. B. Schneeberger, Mrs. J. M. Smith, Mrs. F. E. Snell, and Mrs. I. H. Van Horn.

**Meetings and Papers**—J. M. Smith, *local representative.*

**Publicity**—E. H. Martindale, *chairman,* C. H. Bunch, F. E. Harrell, Fennel Smith, and S. B. Taylor.

**Reception and Information**—H. B. Dates, *chairman,* C. J. Clements, H. J. Dible, R. C. Hardy, F. E. Harrell, J. C. Lincoln, P. D. Manbeck, R. S. McIntosh, R. C. Putnam, and R. L. Rathbone.

**Registration**—C. L. Dows, *chairman,* R. A. Carle, W. H. Fisher, F. A. Norris, F. Von Voightlander, and Thomas Wray.

**Sports**—A. M. Lloyd, *chairman,* Geo. Canning, W. G. Darley, J. L. Finnicum, W. E. McFarland, L. E. Miller, C. S. Ripley, and G. V. Smith.

**Technical Sessions**—H. L. Wallau, *chairman,* W. E. McFarland, J. J. Pokorny, and W. C. Saker.

**Transportation**—F. W. Braund, *chairman,* A. D. Fishel, G. H. Gildersleeve, H. T. Killingsworth, G. H. Mills, and C. E. Winegartner.

**Trips**—L. D. Bale, *chairman,* J. Callahan, Arthur Eastman, M. R. Gowing, C. A. Harrington, R. A. Hudson, A. H. Nicholson, and H. W. Pinkerton.

## Outline of Minutes of 1932 Annual Meeting

With President C. E. Skinner presiding, the annual meeting of the American Institute of Electrical Engineers was held at the Hotel Cleveland, Cleveland, Ohio, as the opening session of the annual summer convention, Monday morning, June 20, 1932.

The annual report of the board of directors was presented in abstract by H. H. Henline, acting national secretary. Printed copies were distributed to members in attendance and are available to any member upon application to Institute headquarters, New York, N. Y. The report, which constitutes a résumé of the activities of the Institute during the fiscal year ending April 30, 1932 shows a total membership on that date of 17,550. In addition to the 3 national conventions and 2 District meetings, 1,632 meetings were held during the year by the local organizations of the Institute in the principal cities and educational institutions in the United States, Canada, and Mexico. The report will appear in full in the quarterly TRANSACTIONS of the Institute.

The report of the committee of tellers on the election of officers of the Institute was presented, and in accordance therewith President Skinner declared the election of the following members taking office August 1, 1932:

*President:*

H. P. Charlesworth, vice-president, Bell Telephone Laboratories, Inc., New York, N. Y.

*Vice-Presidents:*

J. Allen Johnson, chief electrical engineer, Buffalo, Niagara & Eastern Power Corporation, Buffalo, N. Y.

E. B. Meyer, vice-president, United Engineers & Constructors, Inc., Newark, N. J.

K. A. Auty, sales engineer, Commonwealth Edison Company, Chicago, Ill.

G. A. Mills, chief engineer, Central & South West Utilities Company; vice-president, Pecos Valley Power & Light Company, Dallas, Tex.

C. R. Higson, superintendent of distribution, Utah Power & Light Company, Salt Lake City, Utah.

*Directors:*

G. A. Kositzky, chief engineer, The Ohio Bell Telephone Company, Cleveland, Ohio.

A. H. Lovell, assistant dean and professor of electrical engineering, University of Michigan, Ann Arbor, Mich.

A. C. Stevens, in charge, educational sales, General Electric Company, Schenectady, N. Y.

*National Treasurer:*

W. I. Slichter, professor of electrical engineering, Columbia University, New York, N. Y.

The board of directors for the next administrative year, beginning August 1, 1932, will consist of these officers, together with the following hold-over officers: C. E. Skinner (retiring president), East Pittsburgh, Pa.; W. S. Lee, Charlotte, N.C.; W. B. Kouwenhoven, Baltimore, Md.; W. E. Freeman, Lexington, Ky.; P. H. Patton, Omaha, Neb.; A. W. Copley, San Francisco, Calif.; L. B. Chubbuck, Hamilton, Ont.; J. E. Kearns, Chicago, Ill.; F. W. Peek, Jr., Pittsfield, Mass.; C. E. Stephens, New York, N. Y.; A. B. Cooper, Toronto, Ont.; A. E. Knowlton, New York, N. Y.; R. H. Tapscott, New York, N. Y.; L. W. Chubb, East Pittsburgh, Pa.; B. D. Hull, Dallas, Tex.; H. R. Woodrow, Brooklyn, N. Y.

President Skinner then congratulated President-Elect Charlesworth upon his election and presented him with the president's badge. Mr. Charlesworth responded with a brief address, which was enthusiastically received.

The report of the committee on award of Institute prizes, as published in the June 1932 issue of ELECTRICAL ENGINEERING, p. 418 was read by W. H. Harrison, chairman of the committee of award, after which the prizes were presented by President Skinner.

The Lamme Medal for 1931, which, as announced in the March 1932 issue of ELECTRICAL ENGINEERING, p. 209, had been awarded to Giuseppe Faccioli (A'04, F'12) of Pittsfield, Mass., was presented.

The annual presidential address then was delivered by President Skinner. (See p. 472–6.)

Adjourned.

(*Signed*) H. H. HENLINE
Acting National Secretary

## Officers, Delegates, and Members Hold Conferences in Cleveland

On Monday and Tuesday afternoons, June 20 and 21, 1932, the conference of officers, delegates, and members of the Institute was held at Cleveland, Ohio, as part of the recent summer convention. This conference was under the auspices of the Sections committee and the committee on student Branches. Present at this conference were delegates from 49 of the 60 Sections, 9 of the 10 District secretaries, and counselor delegates from 7 of the 9 Districts in which committees on student activities have been organized, as well as officers, officers-elect, and other members.

After a brief opening session on Monday afternoon, sessions A and B were held in parallel E. S. Lee, chairman of the Sections committee, presiding over session A devoted to Section activities, and Prof. W. H. Timbie, a chairman of the committee on student Branches, presiding over session B which dealt with problems concerning the Branches and Enrolled Students of the Institute. Tuesday afternoon was devoted to a joint meeting of the two groups to discuss subjects of common interest.

The topics in a conference program, which had been mailed to delegates and others in advance, are given in the following outline:

**Monday, June 20, 2:00 p.m.**

1. Opening of Conference:
Announcements by Everett S. Lee, Chairman of the Sections Committee
2. Remarks by President C. E. Skinner
3. Remarks by President-Elect H. P. Charlesworth
4. Remarks by Acting National Secretary H. H. Henline
5. Division into parallel sessions of Section and Student Branch delegates and members

**Session A—Section Meeting—Everett S. Lee Chairman**

6. Making the Institute of even greater value to the individual member
    a. The advantages of Institute membership—Everett S. Lee
    b. How the membership committee brings these advantages to the attention of prospective members—R. L. Kirk
    c. How the publications of the Institute maintain membership—E. B. Meyer
    d. How the committees of the Institute maintain membership—Prof. W. B. Kouwenhoven

e. How the Sections of the Institute maintain membership—J. J. Shoemaker
f. Problems of the finance committee—C. E. Stephens

**Intermission**

**Discussion**

**Session B—Student Branch and Enrolled Student Meeting—Prof. W. H. Timbie, Chairman**

7. Methods of teaching "Safety" to students
8. Organization of engineering clubs in local high schools—Prof. J. T. Walther and F. C. Young
9. Is it advisable to make student attendance at Branch meetings compulsory?
10. Suggestions for improving ELECTRICAL ENGINEERING
11. Suggestions for securing delegate representation for Branches located in Districts having fewer than 3 Branches
12. Student participation in District conventions—C. E. Baugh
13. Nature and content of program—Prof. M. S. Coover
14. Should some organization similar to Student Branches be set up in trade and industrial schools?—Prof. W. J. Seeley
15. Approved list of engineering colleges—G. L. Weller
16. Cannot the customary appropriations from headquarters to Student Branches be paid in advance as is done in the case of Sections?

### Tuesday, June 21, 2:00 p.m.

**Session C—General—Everett S. Lee, Chairman**

17. The professional status of the engineer—Prof. C. F. Scott
18. Legislation affecting the engineering profession—L. W. W. Morrow
19. Special committee on Institute policies—C. E. Stephens

**Discussion**

**Intermission**

20. Section and Branch cooperation
21. The coming year—H. P. Charlesworth

Copies of the annual report on Section and Branch activities for the fiscal year ending April 30, 1932 were distributed. These may be secured without charge to Institute members by applying to headquarters.

As indicated by the program, many subjects of great importance to the Institute were discussed. At the Section meeting, considerable attention was devoted to the matter of transfers, while at the student Branch and Enrolled Student meeting, much encouragement was given the formation of engineering clubs in high schools and the matter of providing talks before high school groups to be given by prominent and capable engineers.

RECOMMENDATIONS ADOPTED

The principal recommendations to the board of directors which were adopted are summarized briefly as follows:

1. Clarification of the relations between Associate and Member dues and the requirements for admission to the grade of Member.
2. Joint action by the Institute and other engineering societies to encourage the formation of engineering clubs in high schools.
3. The publication of one "feature article" in each issue of ELECTRICAL ENGINEERING.
4. The submission, by Institute headquarters to geographical District committees preparing for District meetings, of certain definite suggestions regarding the formation of a sub-committee to prepare for a student session and to make suitable arrangements for all phases of student participation in the meeting.

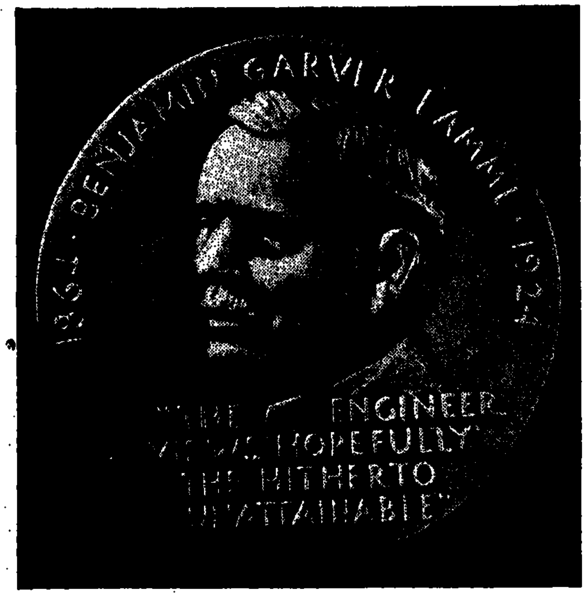
All of these recommendations were considered at the meeting of the board of directors held on June 22, and the following actions were taken (the numbered paragraphs refer to the corresponding recommendation):

1. Appointment of a special committee was authorized.
2. Referred to Institute representatives on the conference on certification into the engineering profession.
3. Referred to the publication committee.
4. Approved.

An abstract of the proceedings of the entire conference will be printed in pamphlet form and mailed to all delegates present; also to Institute, Section, and Branch officers. Any member of the Institute may secure a copy without charge by applying to headquarters.

## Lamme Gold Medal for 1931 Awarded

FORMAL presentation of the Lamme Gold Medal established by provision of the will of Benjamin Garver Lamme (deceased July 8, 1924) for the encouragement and recognition of "meritorious achievement in the development of electrical apparatus or machinery" took place June 20, 1932 at the annual business meeting of the A.I.E.E. during the summer convention at Cleveland, Ohio, with GIUSEPPE FACCIOLI (A'04, F'12) retired associate manager of the Pittsfield (Mass.) works of the General Electric Company, medalist for 1931. Mr. Faccioli (see p. 209, ELECTRICAL ENGINEERING, March 1932) was chosen to receive this award "for his contributions to the development and standardization of high-voltage oil-filled bushings, capacitors, lightning arresters, and numerous other features in high voltage transformers and power transmission." The first A.I.E.E. award of the Lamme Medal, made in 1928, was to A. B. FIELD (A'03, F'13) consulting engineer, Manchester, Eng., subsequent medals going to R. E. HELLMUND (A'05, F'13) chief electrical engineer, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., and W. J. FOSTER (A'07, F'16) consulting engineer, retired, General Electric Company, Schenectady, N. Y.



By Mr. Lamme's will, two other similar bequests were made, one to Ohio State University, the recipients of this medal to be a graduate or graduates of any of the university's engineering branches and the award to be "for meritorious achievement in engineering or the technical arts." The Lamme medals of Ohio State University will be presented this year to A. V. BLEININGER, chemist to the Homer Laughlin China Company, and to R. D. MERSHON (A'95, F'12 and past-president), consulting engineer and chemist, New York, N. Y.

## Junior Engineers Plan Industrial Projects

An interesting project program for junior members has been carried on successfully for some time by the Western Society of Engineers of Chicago, Ill., and more recently was taken up actively by the Cleveland (Ohio) Engineering Society. Junior members of these societies have organized themselves into fictitious holding, construction, and operating companies, and as such will undertake to solve the various problems that confront a typical industrial organization in undertaking new or enlarged operations including new manufacturing plant facilities.

The fundamental idea of the activity, as far as the societies are concerned, is to provide a continuity of interest in their junior member programs and to make these programs of definite interest and value to the junior members by giving the maximum number a definite responsibility in the various projects. The juniors consulted local firms having to do with the design, erection, and equipment of industrial buildings, and obtained from such firms the original specifications which had been given to the firm by the owners of a typical industrial project. With these plans in hand the junior members of the societies organized themselves into the necessary hypothetical finance, construction, and operating companies with related subsidiary units to study the various problems involved.

The junior members sent in formal "applications" for positions in the hypothetical companies outlining their qualifications, etc. The junior personnel of the various "companies" and "departments" will handle all of their own investigations, analyses, and design and operating problems, and will follow the work through to a complete "plant" design to meet economically the production and marketing requirements as determined by the various studies. After these plans have been completed they will be checked, through the courtesy of the local firms, against the actual solutions to the original problems, and against the actual plants themselves.

These activities seem to have aroused great interest among the junior members of both the Chicago and the Cleveland societies, and it seems probable that many of the Student Branches of the Institute might, to advantage, undertake similar projects with the helpful cooperation of related local sections.

# Summarized Review of Some Providence Meeting Discussions

PRINCIPAL discussions of Providence District meeting papers are summarized herewith. The papers to which these discussions refer were abstracted in ELECTRICAL ENGINEERING for April 1932, p. 263–7.

Only discussion submitted in writing in accordance with governing A.I.E.E. rules is summarized. Complete discussion, together with all approved papers, will be published in the TRANSACTIONS.

### PARALLEL-TYPE INVERTER

W. M. Goodhue (Cambridge, Mass.) described experiments which showed that static condensers may be omitted also when the a-c. line is replaced by a salient-pole damper winding synchronous motor. A 6-phase circuit with 6 thyratrons was used because it was preferable to operate the motor polyphase. The grids were excited by a polyphase induction phase-shifter consisting of a slip-ring induction motor with the rotor turned by a handwheel and worm drive, and insulating transformers for the rotor output. This phase-shifter was supplied directly from the terminals of the synchronous motor so that the inverter was permanently locked in step with the motor, and would automatically follow any speed changes. It was explained that the synchronous motor took load up to the maximum rating of the tubes, and showed no tendency to hunt or to fall out of step even when the shaft load was suddenly changed.

### ELECTRIC AND MAGNETIC UNITS

L. C. Eddy (Riverside, R. I.) believed that the general relations of units presented in the paper might prove to be of ultimate value for more thoroughly understanding universal relations of even certain forms of life. Both radio-activity and magnetism depend on certain relations or numbers of electrons or atoms much as animal life itself appears mainly where carbon is present in more or less definite relations with other elements.

### PERFORMANCE CALCULATIONS ON INDUCTION MOTORS

H. R. West (Pittsfield, Mass.) discussed this subject and advocated using a method of calculation which would give the desired accuracy with the least labor. He believed that the results of algebraic analyses, arranged in systematic form such as Mr. Veinott is using, could be used more profitably than they are at present.

R. E. Hellmund (East Pittsburgh, Pa.) discussed and explained why the discrepancy between the results obtained from load tests and those obtained by calculating methods from no-load values and other motor constants has been greater than it was 20 years ago. The up-to-date motors with smaller dimensions have higher flux densities and also more ampere conductors within a unit of space than was found in the earlier ones which most likely means in general more ampere conductors per slot than in the older designs. Then the zigzag and slot leakage fluxes would increase, tending toward greater saturation at load, especially in the tooth tips of partially closed slot machines. Since all theories deriving motor performance from the motor constants neglect the effect of saturation, he explained it was not surprising that in the modern designs there should be a greater discrepancy between such calculated results and tests made under actual load conditions.

P. C. Smith discussed several points in this paper and he believed the method permitted quick approximations or accurate calculations as desired. He questioned, however, the influence of friction and windage on the current through the shunt circuit and he did not believe that core loss always decreased with the load. In the determination of secondary loss in cases where the actual slip was available, he believed it might be advisable to substitute this for the secondary resistance.

Another discussion by P. H. Trickey (Springfield, Mass.) stated that he had used the author's method of calculation for over a year for both single-phase and polyphase motors rated between 2 hp. and 3 watts output and obtained very satisfactory results.

### STRAY-LOAD LOSS IN INDUCTION MOTORS

O. C. Rutledge (New Haven, Conn.) compared the results obtained in the paper by placing them on a percentage basis taking the input-output method as 100 per cent for each case. His analysis showed that method *A* gave low values while methods *B* and *C* gave permissible average values but there was a considerable spread from minimum to maximum. Mr Rutledge also presented curves obtained from tests on a 10-hp. wound rotor machine. Comparisons of both the input-output and direct methods were shown in curves plotted for loss against line current. These curves indicated that in the vicinity of full load the loss by direct measurement is of the same order of magnitude as that by input-output determination. However, the shape of the curve still left open the question as to whether or not the pulsation loss by the d-c. method is a correct representation of the true pulsation loss under load.

Messrs. O. C. Schoenfeld and S. F. Henderson (East Pittsburgh, Pa.) discussed the paper and they believed the method outlined had some merits although not theoretically correct nor could they check it experimentally. In their opinion proper consideration had not been given to the effect of saturation which could have considerable influence and as a result the d-c. short-circuit method gave values in excess of those obtained under normal load conditions. A tabulation of their tests showed full load efficiencies and stray load losses for 6 motors. The results indicated that the method proposed did not give sufficiently accurate results and the conventional efficiency in several cases gave results closer to the input-output value although the error was in the opposite direction. In general, the correction factors proposed by Linckh were correct but, as they were based on only a few tests, they should be further checked. In conclusion, the discussers did not believe that the method proposed simplified facilities or shortened time testing.

L. E. Hildebrand (Lynn, Mass.) also discussed this subject and cited the difficulties with present test methods. He believed that in all practical work a conventional efficiency test including a conventional load loss is certainly superior to ignoring load loss. Also this test with an average crew and equipment should be superior to the impractical input-output test providing a method is used for determining a conventional load loss which gives consistently repeatable results approximately equal to the true load loss. It was believed that such a method should be legalized and that the author's method *D*, with *C* as a permissible alternative for single-cage motors, seemed practical for a tentative permitted method.

Another discussion by H. L. Barnholdt (East Pittsburgh, Pa.) took exception to the proposed method *D* for squirrel-cage induction motors because only one test was indicated comparing this method with the input-output test. While this checked quite closely it was believed that, if a number of tests were made, they might show as wide discrepancies as methods *A*, *B*, and *C*. Further tests and greater consistency of test results were suggested as necessary before attempting standardization. The discusser also suggested an arbitrary allowance, say $^3/_4$ per cent, to cover stray-load losses on large induction motors. Input-output tests could be made when opportune so as to revise the allowance.

Still another discussion on this subject by C. G. Veinott (East Pittsburgh, Pa.) commended the author for his endeavor to measure the stray-load loss in polyphase induction motors. He thought the paper brought out reasons why the Institute should make a distinction between large and small motors and should, in his opinion, recommend the directly measured efficiency (input-output method) for the small motors. This opinion was based on the importance of stray-load losses in small motors and the ease, cheapness, and reliability of the input-output method. It was believed the dividing line between methods should be in sizes above 3 hp.

P. L. Alger (Schenectady, N. Y.), chairman of the committee on electrical machinery, discussed this subject as follows:

"The general opinion expressed was that, while it is very desirable to establish a standard method for determining induction motor load losses, and while Mr. Koch's proposals are fundamentally sound, much yet must be done in the way of study and tests before any method can be adopted as a standard.

"There was general agreement that measurement of the rotational losses by driving the motor at normal speed with direct current in the stator winding is an essential element in any direct measurement of stray-load loss. A difficulty arises, however, in the determination of the correct secondary $I^2R$ loss to be subtracted from the total rotational losses.

"If the rotor $I^2R$ loss is determined on the basis of the resistance corresponding to normal load slip, the value obtained is too small, since it does not include the full frequency rotor iron and copper losses.

These errors are very large on deep bar or double squirrel-cage motors, and for this reason methods *B* and *C* are regarded as undesirable for general use.

"While determination of the rotor losses by measurement of the standstill torque at full load current almost gives theoretically correct results, it is very difficult to carry out in practise on small motors, because of the irregularity of the torque position curve and the errors due to bearing friction.

"Determination of the rotor losses by measuring the impedance watts input and subtracting from it the primary $I^2R$ loss is convenient and approximately correct in the case of overhung slot motors, but it gives a value of rotor loss which is slightly too large, and, therefore, gives a value of stray-load loss somewhat too small. This error is somewhat offset by the existence of saturation in the flux leakage paths under normal load conditions. It seems practical, therefore, to get accurate results by this method, if a simple correction factor of perhaps 10 per cent is applied to the primary copper loss.

"In conclusion, method *A* should form the basis of standards for stray-load loss measurement in the case of overhung primary slot motors of one hp. and larger, with the addition of a multiplying factor of perhaps 1.1 for the primary copper loss on the standstill impedance test. Method *D* should form the basis of standards for stray-load loss measurement in the case of open primary slot motors (which are generally built in ratings of 20 hp. and larger). Direct input-output tests should remain standard for fractional hp. motors and should remain optional for larger motors.

"The induction motor subcommittee of the committee on electrical machinery is now reviewing this problem, and plans to submit some definite recommendations on the subject to the standards committee in the near future."

### SYNCHRONOUS MACHINE CHARACTERISTICS

J. W. Butler (Schenectady, N. Y.) discussed this subject and analyzed mathematically the calculation of damping torque for comparatively large sustained oscillations. He also emphasized the equivalent circuit shown in Fig. 9 of the paper which can be used to calculate any sort of a transient in a machine, including resistance, within the assumptions made. One particular use which was made of the circuit was in calculating decrement curves, for a fault on a generator feeding an impedance load, considering the effect of the load resistance in the time constants and magnitudes of the current.

In connection with this subject (S. H. Wright) cited certain prime advantages of low and high resistance dampers. Low-resistance dampers, he explained, tend to rapidly damp out swings which occur during symmetrical circuit conditions. For 2-machine stability problems, or multi-machine problems, where there are no serious compound oscillations, high resistance dampers give higher transient stability limits, especially for the longer clearing times, such as greater than 16 cycles where $f = 60$ cycles per sec. However, in the future, clearing time will probably be reduced to 8 cycles or less; interconnections and other factors will make compound system oscillations more important, so that greater damping ability, under symmetrical circuit conditions, of low-resistance dampers would become of paramount importance.

### CAPACITOR MOTOR DESIGN

L. A. Doggett (State College, Pa.) questioned the theory of the capacitor motor developed on the assumption of sine waves. An oscillogram of current waves taken when a capacitor motor running light was operating from practically a sinusoidal source showed values 4.4, 6.1, and 2.4, respectively, for line current, capacitor-phase current, and main-phase current. The wide departure of these currents from sinusoidal shape throughout the whole range of operation was brought out by an $I^2R$, $I^2X$ analysis of the load run test data. The wide discrepancies in tabulated $I^2X$ values was believed to indicate the presence of large harmonics.

P. L. Alger (Schenectady, N. Y.) commented on several points of L. A. Doggett's discussion. In his opinion the discussion was incomplete, when it simply pointed out the presence of harmonics and questioned the validity of the theory which neglects them, without some figures showing the actual magnitude of the errors they may introduce. If the ratio of the actual to the assumed sinusoidal copper losses were calculated from the test oscillograms, the results presented would be more interesting. In reference to the comparison of line $I^2X$ with those of the 2 branches the discusser pointed out that 3 out of the 9 cases checked closely and he believed that discrepancies in the other cases could be due to the inaccuracies inherent in the calculation from observed values of voltage, current, and watts.

Another discussion by C. G. Veinott (Springfield, Mass.) brought out that this paper showed the conditions which must be met in order to obtain operation equivalent to that of a 2-phase motor and incidentally brings to light important conclusions. For example, Fig. 1 in the paper showed that the ratio of capacitor phase turns to main-phase turns was of the order of the tangent of the power-factor angle of the motor when considered as a 2-phase motor with both phases like the main winding. It is, therefore, necessary to have control of the winding ratio as well as the external microfarads in order to obtain balanced operation. Consequently any polyphase motor cannot necessarily be operated as a polyphase motor from a single-phase source merely by the addition of a capacitor of suitable value in one phase.

### MULTIPLE CONDUCTORS

In connection with this subject Dr. Hillel Poritsky (Schenectady, N. Y.) described the method in which he obtained the exact solution for the maximum potential gradient of 2 cylinders having charges equal in magnitude and of the same sign. This required doubly periodic or elliptic functions for its treatment and the formula obtained is applicable to determine the critical disruptive voltage of a double conductor transmission circuit.

S. B. Crary (Schenectady, N. Y. ) discussed the comparison of maximum potential gradient obtained by approximate and correct formulas for the case of multiple conductors with charges of equal magnitude and the same sign. He explained that for practical cases eq. 5(*c*) in Miss Clarke's paper was developed. This formula corrects for the field distortion due to the conductors of the same phase by making 2 assumptions. First, the field distortion due to the conductors of the other phases and the ground plane is negligible. Second, the field produced by the other conductors of the same phase may be considered uniform in the region of the conductor under consideration. The accuracy obtained by using this approximate eq. 5(*c*) was shown graphically compared with the results obtained by using Dr. Poritsky's formula. It was essentially correct for a ratio of spacing to conductor diameter as low as 5 to 1. Another curve showed that if field distortion were neglected for this ratio it would have resulted in an error of 15 per cent.

Another discussion by W. W. Lewis (Schenectady, N. Y.) considered the economical aspects of the problem. He pointed out that the large weight of conductors required heavy towers and short spans. Also to obtain continuously decreased reactance, increased capacitance, and increased corona starting voltage, it was desirable to maintain as closely as possible the spacing between conductors in the same phase and in the different phases. This would require special insulating arrangements and supporting and separating yokes which would increase the expense. The discusser gave cost data compiled as a result of a comparative study of split conductor 345 kv. and 230 kv. lines as compared with conventional lines of the same voltage. From these data it appeared that at 345 kv. the 2 conventional lines had about the same cost per kv. and same yearly charge as one split conductor line. However, 2 conventional circuits have a greater total capacity and have the obvious advantage that the total flow of power is not dependent upon one tower line. At 230 kv. the comparative costs and yearly charges were about the same; however, the conventional lines had a considerable margin of greater capacity.

W. S. Moody (Pittsfield, Mass.) also discussed this subject in relation to the suggested methods of obtaining the reactive voltage by the use of transformers having very high magnetizing current resulting from the use of air gaps in their magnetic circuit or separate reactances distributed along the line. He explained that even the slight air gaps commonly used in European transformer practise have proved a very troublesome feature and they are gradually being dropped for our interleaved core construction. The 4 very long gaps required would drive a very heavy flux into the winding space of the transformer. This would necessitate very small conductors to avoid excessive eddy losses in them and would thus greatly weaken the windings mechanically. The varying density of the flux along the wire space also would create great difficulty in a parallel connection of any portion of the windings. Therefore, distributed loading coils would be preferable to obtain the necessary reactive voltage.

# Plans to Proceed for Colorado River Aqueduct

Information has been received from California to the effect that the Supreme Court of California rendered a decision on June 2, 1932, that the bonds for the construction of the Colorado River aqueduct are valid. These bonds total $220,000,000 and were authorized by the 13 cities composing the metropolitan water district of southern California on September 29, 1931. The purpose of the bonds is to finance an aqueduct to supply the Los Angeles metropolitan area with water from the Colorado River.

The main aqueduct will be 240 miles long. Storage facilities for regulating the flow will be provided, as well as distribution lines for delivering the water to the existing systems in the cities of the metropolitan water district. Power for pumping will be secured principally from the government plant at Hoover Dam, supplemented by smaller amounts at various parts of the system. The total static pumping lift will be 1,583 ft. It is contemplated that an average flow of 1,500 sec.-ft. will be diverted from the Colorado River and carried over the high lands to the Los Angeles basin.

At present it is planned to construct a diversion dam to raise the water surface 72 ft., creating a reservoir of 716,000 acre-ft. capacity. An opportunity also is afforded for the development of 80,000 kw. of electrical energy.

Although this great project will require the employment of a large force of men, a word of warning has been expressed to discourage large numbers of men coming to the district in the hope of securing work. It is stated that men are now available in southern California in excess of all requirements for every opening that the aqueduct work can possibly afford for months to come.

**Radio Study in Copper Country.**—Amateur short wave radio station W9YX and W9XAW at the Michigan College of Mining and Technology, Houghton, Michigan, was opened in January 1931. Since that time experiments in radio transmission have been conducted, consisting largely of attempts to determine what type of transmitters and aerials are best suited to the station's locality, the Michigan copper country. The most difficult problem is to overcome the great day-to-day variation in range of consistent communication. Receptivity has been found to vary, although it changes less than the transmission range. The staff at the Michigan college has tested Hartley and tuned-plate, tuned-grid transmitters and modifications which it has devised. Satisfactory communication was established March 1, 1932 with the present set consisting of a 100-watt tuned-plate, tuned-grid transmitter for continuous wave work, and a low power 7.5-watt phone set. The station operates on 40 and 80 meters. Aerials experimented with have variations or modifications of the Hertz antenna, vertical types of Zeppelin, horizontal Zeppelin, and single-wire-fed matched impedance. In February 1932 the staff returned to the voltage-fed Hertz type used earlier. The next experiments will consist of studying the efficiency of ultra short wave lengths of from 3 to 5 meters.

# A Tribute to Frank J. Sprague

A meeting of appreciation and tribute to Frank J. Sprague (A'87, F'12, HM'32 and past-president) is to be held Monday, July 25, 1932, at 8 p.m. in the Engineering Societies Auditorium, 33 West 39th Street, New York, N. Y. Doctor Sprague, engineer, scientist, and inventor, is to be honored on the seventy-fifth anniversary of his birth for his long service to industry.

F. J. SPRAGUE

(Electrical Engineering for February 1932, p. 139–40 outlined the achievements of Doctor Sprague, a pioneer in electrical applications, principally of electric motors, railways, and elevators.)

The meeting is being held under the auspices of the Frank J. Sprague anniversary committee, Gano Dunn, *chairman*, and C. T. Hutchinson, 52 William Street, New York, N. Y., *secretary*. Presidents and secretaries of the leading engineering and related societies, as well as a large group of other prominent individuals, are assisting the committee. The program for the meeting is as follows:

"An Engineer's Contribution to the World's Welfare," Dr. John H. Finley.

"An Engineer's Contribution to Transportation," Frank Hedley.

"Frank J. Sprague—A Tribute," Rear Admiral S. S. Robinson, U.S.N. (Ret.).

Response: Frank J. Sprague.

Members of the assisting societies and friends are invited.

**An all-welded condenser,** reputedly the largest of its kind ever built, is one of the principal features of interest in the newly enlarged Kearny, N. J., steam-electric generating station of the Public Service Electric and Gas Company. The condenser contains 11,900 24-ft. tubes, and, with an expected water rate of 105,000 gal. per min., it is expected to handle the 780,000 lb. of steam per hr., required by the newly installed 75,000-kw. turbine generator set, the recent completion of which is reported as increasing the capacity of the Kearny station from 214,500 to 289,500 kw.

# Elevators for Carlsbad Cavern

To eliminate a 750-ft. climb that formed an irritating but necessary part of a visit to the major features of the Carlsbad Cavern, N. M., the national park service has provided a passenger elevator by which tourists are taken to the main level of the cave. The development consists of providing a high-speed passenger elevator of modern design and safety equipment in a shaft drilled simultaneously from top and bottom through 754 ft. of rock to the main cavern level. The cavern in this national park contains the largest series of underground caverns ever explored, extending through 50 miles of known chambers and corridors.

The shaft size was 6 ft. 10 in. x 14 ft. 3 in. inside the concrete lining. The shaft was lined with gunite varying in thickness from $^1/_4$ in. to several inches. The elevator, house, shaft, and guide construction are entirely fireproof, with guide-rail supports of *I*-beam sections set into the rock walls.

The steel headframe is the center of a 3-story shaft house. The first floor is occupied by the elevator landing, the second floor is used as a generating room, and the third contains the machinery and controls. The roof will be used as an observation gallery. A novel feature of this building will be the provision for natural heating, cooling, and ventilation, using air from the cavern, which is always at a temperature of 56 deg.

The elevator is of modern electric type with self-leveling cage carrying 12 persons. It is planned to operate at a speed of 700 ft. per min. One elevator has been installed at the present time, and a second will be added later in the other compartment. With the exception of a few of the elevators in the Empire State Building, the present installation is the longest single-lift passenger elevator in the world. The equipment contains all automatic safety devices found in usual building installations.

—Excerpts from an article by F. A. Kittredge and W. G. Attwell, appearing in *Engineering News-Record*, June 9, 1932.

**Philadelphia Engineers Are Helping Each Other.**—An organization has been formed of unemployed engineers, who, true to their vocation, are doing their bit toward keeping up the morale of their fellow engineers, and serving industry by helping it in securing competent technical help. This organization is the technical service committee of the Engineers' Club of Philadelphia, Pa., located at 1317 Spruce St. The committee is an association of 12 national engineering societies, and its cooperation with the state employment commission makes it an organization of permanence. A very complete group of 850 highly technical men is ready to fill any gap that may exist in an organization. As stated by the committee, it is well worth noting that these technical men are plentiful now, but when the pendulum begins to swing upward again they will be scarce, and the employers who will take advantage of this opportunity now will have the most stable organization when business is back to normal.

# Letters to the Editor

## Eliminating Transients in D-C. Welding Generators

*To the Editor:*

In addition to the interesting papers by Messrs. S. R. Bergman ("Transforming Reactor Improves D-C. Arc Welding," Electrical Engineering, April 1931, p. 283–5) and by J. H. Blankenbuehler ("An Improved Welding Generator," Electrical Engineering, August 1931, p. 666–8) and the "Letter to the Editor" by C. J. Holslag ("Characteristics of Arc Welding Generators," Electrical Engineering, January 1932, p. 59) let me point out that I was probably the first to suggest the application of static transformers to d-c. generators supplied with multiple fields (separately excited and series fields for instance), in order to obviate the undesirable transients. In 1911, I took a French basic patent number 444,322, assigned to the "Société Alsacienne de Constructions Mécaniques," and some time later, the same idea was applied by R. Thury to high tension d-c. generators for constant current power transmission.

More recently, I patented the special application to arc welding generators, and in 1927 a full description of such improved generators was published in "Bulletin de la Société Alsacienne de Constructions Mécaniques" April 1927, p. 45; since 1928, they have been built by the French company "Als-Thom." Some years ago, complete information was given to American firms, but they were not interested in acquiring rights under my invention.

Very truly yours,
J. Bethenod (A'18)
(Consulting Engineer, 48 Quai d'Auteuil, Paris, France)

## Propagation Constant of a Transmission Line

*To the Editor:*

In the February 1932 issue of Electrical Engineering, p. 128–9, appeared an article by W. J. Creamer, Jr., "Propagation Constant of a Transmission Line" in which the author summarizes his problem and results thus: "The propagation constant of a transmission line usually is developed by means of differential equations...... A derivation of this constant which depends only on the application of Kirchhoff's laws and simple hyperbolic trigonometry is given below." I have the following comments to make:

1. There is nothing new in the method used by the author. Steady-state transmission theory in general may be and has been derived by the method used in the paper.

2. In deriving the result the author introduces an approximation which is unnecessary and is usually not made in deriving the propagation constant by this method.

In support of these comments, reference can be made to "High Frequency Alternating Currents" by Knox McIlwain and J. G. Brainerd, in which eq. 190 is the same as eq. 3 of the paper except that voltages rather than currents have been used; eq. 191 is the same as eq. 4 of the paper, and the derivation of the propagation constant of a line, as given on page 318, of the above-mentioned text-book, is more exact than that given in the paper. Incidentally it should be noted that the authors of the text-book cited clearly state that the material is not original, and indeed the method used in the paper is a relatively old one, known to antedate the text by some years.

Very truly yours,
H. C. Hart
(Moore School of Electrical Engineering, University of Pennsylvania, Philadelphia, Pa.)

## Savings and Investment

*To the Editor:*

According to the Progress Report of the American Engineering Council ("The Relation of Consumption, Production, Distribution," Electrical Engineering, June 1932, p. 373–9), the principal cause of a business depression is that savings are made at a rate faster than investment. Such a statement needs a word of explanation. The true measure of savings is the amount of goods in existence. All that exists now has been saved from some past time, possibly saved for only a few minutes, or possibly for thousands of years, but it all has been saved. Investment consists of saving in some form that will yield a profit. When a man saves his old clothes to do dirty work in, that is saving but not investment. The excess of saving over investment literally refers principally to that type of saving. Yet it is perfectly evident that the committee had some entirely different idea in mind.

The report suggests that it is referring to money, that when the community as a whole takes in more money than it spends either for consumption of goods or it places in investment, then we have a depression. This appears to be the thought behind the report, but a little consideration is enough to show that the community cannot possibly do anything of the kind. Mr. Brown has a hat and Mr. Smith $3. Mr. Smith may keep the $3 and Mr. Brown keep the hat, or they can trade so that Mr. Brown will have the $3 and Mr. Smith the hat, but the money is saved just the same. It is still saved by some one, no matter how many times it is spent. All the money issued is saved, and no more can be saved, no matter what is done in business.

Possibly the hoarding of money is referred to. There are times when money is hoarded in unreasonable amounts, but there is no reason to think that money was so hoarded in 1929. That seems to have been a time of free spending rather than hoarding. Money hoarding has been blamed for many things, and it doubtless has caused some damage, but evidence that it is a major factor in the business cycle is entirely lacking.

It is hard to tell what the committee had in mind when it referred to the excess of savings over investment. We cannot take the words in their strict literal meaning. That would produce a result evidently absurd. We cannot take them to mean saving money, for the community as a whole cannot change the amount of money saved. I cannot think of any interpretation of the statement that will stand examination on sound principles of economics. But whether the committee is advocating a sound or unsound economic program, when they use a statement as the foundation on which their reform program is based, this statement should at least be expressed so that there would be no doubt as to its meaning.

Very truly yours,
A. W. Forbes (A'12)
(Forbes & Myers, Worcester, Mass.)

## Injuries From Electric Shock

*To the Editor:*

I have read with considerable interest over the period of the past few months, the comments in "Letters to the Editor" in connection with the published results of Doctor Kouwenhoven's researches on electric shock, particularly the protests of our anti-vivisectionist members.

There can be no question but that these protests are in good faith and registered in a sincere belief that the taking of life for any purpose is wrong; however, this is no place to argue the merits and demerits of surgical experiments upon living specimens. I would like to state myself definitely on the relation of electric shock to electrical engineering as a profession.

Cases of electrical shock are almost without exception the natural result of the increased use of electrical power, they usually have as a victim a person directly connected with the electrical industry, the discoverers of a victim of electric shock are in nearly all cases employees of the electrical industry and as such would administer efforts at resuscitation, and last but not least, the only individuals, with but few exceptions, who appear to have any interest in combating the results of electric shock are the insurance companies and the electrical industries.

The question of improved procedure and methods of relieving persons of the consequences of electric shock is of as much importance to the electrical industry, and the world, as is the problem of building surge-proof transformers, and the protection of transmission lines from flashovers, not only from a humanitarian point of view but also from the commercial standpoint. Improved safety devices and insulation standards have greatly lowered the hazards of the electrical worker, but there will always be found in experimental work and construction projects a comparatively high possibility of death from electrical injury. And the possibility of saving a few of these lives through knowledge gained through experiments with animals is worth all of the rats of Hamlin, and more.

Whether or not these results should be published in the issues of Electrical Engineering can have but one answer. We of the electrical industry have no one but ourselves to protect us against electric shock; everything possible is done in the way of safety standards, but carelessness and chance are ever ready to take their toll. It is, therefore, left to us to forward and encourage in every possible way responsible research on electric shock and the prevention of death thereby, and that means both financial support and the publication of results.

Very truly yours,
F. W. Godsey (A'30) (310 Alden Ave., New Haven, Conn.)

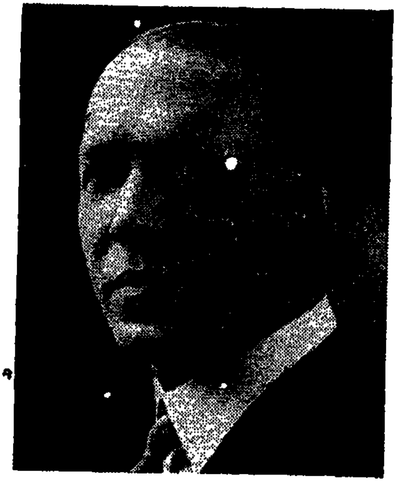
Kaiden-Keystone Studios
H. S. WARREN



R. N. CONWELL

Kaiden-Keystone Studios
A. E. SILVER

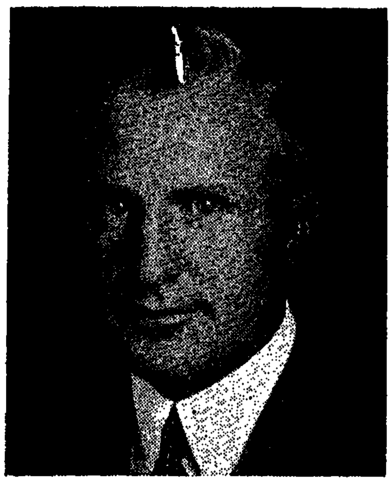
H. S. Warren (A'03, F'13) protection development engineer, the American Telephone and Telegraph Company, New York, N. Y., shares the 1931 A.I.E.E. national prize for best paper in engineering practise, which was awarded the symposium on coordination of power and telephone plant. Mr. Warren's contribution to this symposium was the paper "Status of Joint Development and Research on Low-Frequency Induction" in joint authorship with R. N. Conwell (A'15, F'31). A native of Oldtown, Maine, he went west in 1894 and entered upon an electrical engineering course at Leland Stanford, Jr. University, Calif. From this he was graduated in 1898 with his A.B. degree. His first practical electrical work was done while serving as electrician for the U. S. Fur Seal Commission. Immediately after graduation from the university he entered the employ of the Standard Electric Company of California, in San Francisco, and undertook the study of electrical constants and the transpositions for its projected 50,000-volt transmission line from Amador County to San Francisco. He next took a position with the California State Board of Harbor Commissioners and later in 1898 he engaged with the Nevada County Electric Power Company, Nevada City, Calif. But Mr. Warren's real life work has been in the field of communication. September 1899 he joined the American Bell Telephone Company, and since then he has devoted his entire effort to progress and improvement in this field. For many years he was in responsible charge of the design and development of some of the apparatus most vital to telephone systems. He designed and reduced to practical form, the loading coil which carried out the inventions of Doctor Pupin, designing cables and studying the loading of cables in connection with these inventions. He designed coil for, and reduced to practise also, the phantom circuit, an accomplishment not only highly interesting scientifically but one which made possible the operation of many thousands of miles of circuits. He is a member of Western Universities and the Engineers' Club, and past-president of the Telephone Society of New England.

R. N. Conwell (A'15, F'31) transmission and substation engineer for the Public Service Electric and Gas Company, Newark, N. J., shares with his coauthor H. S. Warren (A'03, F'13) in the 1931 A.I.E.E. national prize for best paper in engineering practise, which was awarded the symposium on coordination of power and telephone plant. The title of their paper was "Status of Joint Development and Research on Low-Frequency Induction." Mr. Conwell, a native of Anderson, Ind., is a graduate of Purdue University and of the George Washington University, Washington, D. C. As engineer in charge of acceptance tests of the sewage pumping station for the sewer department of the District of Columbia, his first professional work was done. In 1911 he was employed as cadet engineer by the Public Service Electric Company of Newark, N. J., later as laboratory assistant, and chief of the materials division of laboratory testing.

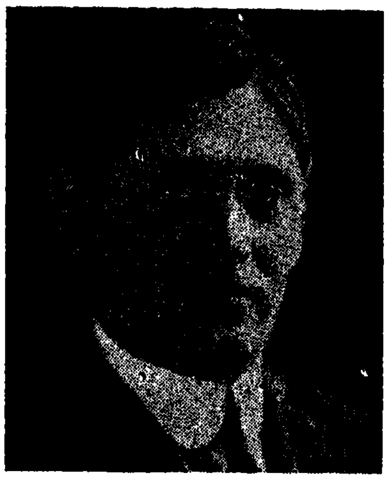
In transition to his present work he became assistant engineer of the engineering department in charge of station and substation design, system protection, and general engineering work. In 1922 he was made transmission engineer of the distribution department. As such he has organized and placed in operation a complete system of load forecasting and planning for budget purposes. To secure a more efficient distribution of power and a better continuity of service, Mr. Conwell completely redesigned and reconstructed the transmission system of his company. In 1925 he was appointed to his present position. His contributions to technical literature and discussion have been abundant and his committee activities with the A.I.E.E., National Electric Light Association, American Standards Association, American Committee on Inductive Coordination, National Fire Protection Association, and the Association of Edison Illuminating Companies, all too numerous to list. He also has to his credit over 2 dozen patents granted and pending. He is the inventor of the present type of inverse current relay for transmission and line work as made by the Westinghouse Electric and Manufacturing Company, and has done outstanding work in the inductive interference field.

C. A. CHURCH

A. E. Silver (A'07, F'26) consulting electrical engineer for the Electric Bond and Share Company, New York, N. Y., was among those to receive the 1931 A.I.E.E. national prize for best paper in engineering practise, awarded the symposium on coordination of power and telephone plant, the paper "Trends in Telephone and Power Practise as Affecting Coordination" prepared by him and W. H. Harrison (A'20, F'31) being an integral part of the prize symposium. Mr. Silver who is a native of Dexter, Maine, received his early education there. Entering upon an electrical engineering course at the University of Maine, he was graduated with the class of 1902, and then entered the test department of the General Electric Company at Schenectady, N. Y. In 1904 he accepted a position with the Raleigh Electric Company, Raleigh, N. C., remaining over a period of years in charge of its meter department, and also working on switchboard construction, generating stations, and overhead lines. With the coming of a new régime, in 1906, the departmental work was divided into steam and electric activities, Mr. Silver remaining in charge of the electrical work. Later in that same year he accepted the position of chief engineer and electrical superintendent of the Carolina Power and Light Company, Raleigh, N. C., this company representing the consolidation of several central stations and street railway properties of that section, as well as transmission and hydroelectric plants of the vicinity. In 1910 he became electrical engineer of the Electric Bond and Share Company and removed to New York City. The work with this company included responsible charge of design of generating stations, substations, transmission and distribution systems. Mr. Silver has served on both the power generation committee and the power transmission and distribution committee of the Institute, and since 1915 has been actively connected with committee work of the National Electric Light Association, now serving as counselor of the overhead systems committee, and of the foreign systems coordination committee; a member of the special engineering committee on lighting and marking airways and of the N.E.L.A.–Bell Telephone system joint development and research committee; and vice-chairman of the engineering national section. He has served also on committees of other well-known and national organizations including the Bureau of Standards. He is a Fellow of the American



W. H. HARRISON



J. C. MARTIN

G. L. LILLIE

C. E. HOUSTON

Association for the Advancement of Science, and a member of the Montclair Society of Engineers, of Montclair, N. J.

W. H. Harrison (A'20, F'31) who with A. E. Silver (A'07, F'26) his coauthor of the paper "Trends in Telephone and Power Practise as Affecting Coordination" shares in the 1931 A.I.E.E. national prize for best paper in engineering practise, awarded the symposium on coordination of power and telephone plant, is plant engineer of the American Telephone and Telegraph Company, New York, N. Y. Mr. Harrison who was born in Brooklyn, N. Y., was graduated from the electrical engineering course of Pratt Institute, Brooklyn, and in 1909 joined the New York Telephone Company in New York City, as repairman. His work until 1915 included apparatus inspection, assembling, and wiring; then he accepted a position on telephone circuit design work with the Western Electric Company in its engineering department. Three years later he joined the engineering Staff of the American Telephone and Telegraph Company for general plant maintenance engineering work; and in 1924 was made equipment and building engineer with general supervision of the engineering and design (including layout) of subscribers' station and the central office plant of the Bell system. He became plant engineer in 1929, this appointment giving him charge of the engineering, design, and layout of all parts of the Bell system plant including system relations with other wire-using utilities. Among other achievements, Mr. Harrison is said to have brought order out of chaos in connection with a large and important merger of several telephone systems in California, where he accomplished the standardizing and improvement of maintenance features of telephone equipment and contributed greatly to the application to and adoption of mechanical systems for telephone plants in the United States.

J. C. Martin (A'12) electrical engineer of Middle West Utilities Company, Chicago, Ill., who with H. L. Huber (M'23) prepared the paper "Status of Cooperative Work on Joint Use of Poles" which was a part of the symposium on coordination of power and telephone plant shares in the 1931 A.I.E.E. national prize for best paper in engineering practise awarded to this symposium. Mr. Martin was born at Solon, Iowa, and obtained his early technical education by home study with the International Correspondence School. In 1903 he engaged with the Cedar Rapids and Iowa City Railway and Light Company, doing office work for 2 years after which he was advanced to construction, line, and power plant work. In 1911 he joined the engineering department of the Pacific Power and Light Company, first as distribution engineer, later being made chief engineer in charge of all design and construction work. During this period he was located at Portland, Ore. In 1917 the Pennsylvania Power and Light Company of Allentown, Pa., chose him as its chief engineer. Here he remained until 1920, when he became western editor of *Electrical World*, located in Chciago. His history with the operating department of the Middle West Utilities Company started in 1923. By the Pacific Power and Light Company he was considered a specialist on electrical distributing systems.

C. E. Houston (A'32) assistant, department of physics, Texas Technological College, Lubbock, Texas, has received the South West District prize for Branch paper presented during the year 1931, in connection with the presentation of his paper "Accumulation of High-Potential Static Charges on Transmission Lines During Sand Storms." Mr. Houston was born at Salado, Texas, and earned his B.S in E.E. from Texas Technological College in 1931. From 1927 to 1928 he was chemistry assistant at the college, and from 1930 to 1931, physics assistant. In 1930 while an undergraduate student he undertook research work on static charges on transmission lines due to sand storms and it was during this interval that data contained in his prize winning paper were acquired. He has continued his research work and his thesis in connection with graduate work in physics also has this as a subject. Upon this he will receive his M.A. in August 1932.

G. L. Lillie (A'21) who has received both of the 1931 A.I.E.E. Canada District prizes for best paper and initial paper for his paper "Factors in Design of 115–230-Volt Distribution in a Modern Residential District," is assistant engineer of distribution for the Toronto Hydro-Electric System, Toronto, Canada. He was born at Colbourne, Ontario, Can., and for a while after his graduation from the University of Toronto in 1911, was employed by the Toronto Hydro-Electric System. In October of 1912 he left and for a few months was in the shops of the Westinghouse Company, at Hamilton, Can. He then returned to the University of Toronto for a postgraduate course, and in 1913 was graduated with his degree in electrical engineering. He at once returned to the employ of the Toronto Hydro-Electric System, but in September 1917 left to join the Canadian navy. He received his discharge in January 1919 and again returned to his company, where he has continued to serve to date.

C. A. Church (Enrolled Student) University of Colorado, Boulder, Colo., has been selected to receive jointly with N. R. Damon, coauthor, the 1931 A.I.E.E. North Central District prize for Branch paper. This choice was made based upon the paper entitled "New Ideas for High Voltage Circuit Breakers." Mr. Church was born at Goodell, Iowa. His high school education was obtained at Longmont, Colo., where he was graduated with honors in 1927. As a Fellow at the University of Colorado, he received his B.S. in E.E. there in 1931. At present he is engaged in graduate study and research in electrical engineering at the University of Colorado. This work is supplementary to that by which he earned his M.S. degree June 1932. His fraternal affiliations are Tau Beta Pi, Eta Kappa Nu, and Sigma Xi.

W. B. Kouwenhoven (A'06, M'22) vice-president of the Institute for the Middle Eastern District, and professor of electrical engineering and assistant dean of The Johns Hopkins University, Baltimore, Md., has been accorded special honors by those in charge of the International Electrical Congress being held in Paris this month (July 4–12, 1932). Doctor Kouwenhoven in collaboration with Dr. O. R. Langworthy prepared a paper "Injuries Produced by Contact With Electric Circuits" for presentation in Paris, embracing the findings of their original and extensive research work at The Johns Hopkins University. According to a report recently received, "Because of the interesting work of Messrs. Kouwenhoven and Langworthy [the committee] listed their contribution as a report and not as a paper." The significance of this recognition is that the paper will appear as an independent, individual contribution and not as a part of any general report; also the authors are exempt from the payment of membership fees, and in addition will be awarded the sum of 2,000 francs as part payment of expenses for attendance at the congress. (EDITOR'S NOTE: The important findings of Doctor Kouwenhoven's work have been covered from time to time in his contributions to the pages of ELECTRICAL ENGINEERING; others are scheduled for the future.)

L. A. MAGRAW (A'07, M'13) president and general manager of the South Carolina Power Company of Charleston, S. C., at a recent Southeastern Division conference of the National Electrical Light Association was chosen to serve as its president; and J. M. BARRY (A'11) vice-president in charge of operation for the Alabama Power Company, Birmingham, Ala., became the second vice-president of this same division of the N.E.L.A.

R. A. MILLIKAN (M'22) director of the Norman Bridge Laboratory and chairman of the executive council of the California Institute of Technology, Pasadena, Calif., recently was reelected president of the board of directors of the National Advisory Council on Radio in Education. M. I. PUPIN (A'90, F'15, HM'28 and past-president) also received reelection to the vice-presidency of the Council.

S. A. KNIGHT (A'31) who last year was assistant engineer for the Irak Petroleum Company, Ltd., of Manchester, England, with headquarters in Tuz Khurmatu, Province of Irak, recently returned to Great Britain to become assistant technical engineer for the Central England Board, in its North West area. The home office of the board is at Manchester, England.

J. E. E. ROYER (A'15) general manager of The Washington Water Power Company, Spokane, Wash., has been made vice-president as well. Mr. Royer who came to The Washington Water Power Company in 1907, became assistant superintendent of the light and power department in 1919, assistant general manager in 1924, and general manager 2 years ago.

S. P. GRACE (A'03, F'21) assistant vice-president of the Bell Telephone Laboratories, Inc., and well known for his popular lectures on various advances in the science of communication, recently received the degree of Doctor of Engineering from the University of Michigan, and the honorary degree of Doctor of Laws from Notre Dame University.

GEORGE FISKE (A'11) who has been serving the General Electric Company at Kansas City, Mo., as its assistant manager, now has been made manager of the company's office there, it was recently announced. Mr. Fiske joined the company in 1904 as a test man, and barring military service 1917–19, has been continuously with it to date.

G. W. ELMEN (M'21, F'27) telephone engineer for the Bell Telephone Laboratories, Inc., and inventor of the magnetic alloys, permalloy and perminvar, has received the honorary degree of Doctor of Engineering from the University of Nebraska, his alma mater. At the laboratories, Mr. Elmen is in charge of research in magnetic materials.

E. R. HEDRICK (M'25) professor of mathematics and chairman of the department of mathematics at the University of California, Los Angeles, has been awarded the title of "Officier d'Academie" by the French government, "for services rendered to the cause of culture and science."

F. L. KRADEL (A'27) who for some time was sales engineer for The Champion Switch Company of Kenova, W. Va., and subsequently removed to Millvale, Pa., recently became representative for the Royal Electric Manufacturing Company, Chicago, Ill., in its southern Pennsylvania and West Virginia territory.

J. W. MCCARTIN (A'20) previously of the engineering department of E. L. Phillips and Company, New York, N. Y., now is chief operator for the Nassau division of the Long Island Lighting Company, Glenwood Landing, N. Y. His office with the Phillips company was that of power plant and substation designer.

A. H. GFRORER (A'14) for the past 13 years chief engineer of the Automatic Transportation Company of Chicago, Ill., and in addition to these duties, for the past 3 years holding like office with the Barrett Cravens Company, Chicago, Ill., resigned from both of these organizations as of June 30, 1932.

K. W. JOHN (A'29) has resigned his position as chief electrician of the Graham Paige Motors Corporation, Detroit, Mich., and on June 1, 1932 became affiliated with the United States Rubber Company, Detroit, Mich., as technical engineer of its plant in that city.

N. MIRIDJANIAN (A'31) who for the past year or so has been associated with the Columbia Graphophone Company, Istanbul, Turkey, recently established the "Gans" Electroplating Works, which he announces is the first modern electroplating shop in Istanbul.

DICK PYPER (A'29) who in the past has been associated with the Southern California Edison Power House No. 3 at Big Creek, Calif., recently became hydroelectric power house operator of the Turlock Irrigation District, at Turlock, Calif.

W. R. THORSON (A'26) who previously was superintendent of electrical distribution for the Consumers Power Company at Hudson, Mich., recently was made superintendent of public works for the City of Waverly, Iowa.

P. W. BUCHHART (A'32) who in 1931 served the Pennsylvania Railroad Company, Philadelphia, Pa., as draftsman, is now engineer and director of the International Patent Commercialization Company, Inc., New York, N. Y.

W. T. POWELL (A'14) previously patent engineer for the Stromberg-Carlson Telephone Manufacturing Company, Rochester, N. Y., now is serving the General Railway Signal Company, that city, as its patent attorney.

H. K. V. TOMPKINS (M'31) who last year was associated with the Gulf Produce Company, Houston, Texas, now is assistant to the president of George F. Getty, Inc., and Pacific Western Oil Company, Los Angeles, Calif.

R. B. H. ROCKWELL (A'29) previously in the operating engineering department of the Georgia Power Company at Atlanta, Ga., now has been transferred to that company's office at Macon, Ga., as lighting engineer.

J. P. GRABLE (A'22) who heretofore has been identified with the General Cable Corporation, Fort Wayne, Ind., now is coil engineer of the American Enameled Magnet Wire Company at Port Huron, Mich.

ERNEST KAUER (A'25) who in the past has been president of the CeCo Manufacturing Company, Providence, R. I., recently changed to become president of the Molding Corporation of America, of that city.

W. S. LEE (A'04, F'13 and past-president) chief engineer of the Duke Power Company, Charlotte, N. C., recently received the degree of Doctor Laws from The Citadel Military College of South Carolina.

THOMAS PADEN (A'28) formerly superintendent of distribution of the Ohio Edison Company, Youngstown, Ohio, now is electric superintendent of the Pennsylvania Power Company, New Castle, Pa.

C. N. JOHNSON (A'17, M'26) engineering manager of the Westinghouse Electric and Manufacturing Company, Philadelphia, Pa., now has joined the company's forces at 150 Broadway, New York, N. Y.

W. C. SEALEY (A'25) who recently became identified with the Allis-Chalmers Manufacturing Company's office at Milwaukee, Wis., has been transferred to its works at Pittsburgh, Pa.

E. F. MEKELBURG (A'21, M'30) who has been serving Cutler-Hammer, Inc., Milwaukee, Wis., as supervisory engineer, now is identified with the Industrial Controller Company of Milwaukee.

F. W. Pembleton (A'20) formerly winding supervisor of the General Motors Radio Corporation, Dayton, Ohio, now is chief engineer of the Volume Control Service, Fort Wayne, Ind.

L. R. Milburn (A'20, M'31) who was assistant electrical engineer of the Great Lakes Steel Corporation, Detroit, Mich., now is electrical engineer for that same company at Ecorse, Mich.

R. R. Black (A'30) once the General Electric Company's electrical engineer at Fort Wayne, Ind., now is engineer of the Polymet Manufacturing Corporation, New York, N. Y.

C. D. Raymond (A'27) who has been an electrical engineer for the General Electric Company at Newark, N. J., recently joined the Ellenville Electric Company, at Ellenville, N. Y.

C. H. Roth (A'11) who has been president of Roth Brothers and Company, Chicago, Ill., now is president of the Light Sensitive Apparatus Corporation, at Niles Center, Ill.

Herbert Hoover (HM'29) President of the United States, recently received from Gettysburg College, Gettysburg, Pa., *in absentia* the degree of Doctor of Science.

André Mestraud (M'24) of Lanobre, Cantal, France, has recently been made directeur de l'Energie Electrique du Littoral Meditarraneen, at Marseille, France.

# Obituary

Walter Throop Kendall Brown (A'07, M'13) chief of the engineering staff of the Winchester Repeating Arms Company, New Haven, Conn., died at his home at Short Beach, Conn., June 12, 1932. He was born at Paterson, N. J., February 26, 1874, and after obtaining his elementary education in the New York State public schools, entered upon a scientific course at the Williston Seminary at East Hampton, Mass. Thereafter he attended the Cincinnati Art Academy for design and woodcarving; then, returning to the New England section, joined the night school of the Brooks Locomotive Works, well known in the nautical world. Pursuing this bent, he completed a course in ocean navigation with the International Correspondence School, also taking up the subjects of electric railways, lighting and interior wiring, electric transmission, and steam boilers. He then made an exhaustive 3-year study of the deviation of the compass on iron ships. Mr. Brown was at one time chief petty officer in the United States Navy, spending $1^{1}/_{2}$ years in the pay department and $2^{1}/_{2}$ years on construction repair equipment and electrical equipment. He has also served as quartermaster and officer of the U.S. and British Merchant Marine. From 1904 to 1912 he was with the Stanley Electric Manufacturing Company and the General Electric Company's Pittsfield Works, as erecting engineer for central stations, assistant works manager for fire protection, and electric superintendent of maintenance and equipment. In 1912 he became assistant general manager and supervising engineer of the Star Electric Company, subsidiary of the General Electric Company, and as such had charge of checking fire alarms and police telephones; organized and put in a complete manufacturing system, and supervised engineering manufacture and construction. In 1915 he joined his last company, the Winchester Repeating Arms Company of New Haven, as equipment engineer and manufacturing engineer. He was particularly successful in organization work and the training of young engineers.

Besides his Institute connection, Mr. Brown held membership in the Society of Military Engineers, the Spanish War Veterans, the Massachusetts Society, Sons of the American Revolution, and the Crescent Lodge of Masons, Pittsfield, Mass.

John Oliver Montignani (A'06, M'13) who while in New York, N. Y., made the Fraternity Club his headquarters, died of pneumonia at the home of his brother, at Woburn Green Bucks, England, May 12, 1932. Mr. Montignani was born at Edinburgh, Scotland, April 7, 1880. He entered the George Watsons College at Edinburgh in 1887 and in 1895 was graduated from the commercial division. The period 1895–9 was spent in study on electrical subjects, and in conjunction with this academic work he was receiving practical training in the engineering field under a 5 years' indenture with the firm of James Milne and Son, Limited, at Milton House Works, Edinburgh. This course was completed in 1901 and Mr. Montignani undertook a special study of electric railway engineering, coming to the United States in the fall of 1902, to follow up this line of endeavor. Upon arrival here he went to work in the experimental department of the Consolidated Car Heating Company of Albany, N. Y., and until June 1903 was employed in its car lighting system. He then left to enter the employ of the Rochester Railway Company, at Rochester, N. Y., where he was employed as assistant engineer. Four years were spent in the design, supervision, and installation of transmission lines, general overhead construction, and substation equipment; for 4 years more he was engineer of electrical distribution; another 4 years were spent as assistant engineer upon New York State railways. Subsequently he was made division superintendent of the Rochester Railway and Light Company at Rochester, N. Y., and in 1926 became assistant electrical engineer of the Westchester Lighting Company at Yonkers, N. Y., a position which he continued to fill over a period of several years. In 1930 he was made engineer of electrical transmission for Stevens and Wood, Inc., New York, N. Y.

Harold Seaburg (A'24, M'29) chief electrical engineer of the United Fruit Company, Banes Division, Oriente, Cuba, died March 13, 1932, after a week's illness with pneumonia. Mr. Seaburg was a native of Tranas, Sweden (Nov. 27, 1897), and completed both grade school and technical college in an electrical engineering course, at Orebro, Sweden. In 1918 he became a draftsman of the Swedish General Electric Company, at Vesteras, Sweden, and 2 years later took up the duties of assistant electrical engineer in addition to his work as a draftsman with the Star Electric Motor Company at Newark, N. J. In 1922 as draftsman he joined the power division of the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., and the following year became a draftsman in the engineering department of the New York Edison Company, New York, N. Y. As assistant electrical engineer of the Havana Central Railroad Company, Cuba, he detailed the layout, installation, and operation of the main switchboard equipment in Melones power plant of this company, and in its 3 railway and lighting substations. He also was largely responsible for the installation of the central power plant in the city of Havana, Cuba. As chief electrical engineer of the United Fruit Company, Banes, Oriente, Cuba, he was in charge of all electrical equipment in the electrified sugar central which has a normal annual output of about 700,000 bags.

George Crisson (A'09, M'30) who has been with the American Telephone and Telegraph Company, New York, N. Y., since 1910, died at the Presbyterian Hospital in Newark, N. J., May 22, 1932. Mr. Crisson was born at Astoria, N. Y., October 2, 1885. His M.E. degree was conferred upon him by Stevens Institute of Technology, Hoboken, N. J., to which he returned as an instructor in electrical engineering in 1906. In this capacity he continued until 1910, the year of his joining the American Telephone and Telegraph Company for the design and testing of fittings and structures used in outside plant construction. In 1914 he changed over to development work on transmission problems, principally in the application of telephone repeaters to the improvement of long distance transmission, but including related matters, such as amplifiers for public speaking systems, voice-operated apparatus for the suppression of echoes and singing on long distance wire circuits, the transatlantic radiotelephone circuits, and proposed transatlantic cable. Several patents in this field were the results of work, and were incorporated in the company's communication system and specifically in the dial telephone.

William Franklin Yeager (A'27) engineer of the United Engineers and Constructors, Inc., Philadelphia, Pa., died February 13, 1932. Philadelphia was his place of birth, September 18, 1879; there also he received the major portion of his grade schooling, going later to the Williamson Free School of Mechanical Trades, Williamson, Pa., from which he was graduated as an electrical machinist in 1899; Mr. Yeager's experience in the commercial world was broadly diversified, including much of design, construction, and machine work in other than electrical fields. For H. S. Farquhar, Philadelphia engineer, he did detailed structural and mechanical calculation, and electrical and mechanical investigation of plant equipment at the Jefferson Hospital, Philadelphia, and investigation and report on electrical machinery, testing of generators, indicator tests on engines, and coal and water rating tests on boilers at the Rittenhouse Club, Philadelphia. For Day and Zimmermann, Inc., later the Day and Zimmermann Engineering and Construction Company, he functioned as engineer and chief draftsman, chief structural engineer, and finally consulting engineer, spending 7 years in the company's employ. During the period 1918–1920 as design engineer for Day and Zimmermann his work was the supervision of engineers, under the direction of the Construction Division of the U.S. Army, on the Philadelphia Quartermaster Terminal and the Motor Transport headquarters. The supervision of design for a power plant at McAllister, Okla., also was Mr. Yeager's work, as was the investigation and report on terminal warehousing and motor and rail facilities on Long Island, N. Y. Most of his latter work was investigation and report for his company on development and possible betterment of many large activities.

Harold Bailey Brigham (A'31) engineer of the Byllesby Engineering and Management Corporation, with the Oklahoma Gas and Electric Company, Oklahoma City, Okla., died April 10, 1932 in that city. He was born at Belle Plain, Kans., July 23, 1899, and won his degree of B.S. in E.E. at the University of Oklahoma in 1923. After graduation he joined the distribution engineering department of the Oklahoma Gas and Electric Company, his affiliation with this company representing rapid progress through its various departments; extension engineer in the contracts department; division engineer; back to the distribution engineering department; in the office of the general superintendent; assistant distribution engineer in 1928. That same year he became a member of the Oklahoma City auxiliary force of engineering of the Byllesby Engineering and Management Corporation, the organization with which he was identified at the time of his death.

Thomas McLean (A'11) who for many years served the Los Angeles Gas and Electric Corporation, Los Angeles, Calif.; in varying capacities of operator and as foreman of substation operators, died Friday, May 13, 1932. A native of Long Island, N. Y., Mr. McLean in 1895 at the age of 17 engaged with the Brooklyn Edison Company, Brooklyn, N. Y., starting as a trimmer and advancing to generating station operator, the position which he held until he resigned in 1910. Thence he went directly to Los Angeles and joined the Los Angeles Gas and Electric Corporation. Here he was a meter tester, a work which he continued over a period of years. In 1923 he assumed the title of operator, and a year or so later was made foreman of substation operation.

Henry Worrell Beers (A'25) of the H. W. Beers Company, Mexico, D. F., Mex., died there the 10th of April 1932. Although for years a resident of Mexico and the head of an established electrical supply business there, Mr. Beers was a native of the United States, having been born in Columbus, Miss., December 31, 1876. Before founding his own business, he worked for the Mexican Light and Power Company, Mexico City, over a long period of years.

Jin Tachihara (A'98) manager of the Mitsubishi Electric Company, Tokyo, Japan, and prominent in the engineering profession of that country, died December 16, 1931. At the time of his becoming a member of the A.I.E.E., Mr. Tachihara was affiliated with the General Electric Company of Schenectady, N. Y.

# Local Meetings

## Oklahoma City Section Meets With Branches

The annual joint meeting of the Oklahoma City Section and the student Branches at the Oklahoma A. & M. College and the Univ. of Oklahoma, was held at the latter school on May 16, 1932. Students of the 2 schools presented the following technical papers:

**Morning**

Measurement of Distortion, by J. L. Lisk, Univ. of Okla.

Manufacture and Use of Tungsten Carbide Diamond Substitutes: Electrical and Other Considerations, by G. L. Keyser, Okla. A. & M. Col.

Calculating Tables for Distributed Loads on Transmission and Distribution Circuits, by F. H. Cullison, Univ. of Okla.

Economics of Rural Line Distribution, by B. E. Lowe, Okla. A. & M. Col.

A luncheon was held at the Student Union Building, followed by a short tour of inspection through the various engineering buildings.

**Afternoon**

Voltage Regulating Transformers and Their Application, by C. A. Ludwick, Univ. of Okla.

Jet Wave Rectifiers, by L. S. Cox, Okla. A. & M. Col.

Class B Amplifiers, by J. L. Callahan, Univ. of Okla.

Control of Gyroscope Stabilizers for Prevention of Rolling of Heavy Sea-Going Vessels, by P. O. Bobo, Okla. A. & M. Col.

Prizes for the above papers were awarded as follows:

First prize ($15) Bernard E. Lowe, Oklahoma A. & M. Col.

Second prize ($10) Charles A. Ludwick, Univ. of Okla.

Third prize ($5) Powell O. Bobo, Okla. A. & M. Col.

After the student meeting, the Oklahoma City Section held a short business meeting and the new officers were announced as indicated: E. B. Jennings, chmn.; R. F. Danner, vice-chmn.; C. E. Bathe, secy.-treas. The attendance was 80.

# Past Section Meetings

**Akron**

Banquet. Election of officers: A. P. Regal, chmn.; W. H. Tucker, secy. Human Engineering, by Dean F. E. Ayers, Univ. of Akron. May 10. Att. 47.

**Baltimore**

Electric Shock, by Dr. W. B. Kouwenhoven, Johns Hopkins Univ., vice-pres. A.I.E.E. Election of officers: J. Wells, chmn.; L. G. Smith, vice-chmn.; J. L. D. Speer, secy.-treas. May 27. Att. 37.

**Cleveland**

Mystery and Musical Telepathy, by Mr. and Mrs. DeJen. Election of officers: J. M. Smith, chmn.; S. B. Taylor, secy.-treas. May 26. Att. 110.

**Connecticut**

Some Practical Problems in the Operation of High Tension Network Systems, by C. W. Mayott, Connecticut Valley Pwr. Exchange. April 14. Att. 60.

**Dallas**

Finances, by J. E. Owens, Republic Natl. Bank and Trust Co. Election of officers: H. K. Handley, chmn.; W. B. Folline, secy. May 16. Att. 58.

**Denver**

Election of officers: W. D. Hardaway, chmn.; A. W. Ainsworth, vice-chmn.; N. R. Love, secy.-treas. May 5. Att. 14.

Moving pictures presented under the auspices of the Colorado Museum of Natural History. Dinner. June 1. Att. 38.

**Detroit-Ann Arbor**

Adventures in Science, by Oliver Ajer, Genl. Elec. Co. Demonstrations. May 17. Att. 325.

**Erie**

Lighter Than Air Craft, by V. R. Jacobs, Goodyear Tire & Rubber Co. May 17. Att. 175.

**Iowa**

Election of officers: L. F. Wood, chmn.; B. S. Willis, secy.-treas. May 24. Att. 11.

**Kansas City**

Banquet. The Requirements for Business Recovery, by Prof. J. H. Taggart, Univ. of Kansas. Election of officers: G. O. Brown, chmn.; E. W. Harvey, secy.-treas. May 26. Att. 53.

**Lehigh Valley**

Aeroplane and Ship to Shore Communication, by L. Espenschied, American Tel. & Tel. Co. Feb. 12. Att. 104.

Recent Advances in Engineering as Applied to Industry and the Home, by C. K. Lee, Westinghouse Elec. & Mfg. Co. Illus. April 22. Att. 117.

High Voltage Cables—Their Manufacture and Application, by D. M. Simmons, Genl. Cable Corp. Election of officers: J. G. Charest, chmn.; W. A. Skinner, secy. May 13. Att. 90.

**Los Angeles**

Boat trip around the Los Angeles harbor and dinner. May 14. Att. 60.

**Louisville**

New Dial Telephone Equipment, by H. C. Walker, Southern Bell Tel. & Tel. Co. Demonstrations. Inspection of the new telephone building and equipment. May 13. Att. 87.

**Lynn**

Inspection trip of the East Boston Airport of the Curtis-Wright Flying Service. April 23. Att. 300.

**Madison**

Governors and the Governing of Prime Movers, by Albert Kalin, Woodward Governor Co. Inspection trip through the plant of the Woodward Governor Co. May 21. Att. 57.

**Mexico**

Comparison Between Group Drive and Individual Drive in Shops, by L. Castro, Jr., Natl. Railways of Mexico. May 19. Att. 30.

**Milwaukee**

Modern Manchuria, by Prof. H. E. Babbitt, Univ. of Ill. Joint meeting with Engrs. Soc. of Milwaukee. April 20. Att. 300.

Educational Future of the College of Engineering, U. of Wis. by Dean F. E. Turneaure; Reminiscences of an Engineer, by Prof. D. W. Mead; Plan Development for the College of Engineering, by Arthur Peabody; The Need of a Two Year Course in Engineering, by Arthur Simon. F. H. Dorner presented a tablet with pictures donated to the University on the occasion of the dedication of the new mechanical engineering building. Dinner. May 27. Att. 250.

Recent Applications of the Vacuum Tube in Industry, by R. E. Welton, Genl. Elec. Co. Election of officers: W. F. Lent, chmn.; C. D. Brown, secy.-treas. June 1. Att. 60.

**Montana**

Commutation in Generators and Motors Used in Mine Hoists, by A. W. Boyer; Electrical Properties of Hardened Copper, by H. Lambdin and A. J. Hill, students, Montana State Col. Election of officers: J. A. Thaler, chmn.; H. Dale Cline, secy. June 4. Att. 23.

**Nebraska**

The Engineer in Society and Industry, by T. W. McCullough, Omaha Bee News. Joint meeting with Univ. of Nebraska Branch. May 11. Att. 106.

Short talks by Professors Caldwell and Brookman, Univ. of So. Dakota, P. H. Patton, vice-pres. A.I.E.E., and John Gibb, pres. Omaha Engrs.' Club. Joint meeting with Univ. of So. Dakota Branch. May 17. Att. 25.

**New York**

Lighting Requirements for Publishing Operation, by E. Whitehorne, McGraw-Hill Co., Raymond Hood, and Fouilhoux, and D. Wood, Lockwood Greene Engrs., Inc. May 12. Att. 150.

**Niagara Frontier**

Ladies' night. May 20. Att. 75.

**Philadelphia**

Transoceanic Telephony, by H. S. Osborne, Am. Tel. & Tel. Co. Election of officers: Prof. L. Fussell, chmn.; J. L. MacBurney, secy.; E. C. Drew, treas. May 9. Att. 150.

**St. Louis**

General descriptions of the transmission lines from the Bagnell Station were given by L. T. Byers, Stanley Stokes, and H. E. Gove of the Union Elec. Lt. & Pwr. Co., and F. G. Dana and G. W. Couch of Stone & Webster Engg. Corp. May 18. Att. 98.

**Seattle**

The Use of Electricity in the Electrochemical Industry, by L. Supovi, Hooker Electrochemical Co. Election of officers: A. F. Darland, chmn.; G. L. Hoard, vice-chmn.; K. L. Howe, secy.-treas. May 17. Att. 66.

**Sharon**

The Use of Aluminum in the U.S.S. Akron, by G. O. Hoglund, Aluminum Co. of America. Moving pictures. May 31. Att. 95.

**Spokane**

Steam Power Plant Developments Including Mercury Boilers and Turbines, by W. F. Hynes, Genl. Elec. Co. April 22. Att. 38.

**Syracuse**

Steam Electric Power Plants, by I. E. Moultrop, Edison Elec. Ill. Co. of Boston, vice-pres. A.I.E.E. March 7. Att. 38.

International Engineering Congress, by Dr. C. E. Skinner, Westinghouse Elec. & Mfg. Co., pres. A.I.E.E. Joint meeting with Technology Club of Syracuse. May 9. Att. 225.

# Past Branch Meetings

**University of Akron**

The Firestone Power Plant, by W. J. Boyd, student. F. J. Marcinkoski, student, gave a demonstration of resuscitation. Election of officers: F. J. Marcinkoski, chmn.; R. A. Ries, secy. May 13. Att. 10.

**University of Arizona**

The Deion Grid Circuit Breaker, by B. Watkins, student. April 29. Att. 8.

Discussion. April 22. Att. 8.

Film—"Dynamic America." May 6. Att. 27.

Some Thoughts on Technical Education and The Vernier Slot Effect, by Prof. J. C. Clark, counselor. May 13. Att. 8.

Research on Dielectric Losses in Insulating Materials, by F. A. Decker. May 20. Att. 10.

The Colorado River and the Boulder Canyon Dam, by O. H. Polk. Election of officers: Bruce Watkins, chmn.; Jack Jones, vice-chmn.; H. Stewart, secy.-treas. May 26. Att. 8.

**University of Arkansas**

Plotting Magnetic Fields, by H. G. Thomasson, student; The Tesla Coil, by C. L. Mowery, student; Rural Electrification, by H. H. Lewis, student; Rates, by F. L. McDonald, student. May 2. Att. 25.

Carrier Currents, by W. F. Stewart; Long Distance Communication, by L. C. Wasson; Armature Reaction, by W. C. Whitfield; Hydroelectric Dams, by E. E. Cato; Transoceanic Cables, by W. D. Thornberry; Cathode Ray Oscillograph, by R. E. Cope, all students. May 16. Att. 24.

**Brooklyn Polytechnic Institute**

Regenerative Braking on Direct-Current Railways, by Charles Pedersen, student; Use of Thyrite in the Arms of a Wheatstone Bridge, by F. Rae, student; A Brief History of Photoelectricity, by Frank Maloney, student. Election of officers: I. Andreasen, chmn.; H. Hoffman, vice-pres.; Robert Hampshire, secy.; Charles Pedersen, treas. May 18. Att. 39.

**Bucknell University**

Film—"Dynamic America." Lecture on the photoelectric cell. May 17. Att. 125.

**California Institute of Technology**

Transpacific Radio Communication, by F. H. Kroger, R. C. A. Motion pictures. May 24. Att. 35.

**University of California**

Election of officers: Wm. D. Hudgins, chmn.; V. Welge, vice-chmn.; L. R. Rockholt, secy.; H. Lorenzen, treas. April 27. Att. 11.

**University of Cincinnati**

Joint meeting with the Cincinnati Section with papers by students as follows: A Laboratory Arc Furnace, by E. J. Emmerling; Measurement of Modulation, by J. Epstein; Constant Radio Frequency, by A. C. Herweh; Measurement of Radiation, by C. L. Ramsey; An Electric Organ, by W. E. Kock. May 12. Att. 80.

**Clemson Agricultural College**

Inspection trip to the hydroelectric plants of the Georgia Pwr. Co. April 18. Att. 85.

Election of officers: C. P. Walker, chmn.; T. M. Watson, vice-chmn.; W. F. Tribble, secy.-treas. May 12. Att. 20.

**University of Colorado**

A New Method for Measuring Angular Displacements in Synchronous Machines, by L. L. Mundell and W. C. Spear, students. May 18. Att. 35.

**Cornell University**

Teletypewriter Systems, by B. K. Boyce, N. Y. Tel. Co. April 22.

**University of Denver**

Election of officers: Paul Barth, chmn.; F. A. Dow, vice-chmn.; Carl Hedberg, secy.-treas. May 11. Att. 12.

**University of Detroit**

Banquet. History of Electric Lighting in Detroit, by J. W. Bishop, Ford Motor Co. Election of officers: J. A. Schenk, chmn.; A. Manning, vice-chmn.; Ralph Martin, secy.; Frank Belch, treas. June 1. Att. 33.

**Drexel Institute**

The Development of Long and Short Wave Transmitters, by C. E. Keener, student. May 4. Att. 21.

Election of officers: F. P. States, chmn.; R. W. King, vice-chmn.; F. A. Hipple, secy.; F. E. Seaman, treas. May 18. Att. 15.

**Duke University**

Banquet. Election of officers: Tom Garrett, chmn.; John Womack, vice-chmn.; H. W. Atkinson, secy. May 12. Att. 16.

**University of Florida**

Public Address Systems, by George Haug, student; Problems Encountered in Taking a Transmission Line Inventory, by Craig Huffer, student. May 18. Att. 12.

**Georgia School of Technology**

Inspection trip through the Fox Theater. May 2. Att. 29.

Election of officers: F. T. Meiere, chmn.; E. C. Wagner, vice-chmn.; W. W. Ensminger, secy.-treas. May 16. Att. 53.

**Harvard University**

Some Phases of Institute Work, by I. E. Moultrop, Edison Elec. Ill. Co. of Boston, vice-pres. A.I.E.E. Election of officers; F. W. Roberts, chmn.; R. H. Packard, secy.; R. A. Ward, senior rep.; S. Smith, vice-chmn. May 23. Att. 16.

**University of Idaho**

Telephone Service, by Mr. Hadley, Interstate Telephone Co. Banquet. May 3. Att. 25.

Election of officers: H. R. McBirney, chmn.; Wm. Clagett, vice-chmn.; Fred Quist, secy.-treas. May 13. Att. 18.

**University of Illinois**

Election of officers: J. C. Wheeler, chmn.; P. S. Bickenbach, vice-chmn.; D. Bergelis, secy.; H. W. Bieritz, treas. May 11. Att. 19.

Dinner. May 15. Att. 16.

The Inversion of D-C. Into A-C. by Use of the Thyratron, by Dr. Reich. May 17. Att. 60.

**Iowa State College**

Election of officers: Glenn Lyshoj, chmn.; R. Allbright, vice-chmn.; Robert Doonan, secy.; Truman Eppert, treas. May 11. Att. 30.

**Kansas State College**

Conditions in Russia, by C. R. Bradley. Joint meeting with Univ. of Kansas Branch. May 5.

Giant Radio Tubes, by A. C. Hebert, student. May 12. Att. 57.

Airship Mooring Masts, by A. B. Niemoller, student; New Developments in Photoelectric Cells, by D. A. Bly, student. May 12. Att. 30.

Election of officers: S. R. Mudge, pres.; G. D. Ferguson, vice-pres.; B. E. Hammond, recording secy.; J. P. Kesler, treas.; A. E. Paige, marshall. May 19.

**University of Kansas**

Election of officers: R. C. Jackson, chmn.; R. C. Ayres, vice-chmn.; John Doolittle, secy.; Warren Boast, treas. May 19. Att. 36.

**University of Kentucky**

Modern Methods for Oil Well Drilling, by O. T. Koppius. April 27. Att. 36.

**University of Louisville**

Sir Isaac Newton, by Harold Walter, student. Election of officers: C. B. Eldridge, chmn.; H. F. Walter, vice-chmn.; Frank Neuhouser, secy.-treas. May 20. Att. 20.

**Marquette University**

Business meeting. May 5. Att. 25.

**Michigan State College**

Chicago Radio Show, by R. T. Thompson, student. May 10. Att. 17.

**University of Michigan**

Annual banquet. May 26. Att. 43.

**Milwaukee, School of Engineering of**

Some Aspects of the Public Utility Situation in Wisconsin, by G. W. Post, Milwaukee Elec. Ry. and Lt. Co. Illus. May 11. Att. 112.

**University of Missouri**

Election of officers: A. E. Coffman, chmn.; R. C. Cunningham, secy.-treas. May 12. Att. 17.

**Montana State College**

Milestones in Electrical Progress, by Prof. C. F. Bowman. May 19. Att. 66.

Electrical Properties of Hardened Copper, by A. Hill and H. Lambdin, students. May 26. Att. 88.

**University of Nebraska**

Demonstration of telephone equipment by S. P. Grace, vice-pres., Bell Tel. Labs., Inc. May 11. Att. 94.

Helmholtz's Law and Its Application to Television, by R. Brackett. May 18. Att. 12.

**University of Nevada**

Development of a Course of Study in Illumination, by L. G. Gianini, Genl. Elec. Co. March 17. Att. 34.

Election of officers: Milton Murphy, chmn.; Raymond Robinson, vice-chmn.; Harry Dunseath, secy.-treas. April 25. Att. 8.

**Newark College of Engineering**

Electric Ranges, by Prof. A. A. Mims. May 16. Att. 34.

**North Carolina State College**

Subjects for Fall Convention Papers, by J. L. Ponzer, student; General Report on Fall Meetings, by G. E. Ritchie, student. May 17. Att. 26.

**University of North Dakota**

Facsimile Transmission as Used in Navy Radio Sets, by John Gilhooley. May 4. Att. 14.

**University of Notre Dame**

Commercial Engineering or Engineering Economics, by Mr. DeQuine; Relativity, by J. A. Caparo, counselor. Election of officers: F. J. Lennartz, chmn.; Wm. H. Fromm, vice-chmn.; A. V. Alvino, treas.; J. K. Carnes, secy. May 10. Att. 62.

**Ohio University**

Election of officers: J. F. Hoskinson, chmn.; Wm. B. Cooper, vice-chmn.; E. H. Pryor, secy.-treas. May 11. Att. 37.

**Oklahoma A. & M. College**

Business meeting. May 9. Att. 10.

**Oregon State College**

Election of officers: John Mather, pres.; Bob Blasen, vice-pres.; L. Pennell, secy ; G. Manke, treas. May 2. Att. 20.

Development and Progress of Steam Power, by W. F. Hynes, Genl. Elec. Co. Illus. May 5. Att. 47.

A Modern Radio Test Kit, by H. Beckendorf, student; Directional Antennae and Their Operation, by M. Kofoid, student. May 16. Att. 30.

Joint meeting with the Portland Section at which the following papers were presented by students: Steam vs. Electric Drive for Sawmill Operation, by E. A. Buckhorn; A New Wattmeter for Communication Circuits, by K. R. Eldredge; Progress in the Electrical Measurement of Sound Absorption, by F. A. Everest; An Investigation of Field Strength Variations at Broadcast Frequencies, by G. S. Feikert. May 21. Att. 125.

**University of Pittsburgh**

Economic Value of Research, by Mr. Grondahl, Union Switch & Signal Co. May 5. Att. 100.

A New Type of Automobile Tire, by D. E. Trieber, student. May 12. Att. 100.

**Rensselaer Polytechnic Institute**

Development of Teletypewriter Systems, by P. D. Bryan, N. Y. Telephone Co. Election of officers: R. E. McAdam, chmn.; J. J. Korkoss, vice-chmn.; E. W. Knight, secy.-treas. April 19. Att. 305.

**Rose Polytechnic Institute**

Election of officers: J. C. Dalrymple, chmn.; G. T. Lautenschlager, secy. May 25. Att. 17.

**South Dakota State School of Mines**

The Western Union Program, by Mr. Blewitt, Western Union Telegraph Co. May 10. Att. 32.

**University of South Carolina**

Distribtuion of Power in South Carolina, by Senator T. B. Pearce. Banquet. May 5. Att. 30.

Story of the Motor Pump, by W. R. Humphlett; Electrical Therapeutics in Industry, by D. W. Cardwell; Short Wave Radio, by A. W. Obenschain; Some Marvels of the Universe, by W. S. Smith; Baltimore and Ohio Centralizes Traffic Control, by J. D. Martin, all students. May 12. Att. 36.

**University of Southern California**

Mercury Arc Rectifiers, by Mr. Fewcuey, Genl. Elec. Co. May 11. Att. 27.

Election of officers: R. R. Moore, chmn.; H. A. Peterman, vice-chmn.; Mr. Bailey, secy.; H. West, treas. May 18. Att. 33.

The Future of the Engineer, by Carl Heinze, Los Angeles Bureau of Water and Pwr. May 19. Att. 35.

**Southern Methodist University**

Election of officers: Porter Lindsley, Jr., chmn.; M. P. Jones, vice-chmn.; N. K. Read, secy.-treas. May 18. Att. 11.

Social gathering. May 28.

**Texas A. & M. College**

Discussion. May 19. Att. 50.

**University of Texas**

Electric Rates in Texas, by L. M. Curry, student. May 12. Att. 15.

Election of officers: Frank Sperry, pres.; J. R. Cutler, vice-pres.; Wm. Garrett, secy.-treas.; L. Baker, corres. secy. May 14. Att. 15.

**University of Utah**

A Stroboscopic Device for Studying Rotary Motion, by W. S. Nishiyama and K. M. Neilson, students. Demonstrations. May 2[illegible]. Att. 43.

**Virginia Polytechnic Institute**

Life and Works of Thomas A. Edison, by P. H. Cross. Illus. May 12. Att. 46.

**University of Virginia**

Election of officers: T. J. LoCascio, pres.; C. E. Stahl, vice-pres.; G. K. Carter, secy.; J. W. Bowles, treas. May 23. Att. 11.

**University of Washington**

Modern Switchgear Equipment, by K. L. Howe, Westinghouse Elec. & Mfg. Co. Election of officers: W. Ryland Hill, chmn.; Earl Hathaway, vice-chmn.; Archie Adams, secy.-treas. May 12. Att. 14.

Cushman Power Development, by J. V. Congwer, Engr., City of Tacoma. May 19. Att. 31.

**Washington State College**

Discussion. May 13. Att. 9.

Election of officers: Paul Hand, pres.; A. McDougald, vice-pres.; Dick Wilson, secy.; G. Martinson, treas. May 24. Att. 17.

**Washington University**

Election of officers: Mr. Keiser, chmn.; Mr. Mendel, secy.-treas.; Mr. Maull, vice-pres. May 19. Att. 25.

**Worcester Polytechnic Institute**

Testing of High Voltage Transformers, by A. M. Tarbox, Westinghouse Elec. & Mfg. Co. Election of officers: W. E. Bass, chmn.; F. M. Potter, vice-chmn.; C. S. Brewer, secy.; H. A. Hammer, treas. April 25. Att. 32.

# Employment Notes

## Of the Engineering Societies Employment Service

## Men Available

### Construction

FOREMAN OR CHIEF ELECTRICIAN, expert armature winding, motor repairs, and trouble. Install wiring systems for light and power. Extensive practical experience. D-657.

E.E. GRAD., 1927, Univ. of Wis., 30, married, 6 yr. experience in transformer, relay and meter testing, switchboard installations, outdoor substation construction and drafting, industrial pwr. and lighting layouts, inspection, and estimates. Location, Middle West preferred, others considered. D-1071.

GRAD. E.E., 29; 5 yr. supervisory construction, design, estimating and field engg. experience on super-power plants and substations; 4 yr. industrial pwr. plant operation. Electrical construction and maintenance experience; railway electrification construction experience. C-4428.

GRAD. E.E., 1927, single. 3 yr. construction and engg. work on ry. signals, train control, and small power plants. 2 yr. test dept. of large pwr. company. Desires connection with construction, industrial or utility concern or as instructor in mathematics or E.E. subjects. Available at once. Location, immaterial. C-6439.

### Design and Development

E.E. GRAD., 29, single, 5 yr. experience including 6 months testing a-c., d-c. machines, $4^1/_2$ yr. design 5 to 2,000 hp. a-c. and d-c, motors for industrial and special applications. Thoroughly familiar with motor quotations, estimates and applications. Desires position with utility, mfg. or construction firm. Location, U.S. Available immediately. D-944.

DISTRIBUTION ENGR., MFG. ENGR.: E.E. grad., 27, married, 6 yr. experience with large elec. mfg. company, desires position as transformer design engr., mfg. engr., or as elec. engr. for utility or holding company. Available immediately. D-963.

ENGR., electrical-welding: 13 yr. experience design and application resistance welding equip. 4 yr. full charge design and research. Considerable experience on arc welders. Knows shop practise under mass production conditions. Also had wide experience as sales engr. Held 2 positions as sales mgr. and has nation-wide dealer contacts. D-994.

DESIGNING ENGR., E.E. grad., 32, married, 8 yr. experience in designing and selling instrument and dry type distribution transformers. Desires employment with utility or mfg. concern, selling or engg. Available immediately. Location, immaterial. Best references. D-1015.

E.E. GRAD., 28, married, desires position in design and development or teaching. One yr. Westinghouse Student Course; 6 months Westinghouse Design School; $1^1/_2$ yr. design of fractional hp. motors; $2^1/_2$ yr. design of industrial motors. Available at once. Location, U.S. C-5051.

ELEC.-MECH. ENGR., 30, married, college grad. with usual abilities for elec. relay circuits (autom. teleph., control, alarm systems, signaling) resourceful mech. designer on small apparatus, 5 yr. engg. experience. Available immediately. Location, immaterial. C-8373.

E.E. GRAD., 1928, Rensselaer Poly. Inst., 28 yr. single, 4 yr. experience in genl. elec. pwr. plant and substation design and right-of-way and operating budget work with utility. Desires to enter such a field as plant engg. or industrial or economic planning. Available at once. D-1061.

GRAD. E.E., 29, single, 7 yr. experience designing and installing elec. and mech. equip. for large steel company. Highest references. Location, immaterial. Available on short notice. D-1037.

MECH.-ELEC. ENGR., 32, 4 yr. Cornell design instructor; 5 yr. Allis-Chalmers design; liberal shop experience; 5 yr. cooperative apprenticeship. Will consider anything, anywhere, now available. Salary open. D-122.

### Draftsmen

E.E., 1931, 24, married. Experience: Drafting, grad. of 5 months training in large utility, 6 months in utility research dept. Interested in illumination, substation, or distribution. Available at once, and in need of work. Any location. D-1041.

### Executives

MECH. & ELEC. ENGR., grad., married, 20 yr. experience in design, construction, and operation of mill and smelter in the ferrous and nonferrous industries, with excellent record in plant improvement and lowering production costs, desires responsible position with industrial plant engg. firm or sales office. B-7343.

SUPT. ERECTOR, 28, paper mill and printing mchy., experimental and developing automatic mchy., 7 yr., has legal training; executive and management experience, inspecting and auditing, thoroughly familiar with elec. meter lab. Wants any position to prove his capabilities. D-965.

TECH. GRAD., 33, married. Eleven yr. experience covering all branches of elec. measurements in lab. of large mfg. company. Desires position with utility in meter or transmission and distribution dept. Available on short notice. Location in East preferred. D-981.

EXEC. OR CONSULTING ENGR., mech. and elec., 43, American, college education. Past 3 yr. with prominent engg. organization correlating design engg. work for large central station and industrial pwr. plant projects. Previous experience included building, testing, and operating similar plants. Exceptionally broad experience. Available July 1. D-986.

ASSOC. ELEC. ENGR., 38, married, tech. education, 9 yr. with utility as distribution engr., estimating, inspection, underground construction, contact man, developed plans and records division; 6 yr. research and development on protective devices. Available immediately, location, immaterial. C-8958.

ELEC. ENGR., 34. Ten yr. experience covering design, cost estimating and equipment specifications of pwr. plants, copper refineries, indoor, and outdoor substations, transmission lines, and industrial work. Also 1 yr. experience as asst. research with cable company. C-5473.

E.E.—M.E. GRAD., married, 20 yr. experience, desires connection, engr., asst. exec. where efficient use of pwr. and plant is needed; also teaching. Experienced, design of plant; modern design, manufacture, installation of equipment; plant maintenance; electrical, equipment layouts. Special training, experience, metallurgy, concrete, elec. arc welding, building construction, specifications, business mgmt., sales. C-4519.

E.E., 10 yr. experience. Executive ability. Seven yr. operation and maintenance interconnected pwr. system; relay and communication problems; design and installation automatic equipments. Three yr. with large mgmt. company, including 1½ yr. in Mexico on economic studies, generation and transmission projects, and 1½ yr. electrolysis investigations domestic natural gas lines. D-1003.

EXEC. OR ASST., 18 yr. broad experience in utility, mfg., industrial surveys, and mgmt. problems. Through proper application of engg. analysis and principles, can effect economies in operation and control. Capable organizer. Profitable asst. to busy exec. Salary secondary to opportunity. B-9122.

EXEC. ASST. available, 12 yr. utility experience. Grad. E.E., 37. Appraisal work of pwr. plants, substations, transmission and distribution systems, rate investigations covering industrial service, residential and commercial, cost studies, statistical research, operation in plant, equipment and lines. G.E. test course. B-9782.

E.E., married, E.E., M.E. 22 yr. experience, designing, construction pwr. plants, substations, transmission, distribution systems, industrial plants. 3 yr. charge purchasing engg. equip., foreign interests. 3 yr. executive experience charge engg. dept. large utility syndicate. English, German, Russian, Armenian languages. Available immediately. D-84.

GRAD. E.E., 32, 10 yr. experience, of which over one-half was spent with large utility in engg. and supervisory work and the remainder with mfr. of high tension switching equip. as assistant gen mgr. Available on short notice. Location, immaterial. D-745.

ASSOC. A.I.E.E., B.S. in E.E. Iowa State College, 1929, 32, single, worked way through school, 3 yr. Westinghouse insp. and test, including c.c. regulators, c.l. reactors, dimmer reactors, instrument transf., distribution and power transf. a-c. welding outfits, misc. equipment. Interested in supervision, developments, application engineering, rural electrification. References. Location, immaterial. Available immediately. D-1081.

E.E., 33, married, desires position, mfgr. of radio or public address systems, broadcasting station, or carrier dept. of elec. pwr. co. 4 yr. design, construction, operation, testing of equipment for electric pwr. stations. 6 yr. installation, wiring testing radio broadcast, telephone and telegraph repeaters, and carrier equip. Excellent references. D-733.

E.E. wants position. Wide experience in elec. field, engg., mfg., sales, erection and operation of storage batteries. E.E. Grad. from Mass. Inst. of Tech. C-4109.

GRAD. ENGR., 35, with 10 yr. experience in the engg., operating, and executive depts. of a utility, desires position as jr. exec. or office mgr. in a mfg. concern or utility. Speaks Spanish and has fair knowledge of acctg. B-2470.

### Instruction

GRAD. E.E., 35, married, B.S. in E.E. at M.I.T. 1920. Entire experience since then in E.E. teaching and E.E. industrial work. Good ability and personality. Desires work in E.E. teaching. Salary open. C-2826.

E.E. GRAD., 1925, Ohio State, 32, married, experience; pwr. plant and substation operation and maintenance, distribution (a-c. and d-c.), relay engg., pwr. plant and substation design and supervisory construction experience with contractor, high school instructor. Desires position with future. Available immediately. D-996.

E.E. GRAD., 26, single, desires position in design and development or teaching. Westinghouse student course. Westinghouse design school. Rectifier design. Available at once. Location, immaterial. D-988.

E.E. DESIGNER, 31, married, 4 yr. experience in construction, 3 yr. experience in design of pwr. stations, substations and industrial control, 1 yr. instructor in large univ. and 8 months Westinghouse test course, desires position in engg. office, field construction or teaching. C-5734.

GRAD. E.E., 1926, single, 29, G.E. Test Course, 5 yr. experience on proposition work and specifications as commercial engr. with large elec. manufacturing concern. Desires to enter teaching field in U.S. Electrical subjects, physics, mathematics, or English. Will be interested in opportunity for advanced study. D-1005.

INSTRUCTOR OR ASST. PROF., 38, 8 yr. instructor in E.E., radio, physics in univ.; 5 yr. commercial experience, lighting, pwr., and radio installations, research and design. At present research assoc. in physics in post grad. school of well known univ. Available for next September. C-6302.

DOCTOR OF ENGG., J.H.U., '32, 23, single. Research experience in fields of radio, a-c. and d-c. measurements and high voltage insulation studies. Desires research or engg. position, also teaching in E.E., mathematics, or physics. Location, immaterial. D-1040.

ASSOC. PROF. E.E. B.S., and E.E. deg., 42. 5 yr. teaching experience, 11 yr. design, engg. and exec. experience in radio and communication. Highest references. Available immediately. Location, immaterial. D-1062.

M.S. in E.E. and PHYSICS, 31, married, coached mathematics, physics, E.E. while undergraduate, senior math. asst., some teaching with grad. study. 6 yr. industrial motor design, research, also mfg. practise, motor control. Desires to teach E.E. primarily, charge or part charge of research; can also teach drafting, machine design. Available season 1932–33. D-980.

### Junior Engineers

E. E. GRAD., Purdue, 1931, single, 24. Seven months in training course of a large utility company. Experienced in stenographic and secretarial work. Desires position with future in mfg. concern or utility. Available at once. Location immaterial. D-437.

RECENT COLUMBIA UNIV. GRAD., B.S., 1931, E.E. in 1932; Italian born, but American citizen, desires engg. or teaching opportunity. D-894.

E.E. GRAD., 1928. Iowa State Coll., 25, single. 1½ yr. experience designing of rural lines, 1 yr. experience designing distribution city lines, 1 yr. experience handling joint contracts between elec. and telephone companies. Desires position with utility. Location, Middle West or West. Available immediately. D-978.

JUNIOR ENGR., E.E. GRAD., 31, married, B.S. 5 yr. operating and maintenance utility, 14 months Westinghouse test, 2 yr. Westinghouse motor sales dept. Good experience on motors and control. Some civil engg. experience. D-1025-321-C-2-San Francisco.

E.E. GRAD., '23, Sc.M., M.I.T. and Harvard '28; Sc.D. M.I.T. June '32, thesis in network synthesis; 38, single; 8 yr. practical experience, pwr.-business-and communication engg. Two yr. testing course. Speaks Swedish, English, German; reading knowledge French. Desires position preferably in line of communication engg. Available June 15th. Location, immaterial. D-747.

E.E. GRAD., 27, married. Design of pwr. plant, substation and pwr. transmission lines. Industrial remote control. Also broad experience on appraisals of utilities. Available immediately. Location, immaterial. D-679.

E.E. GRAD., 1932, Univ. of Nebraska, single, 22. Desires engg. work in commercial field. Available now. Location, immaterial. D-997.

MECH.-ELEC. ENGR., 1930 tech. grad., 2 yr. engg. experience manufacture of elec. wires and cables, machine shop work, also surveying and drafting work. Will consider any job or position offered. Available immediately, anywhere, at minimum living salary. Single, 26, and in need of work. D-66.

GRAD. E.E., 1929, single, 23. Fifteen months student engr. on G.E. test. Some test, drafting and switchboard construction experience before graduation. Interested in position with firm doing consulting or construction work or with utility or manufacturer. Available at once. Location, anywhere in U.S., but New England preferred. C-8028.

1931 GRAD., B.E.E. cooperative course, 25, single. Experience includes elec. maintenance, const., drafting, and laboratory work. Location, immaterial. Available at once. D-1060.

EXECUTIVES If you can possibly use an ambitious young E.E. with a B.S. from Brown Univ. who, together with tech. knowledge, combines a knack for managing and publication work your correspondence is requested. The very best references can be furnished. D-742.

RECENT M.I.T. GRAD. (S.B., S.M.), in E.E. 28, cooperative training with Stone and Webster Inc., desires opportunity with future in production or construction field. Previous business experience. D-1047.

B.S. in E.E., 1931, Armour Tech., 23, single, experience: 6 months telephone, 3 months G.E. student, 7 months utility student, speaks German well, wants work, salary secondary, location, immaterial. D-1072.

1931 GRAD. IN E.E., B.S. from Clemson Agril. College, 25, single. Desires work with utility,

## ENGINEERING SOCIETIES EMPLOYMENT SERVICE

57 Post St.
San Francisco

205 West Wacker Drive
Chicago

31 West 39th St.
New York

MAINTAINED by the national societies of civil, mining, mechanical, and electrical engineers, in cooperation with the Western Society of Engineers, Chicago, and the Engineers' Club of San Francisco. An inquiry addressed to any of the three offices will bring full information concerning the services of this bureau.

**Men Available.**—Brief announcements will be published without charge, repeated only upon specific request and after one month's interval. Names and records remain on file for three months, renewable upon request. Send announcements direct to Employment Service, 31 West 39th Street, New York, N. Y., to arrive not later than the fifteenth of the month.

**Opportunities.**—A weekly bulletin of engineering positions open is available to members of the cooperating societies at a subscription of $3 per quarter or $10 per annum, payable in advance.

**Voluntary Contributions.**—Members benefiting through this service are invited to assist in its furtherance by personal contributions made within 30 days after placement on the basis of 1.5 per cent of the first year's salary.

**Answers to Announcements.**—Address the key number indicated in each case and mail to the New York office, with an extra two-cent stamp enclosed for forwarding.

mfg. concern or construction corporation. Available immediately. Location, immaterial. D-400.

E.E. GRAD., Purdue, 1930. Single, 24. 2 yr. communication experience and training with Am. Tel. & Tel. Co., including outside line and cable construction; test room operation, carrier systems, etc., also Morse telegraphy. Not afraid of hard work. References gladly furnished. Available immediately to go anywhere. D-1075.

E.E. GRAD., 26, single, excellent physical condition. One yr. experience installation, testing telephone exchange equipment. Three yr. teaching public school. Graduate small business col. Considerable training, experience, selling. Not afraid of hard work. Interested in position requiring engineering knowledge or teaching experience. Excellent references. Correspondence invited. Location, immaterial. Available immediately. D-1076.

E.E. GRAD., B.S. in E.E., cooperative course, Drexel Inst., 1931. M.S. in E.E., M.I.T., 1932, 23, single. Two yr. experience in plant dept. of Bell Telephone Co. of Pa. Desires engg. or teaching position. Location in East preferred. Available immediately. References upon request. D-1087.

Maintenance and Operation

CONSTRUCTION AND MAINTENANCE SUPT., 37, married. Grad. E.E. Thirteen yr. experience in utility field, particularly in engg., construction and maintenance of distribution and transmission substations. Desires position with large utility with responsibility for the construction, operation, and maintenance of substations. B-2885.

E.E., 31, married, tech. school. Eleven yr. experience, C.G.E. Test 4 yr. Service-maintenance - operation - construction - hydro elec. plants, paper mill-municipal and public utility hydro-plants. Will go anywhere in Canada. D-982.

PRACTICAL ELEC. CONSTRUCTION CHIEF, 32, 14 yr. experience in elec. construction work and also maintenance work. Last 4 yr. in Latin-America. Can speak Spanish and German well. Available immediately. Location, immaterial. C-2101.

E.E. GRAD., married, 8 yr. steam plant operation and maintenance, and factory maintenance. Now unemployed. Location preferred, Middle West or Western. C-8522.

Research

DEVELOPMENT-RESEARCH ENGR., experienced in the design of apparatus in the development of railroad signaling, automatic train control, and centralized traffic control systems, telephone and telegraph systems for commercial use and in connection with train dispatching. Also in making mathematical studies and theoretical investigations. D-995.

MEASUREMENT AND CONTROL SPECIALIST seeks connection with commercial lab., utility or mfr., in capacity of developing or investigating engr. or consultant. Wide and extensive experience with all types of elec. instruments, precision measurement, standardization, and automatic control. Also experienced in pyrometry and pneumatic control. B-7245.

E.E. GRAD., Carnegie Inst. 1921. Graduate work, Carnegie Inst., Univ. of Pittsburgh, 34, married. Experience, telephone switchboard installation, railway appraisal, power plant operation. Two yr. general development lab., Western Elec. Co. Nine yr. research dept., Union Switch & Signal Company doing development work on train control, copper oxide rectifiers. Location preferred, Pittsburgh. D-1031.

Sales

SALES ENGR., grad. E.E. with excellent background of both sales and advertising, desires connection with mfr. Location, Middle West preferred. Experience in industrial advertising in addition to engineering and selling of elec. equip. Excellent references. Age 33, married. B-8614.

SALES ENGR., 40, tech. grad., single, 20 yr. experience selling elec. equip. for industrial plants including utility affiliation involving the sale of central station service to industrial plants and supervising the activities of industrial pwr. salesman. Desires permanent connection preferably as representative of mfr. in an industrial center. C-5546.

E.E. GRAD., 1931, southern univ., married, 21, experience: sales engr., radio service, public address systems, production work location, and estimates. College major hydroelectric systems and transmission. Desires position in above field, especially sound engr. or location work. U.S. or foreign location. D-983.

PWR. SALES ENGR., E.E. grad., 1928, 25, married. One yr. Westinghouse Test Course, 3 yr. with large engg. corporation; pwr. plant and substation design and layout, contact man with elec. mfrs., extensive industrial engg. Desires permanent position as pwr. sales engr. or other engg. work. Excellent references, location, immaterial. C-4303.

E.E., 27, single, 28 graduate. Fifteen months G.E. Test. Two yr. sales experience with elec. servicing concern. Desires position with utility or mfg. concern. Has following with all eastern utilities. Eastern location advantageous. D-974.

ENGR., E.E.-Mech. grad. Yale Univ., 39, married. Eighteen yr. experience on machine tools, G.E. Test and engg. application, sales and sales promotion of elec. equipment. Qualified engr. for research and marketing, also application engr. for elec. and mech. equipment. Available immediately. Location preferred, New York Territory. D-1074.

SALES ENGR., 30, single, E.E. grad. of a reputable 1 yr. engr. school. Five yr. experience selling industrial and central station instruments. Desires position as salesman with a high grade mfg. concern. No particular line desired. Will travel, location, immaterial. C-1570.

# Membership

## Recommended for Transfer

The board of examiners, at its meeting of June 15, 1932, recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed with the acting national secretary at once.

### To Grade of Fellow

Gay, Frazer W., asst. engr., United Engineers & Constructors, Inc., Newark, N. J.

### To Grade of Member

Allen, R. W., distribution engr., Narragansett Elec. Co., Providence, R. I.
Carrick, John F. C., sales agent, Genl. Elec. Co., Niagara Falls, N. Y.
Chetham-Strode, A., station design engr., Dallas Pwr. & Lt. Co., Texas.
Coover, Mervin S., prof. of elec. engg., Univ. of Colo., Boulder.
Hamburger, Ferdinand, Jr., instructor, Johns Hopkins Univ., Baltimore, Md.
Harrison, S. H., supt., Vulcanite Portland Cement Co., Phillipsburg, N. J.
Ketchum, Wm. D., engr., Commonwealth & Southern Corp. of N. Y., Birmingham, Ala.
Konn, Felix, design section, motor division, Genl. Elec. Co., Erie, Pa.
Lambert, Alexander B., elec. engr., Crompton Parkinson, Ltd., Toronto, Ont., Can.
Laurtizen, Carl W., asst. prof. of elec. engg., Valparaiso Univ., Ind.
McFarland, T. C., assoc. prof. of elec. engg., Univ. of Calif., Berkeley.
Morecock, Earl M., coordinator of elec. students Rochester Athenaeum & Mechanics Institute, N. Y.
Penniman, A. L., Supt. of steam stations, Consolidated Gas, Elec. Lt. & Pwr. Co., Baltimore, Md.
Price, John R., prof. of elec. engg., Univ. of Wisconsin, Madison.
Rice, Harold F., asst. prof. of elec. engg., Univ. of No. Dakota, Grand Forks.
Robertson, Burtis L., asst. prof. of elec. engg., Univ. of Calif., Berkeley.
Skolfield, Wm. K., designing engr., Genl. Elec. Co., Bridgeport, Conn.
Stover, James R., elec. engr., W. S. Barstow & Co., Inc., Reading, Pa.
Wilson, Henry E., relay engr., Carolina Pwr. & Lt. Co., Raleigh, N. C.

## Applications for Election

Applications have been received at headquarters from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the acting national secretary before July 31, 1932.

Boland, W. I., 801 Sutter St., San Francisco, Calif.
Bottimer, G. W., Consumers Pwr. Co., Grand Rapids, Mich.
Bowman, J. H., Purdue Univ., Lafayette, Ind.
Burckmyer, L. A., Jr., Cornell Univ., Ithaca, N. Y.
Cohn, D. E., R. R. Commission of South Carolina, Columbia.
Cook, I. M., Shell Oil Co., Los Angeles, Calif.
Crum, E. R., Crum Elec. Co., Memphis, Tenn.
Davenport, L. B., Houston Armature Wks., Texas.
Dockendorf, J. P., Airways Radio Sta.. U.S. Dept. of Commerce, Sweetwater, Texas.
Geyer, P. W., Lackawanna & Western R. R. Co., Hoboken, N. J.
Hucks, George J., Pacific Tel. & Tel. Co., San Francisco, Calif.
Kajiura, K., Japanese Gov. Ry., N. Y. City.
Lambert, J. L., Tooke Bros., Montreal, Que., Can.
Maier, J., 1830 2nd Ave., N. Y. City.
Manucia, J. H., Manhattan Elec. & Radio Corp., N. Y. City
Meinders, J. J., New York Edison Co., N. Y. City.
Neubacher, L. L., Pacific Gas & Elec. Co., San Francisco, Calif.
Noble, D. E., Conn. Agri. Col., Storrs.
Nye, E. C., (Member), Instrument Serv. Labs., St. Louis, Mo.
Powell, C. A., 816 Blvd., Westfield, N. J.
Sholl, R. R. (Member), N. Y. & Queens Elec. Lt. & Pwr. Co., Flushing, N. Y.
Skvorzoff, M., 200 W. 111th St., N. Y. City.
Trueblood, R. O., Univ. of Wyoming, Laramie.
23 Domestic

### Foreign

Ali, S. N., H. H. Gov., Patiala State, Punjab, India
Beljavsky, A. G. (Member). North-Caucas Inst. of Energetics, Novocherkassk, U.S.S.R.
Bryant, A., Kenya & Uganda Governments, Nairobi, Kenya Colony, E. Africa.
Chan, S., 33 Wan Tsai Rd., Hong Kong, China.
Crisp, H. K., Municipalities of Bowral and Mittagong and Shire of Nattai Bowral, New South Wales, Australia.
Gokli, K. N., R. Gokli & Co., Matunga, Bombay, India.
Gomez, A., Chilean State Rys., Valparaiso, Chile, So. Am.
Headland, H., Public Wks. Dept., Waitaki Hydro, South Island, N. Z.
Hickey, M. G., Hackbridge Elec. Construction Co., Hersham, Walton-on-Thames, Surrey, Eng.
Perry, A. M., Hachbridge Elec. Construction Co., Surrey, Eng.
Sawhney, B., Assoc. Electrical Industries, Lahore, India.
Thampan, K. C., Pykara Construction Wks., Glen Morgan P. O., The Nilgiris, So. India
Verma, R. P., Gaya Engineering & Elec. Pwr Supply Co., Ltd., Gaya, India.
13 Foreign

# Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the address as it now appears on the Institute records. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Archbold, Earl J., Box 2641, Birmingham, Ala.
Blugerman, L. N., 227 N. 18th St., Phila., Pa.
Bugg, Vernon, 736 Transp. Bldg., Washington, D. C.
Callen, R. J., Brunswick Recording Lab., 799 7th Ave., N. Y. City.
Iwe, Halfdan G., 229 Ovington Ave., Bklyn., N. Y.
Palit, Hari-Charan, 151 Ganesh Mohal, Benare City, India.
Pearson, Ernest, 209 Brewster Rd., Scarsdale, N. Y.
Rogge, C. A., Consumers Pwr. Bldg., Jackson. Mich.
Scanlon, D. L., KFPW, Ft. Smith, Ark.
Schwartz, Carl, 410 Cathedral Pkwy., N. Y. City.
Thomas, Earl Mead, Intl. Genl. Elec. Co., Schenectady, N. Y.
Titland, Trygve T., 1019 Stanton Ave., Elizabeth, N. J.
Van Ness, L. G., 2105–6 Sterick Bldg., Memphis, Tenn.
Vetri, L., Western Elec. Co., Inc., 100 Central Ave., Kearny, N. J.

# Engineering Literature

## New Books
### in the Societies Library

Among the new books received at the Engineering Societies Library, New York, during May are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no reponsibility for statements made in the following outlines, information for which is taken from the preface or text of the book in question.

GALVANISCHE ELEMENTE UND AKKUMULATOREN. By C. Drucker and A. Finkelstein. Leipzig, Akademische Verlagagesellschaft, 1932. 425 p., illus., 10x7 in., cloth, 36 rm.—Intended for the manufacturer of dry cells and storage batteries who wishes an account of the fundamental theory as a basis for research work, and is also interested in a discussion of methods of manufacture. Raw materials, methods of construction, uses, and properties of dry cells and accumulators, are described in a practical way. One-third of the book is an extensive index to German, British, and American patents since 1910.

GASOLINE AUTOMOBILE. By B. G. Elliott and E. L. Consoliver, 4 ed. N. Y. and Lond., McGraw-Hill Book Co., 1932. 605 p., illus., 9x6 in., cloth, $3.00.—The fundamentals of automobile construction, maintenance, and operation are set forth in this work with sufficient fulness for the needs of the owner, operator, repair man, and student. The text is clear and explicit and amply illustrated with photographs and drawings. The revision has been thorough and complete.

HANDBOOK OF THE COLLECTIONS ILLUSTRATING LAND TRANSPORT. III, Railway Locomotives and Rolling Stock. Part 1. Historical Review. By E. A. Forward. London. South Kensington Science Museum, 1931. 99 p., illus., 10x6 in., paper, 2s6d.—This pamphlet provides a very useful, concise review of the development of the locomotive and the railroad car in the British Isles. The locomotive occupies most of the space, and its evolution is expertly traced from Trevithick's experiments in 1801 to the latest types. Electric and internal combustion engines are included.

KOLLOIDCHEMISCHE TECHNOLOGIE. By R. E. Liesegang, 2nd ed. Dresden and Leipzig, Theodor Steinkopff, 1932. 1085 p., illus., 11x7 in., paper, 68 rm., cloth, 72 rm.—An extensive review of practical applications of colloid chemistry, in the form of essays by a number of specialists. The subjects considered include among others lubricants, textiles, rayon, paper, plastics, electrical insulating materials, Portland cement, water, sewage, petroleum emulsions, metallurgy, and flotation. The articles are concise and up to date and contain numerous references to sources. A useful survey of its subject.

HIGH-SPEED DIESEL ENGINES. By P. M. Heldt. Phila., P. M. Heldt, 1932. 312 p., 9x6 in., cloth, $4.00.—Although there is a number of books on Diesel engines, this is the first American treatise specifically for the high-speed oil engine for automotive use. It aims to give an orderly condensed review of the research work done in America and Europe on problems connected with design, with descriptive data and illustrations of typical examples of the various sub-classes. The book brings together an amount of material of interest to designers and experimenters, especially for automobile and aircraft engines, which heretofore has been widely scattered.

NORMALISATIONS, SPÈCIFICATIONS ET PRESCRIPTIONS TECHNIQUES, 1930–31. Union des Syndicats de l'Électricité, Paris, 1931. 1024 p., 9x6 in., cloth, 50 fr.—A collection of rules and standards governing the construction, erection, and operation of electrical equipment as in force in France. Includes standards of the International Electrotechnical Commission, the French Electrotechnical Commission, the Union des Syndicats de l'Électricité, and other associations of engineers and manufacturers, and of government agencies. Convenient and comprehensive.

PRINCIPLES OF PUBLIC UTILITIES. By E. Jones and T. C. Bigham. N. Y., Macmillan Co., 1931. 799 p., 9x6 in., cloth, $4.25.—A text on the economics of public utilities, a text-book for students and a manual for officials, engineers, and others interested in public utility problems. The discussion is confined to the utilities supplying electric light and power, gas, street railway service, telephone service, and water. The subjects treated include regulation, valuation, rates, finances, combinations, public ownership, and other outstanding problems.

TABLES ANNUELLES DE CONSTANTES ET DONNEÉS NUMÉRIQUES DE CHIMIE, de Physique, de Biologie et de Technologie, 1929, v. 9. Paris, Gauthier-Villars et Cie; N. Y., McGraw-Hill Book Co., 1931. 1607 p., 11x9 in., cloth, $12.00.—With this issue this important reference work is again upon an annual basis. The present volume contains all the constants and numerical data published during 1929 in the fields of chemistry, physics, biology, and engineering. The series is an indispensable supplement to the "International Critical Tables" and is essential to every research worker. Text in both English and French.

TRANSFORMATEURS DE MESURE ET RELAIS DE PROTECTION. By C. Bresson. Paris, Dunod, 1932. 293 p., illus., 10x6 in., cloth, 91 fr.—Two important questions in distribution systems are discussed. The first half discusses the characteristics of instrument transformers, the qualities that effect their efficiency, and their use in distribution systems. The remainder of the book describes the principal types of circuit breakers and protective relays and illustrates their uses.

ÜBER DEN SCHALLSCHUTZ DURCH BAUKONSTRUKTIONSTEILE. (Beihefte zum Gesundheits-Ingenieur, Reihe 2, Heft 11.) By H. Reiher. München and Berlin, R. Oldenbourg, 1932. 28 p., 12x9 in., paper, 4.80 rm.—By tests in laboratory and buildings the soundproofing properties of over 200 old and new structural elements were determined accurately. The results are presented in tables, accompanied by an account of the theory of sound propagation and of transmission, and a description of the methods of measurement used in this investigation. General conclusions are drawn from the tests and minimum requirements suggested.

AIRCRAFT YEAR BOOK, v. 14, 1932. By Aeronautical Chamber of Commerce. N. Y., D. Van Nostrand Co., 1932. 626 p., illus., 9x6 in., cloth, $6.00.—Part I records outstanding events of the year's aviation, American and elsewhere; part II deals with engineering and manufacturing progress and illustrates American aircraft and engines; part III is a chronology of important contests and records. The remainder gives useful statistics and directory of officials, associations, etc. A convenient summary of all matters of aviation.

AM. SOC. FOR TESTING MATLS. INDEX TO PROCEEDINGS, v. 26–30, 1926–30. Phila., A.S.T.M., 1932. 251 p., 9x6 in., to members, cloth, $1.75; half leather $2.75; non-members (cloth $2.50, half leather, $3.50.—A full subject and authors' index to these proceedings of the society, for testing materials and the study of their properties. A supplement to the first 25 vols.

BARRAGES CONJUGUÉS ET INSTALLATIONS DE POMPAGE. By G. Laporte. Paris, Gauthier-Villars et Cie, 1932. 144 p., 10x7 in., paper, 35 frs.—An investigation of economic possibilities of increasing hydroelectric output by pumping water back to reservoirs with off-peak power; especially suitable where 2 or more plants upon 1 river are operated together. Feasible plans of pumping are discussed, and plant characteristics suited to each determined.

BIBLIOGRAPHY OF AERONAUTICS, 1930. Natl. Advisory Comm. for Aeronautics. Washington, D. C., U. S. Govt. Prtg. Office, 1932. 261 p., 10x7 in., paper, $0.50.—1930 literature including references to articles in principal world magazines. Alphabetized with authors and subjects in one listing. A continuation of a series which covers the subject from early times.

COLLOID CHEMISTRY, v. 4. Ed. by J. Alexander. N. Y., Chem. Catalog Co., 1932. 734 p., illus., 9x6 in., cloth, $11.50.—Concludes a series of valuable papers published by Dr. Alexander during past 6 years. Devoted to technological applications and items on colloid chemistry of cellulose, paper, explosives, sugar, and other carbohydrates; dyeing; rubber; plastics; tanning; paints; electroplates, etc.; solidified alcohol; fire extinguishers; water supply and sewage disposal.

DIELECTRIC. III. BREAKDOWN OF SOLID DIELECTRICS. By S. Whitehead, ed. by E. B. Wedmore. London, Ernest Benn, 1932. 346 p., illus., 9x6 in., leather, 30s.—This completes the survey of dielectric phenomena prepared by the British Elec. and Allied Industries Research Board. Is a critical summary of information available on dielectric phenomena with particular reference to the theoretical basis and failure of insulation in service. Includes bibliography.

EARTH DAM PROJECTS. By J. D. Justin. N. Y., John Wiley & Sons, 1932. 345 p., illus., 9x6 in., cloth, $5.00.—An endeavor to set forth the principles of design and construction useful to the engineer, illustrating applications by concrete examples. It opens with description of dam failures and the causes, treating of preliminary investigations and surveys, subsurface investigations, and materials and laboratory tests. Problems of design and construction are given in detail and various methods of building described. Ends with description of a number of representative dams. As the only such work in print, it fills a distinct need.

EINFÜHRUNG IN DIE THEORETISCHE ELEKTROTECHNIK. By K. Küpfmüller. Berlin, J. Springer, 1932. 285 p., illus., 10x7 in., cloth, 19.50 rm.—An introduction to elec. engg. theory intended to fill a field between elementary text and treatises upon specific applications. Confined to facts and methods required as a general background by the engineer interested in development of electricity. Holding to essential physical laws makes thoroughness possible in a book of moderate size.

ELEKTROTECHNISCHE GESELLSCHAFT, Frankfurt am Main, 1881–1931. Geschichtstafeln der Electrotechnik. Collected by S. Ruppel. Berlin-Charlottenburg, Verband Deuts. Elektrotechniker, 1932. 127 p., illus., 12x8 in., paper, 6 rm.—A memorial volume for the 50th anniversary of the Elect. Engg. Soc. of Frankfurt. A series of interesting tables of outstanding dates and developments on theoretical principles, generators, motors, machine tools, railroads, transmission lines, insulators, cables, switch-gear, power plants, lighting, storage batteries, meters, telephony, radio, etc. Statistics also are given showing the growth of industry.

ELEMENTS OF ELECTRICAL DESIGN. By A. Still. 2 ed., N. Y. and Lond., McGraw-Hill Book Co., 1932. 583 p., illus., 9x6 in., cloth, $5.00.—Presenting the elements of electrical design. Not to train designers, but to give students an understanding of fundamental principles in application to concrete designs. A new edition revised thoroughly for the trend toward higher operating voltages and improved efficiency.

FARADAY AND MAXWELL. (Deutsches Museum Abhandlungen und Berichte, Jahrg. 4, Heft 1.) By E. Cohn. Berlin, V.D.I.-Verlag, 1932, 29 p., illus., 8x6 in., paper, 90 rm.—An essay linking the lives and work of Maxwell and Faraday in a most interesting way, and showing how our present principle of energy through Maxwell's studies was evolved from Faraday's experiments.

GESCHLICHTLICHE EINZELDARSTELLUNGEN AUS DER ELEKTROTECHNIK, v. 3. By Elektrotech. Verein. Berlin, J. Springer, 1932, 125 p., illus., 9x6 in., cloth, $2.64.—Three interesting papers in a new volume of a series. Dr. Weicker gives a history of the development of insulators for overhead lines; Dr. Fischinger the early history of the Lauchhammer power plant, the first 100-kv. plant in Europe; and Dr. Poschenrieder gives interesting recollections of his experiences in the infancy of elec. engg.

ILLUSTRIERTE TECHNISCHE WÖRTERBÜCHER, Deutsch, Englisch, Französisch, Italienisch, v. 17. AERONAUTICS. Ed. by A. Schlomann. Berlin, V.D.I.-Verlag, 1932. 740 p., 10x7 in., cloth, 30 rm.—This volume follows the general plan of the series to which it belongs, with about 13,000 terms being arranged systematically; indexes in German, French, Italian, and English. Illustrated freely. Prepared with the assistance of a number of engg. soc. and firms, aviation boards, and govt. bureaus. Claimed superior to any dictionary available and welcome to translators.

### Engineering Societies Library

29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a cooperative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

# Industrial Notes

**Electric Heat Speeds Plant Growth.**—Electric heat furnished by General Electric soil-heating equipment during the 1931–1932 season helped improve the quality of farm products, aided in getting them to market earlier, helped growers to a profit, and gave power companies an additional annual consumption of one and a half million kilowatt-hours of electric current, declared G. A. Rietz, in charge of the rural electrification section of the company, in a recent talk before rural electrification specialists of the Niagara-Hudson Power Company. The equipment, including cable and thermostats, was sold to farmers throughout the United States on an active commercial basis for the first time last season. The bulk of the power is used between sundown and sunrise, making it practically an offpeak load.

On the strength of sales activity in cooperation with central station representatives, and the testimony of thoroughly beneficial results, the demand for electric hot-bed equipment is expected to more than treble the kilowatt-hour load for the next growing season. "This estimate is based on the enthusiastic acceptance and adoption this past season, the present demands for the coming season, and the reports made on results by commercial growers. All these indications point to an additional 5,000,000 kilowatt-hours in annual consumption during the coming season by reason of new installations of this heating equipment," Mr. Rietz said.

**A New Insulation.**—A new chemical product which has practically all of the characteristics of rubber, but which is not affected by solvents, has been in commerical production for some time past. It is an olefin polysulfide reaction product known as Thiokol, and is manufactured by The Thiokol Corporation, Yardville, N. J. This product is made entirely of chemicals through a simple process and like rubber it is compounded and vulcanized in the processing of finished articles. Unlike rubber, Thiokol compounds do not age or perish in storage. Oxygen does not appear to affect it and the ozone generated during electrical corona tests does not cause deterioration. A number of leading electrical manufacturers are said to be testing Thiokol at present for use in the following applications: protective covering for underground low voltage cable; connections for oil filled cables in place of cement; submarine cables; ignition cables to protect against oils and corona conditions; transformer gaskets, high voltage cable covering in place of lead, and others.

**New Tachometer.**—A new direct-reading hand tachometer for testing r.p.m. machine speeds has been developed by the Amthor Testing Instrument Co., Inc., 309 Johnson St., Brooklyn, N. Y. It incorporates the new feature of automatic fixed reading whereby speed readings are automatically fixed on the dial after use. The dial reads directly in r.p.m., but all accessories are included so that "feet per minute" surface belt speeds can be taken. Various ranges can be had to directly measure speeds as high as 12,000 r.p.m.

**U. S. Magnetic Products Corp. Elects M. B. Mervis.**—According to a recent announcement, M. B. Mervis, formerly secretary-treasurer and general manager of the American Insulated Wire & Cable Company, has been elected chairman of the board of the U. S. Magnetic Products Corp., Chicago and Lock Haven, Pa. Manufacturing facilities are being augmented by the addition of more modern machinery for coil winding and for manufacturing electromagnets, solenoids, various types of small transformers, and magnetic specialties.

# Trade Literature

**Lightning Arresters.**—Bulletin GEA-93H, 16 pp. Describes G-E lightning arresters for pole mounting, pellet type and compression-chamber types. General Electric Co., Schenectady, N. Y.

**Lugs.**—Bulletin, 10 pp. Describes a complete line of copper soldering lugs. Ilsco Copper Tube & Products, Inc., 5629 Madison Road, Cincinnati, Ohio.

**Graphic Meters.**—Bulletin 632, 10 pp. Describes newly designed models of a complete line of graphic meters, made in switchboard, wall, portable and other types. The Esterline-Angus Co., Indianapolis, Ind.

**Transformers.** Bulletin 172, 54 pp., looseleaf. Describes all types of Wagner distribution transformers. Construction features are profusely illustrated and described in detail. Wagner Electric Corp., 6400 Plymouth Ave., St. Louis, Mo.

**Induction Motors.**—Bulletin 111, 8 pp. Describes type AA Reliance squirrel-cage induction motors for two- and three-phase alternating current circuits, 40°C. continuous duty, open rating. Reliance Electric & Engineering Co., Ivanhoe Rd., Cleveland, Ohio.

**Potentiometers.**—Bulletin, 8 pp. Describes potentiometers for research, standardizing and educational laboratories. Kelvin and Wheatstone bridges and resistance boxes are part of the line. Gray Instrument Co., 64–70 W. Johnson St., Germantown, Philadelphia, Pa.

**Dry Metallic Rectifiers.**—Bulletin. Describes a new unit of the type "F" rectifiers, providing a reliable source of small amounts of d-c. power for the operation of sensitive electrical equipment such as relays, electromagnetic counters, industrial control devices, etc. B-L Electric Mfg. Co., 19th & Washington Ave., St. Louis, Mo.

**Dust Filters.**—Bulletin, 28 pp. Describes the application of air filters now installed in many industries. A chapter is included illustrating the use of such filters in connection with the air cooling of various types of electrical equipment such as turbogenerators, synchronizing condensers, frequency changers, substations, etc. American Air Filter Co., Inc., Louisville, Ky.

**Cedar Pole Specifications.**—Bulletin (Supplement No. 2), 24 pp. Contains the new American Standards Association specifications for both Northern White and Western Red cedar poles with other relevant information and data. Preparation of poles for butt treatment through the use of new perforating machines is described. The MacGillis & Gibbs Company, Milwaukee, Wis.

**Nofuze "De-ion" Circuit Breakers.**—Catalog 2246, 76 pp. Describes Nofuze load centers, panelboards, switchboards, meter services, outdoor and indoor commercial and industrial type circuit breakers, all using the "De-ion" principle of arc extinction, which enables the elimination of fuses and knife switches for circuit protection and control. Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

**Fuse Links.**—Bulletin 511, 8 pp. Describes the following types of Matthews fuse links, -bimetallic universal; fast blowing universal; open type bimetallic universal and spring type. Ampere ratings, catalog numbers, time current curves, fusing schedules indicating correct size link to use and proper method of application are discussed. W. N. Matthews Corp., 3700 Forest Park Blvd., St. Louis, Mo.

**Magnetic Clutches.**—Bulletin, 16 pp. Describes three types of Dings magnetic clutches—single disk, multiple disk, and serrated disk applications for special and general power transmission. A number of installation diagrams are reproduced and the method of calculating the required horsepower rating is discussed in detail. Extensive tables of performance data are also included. Dings Magnetic Separator Co., Milwaukee, Wis.

**Coupling Condensers.**—Bulletin 601-H, 24 pp. Describes a new development consisting of coupling condensers as a means of securing low voltage from high voltage circuits for operating instruments such as voltmeters, synchronoscopes and relays. Included is a detailed discussion of the electrical characteristics of circuits for various set-ups, with curves and wiring diagrams. Economies which are achieved are also presented. Ohio Brass Company, Mansfield, Ohio.

**Motors.**—Bulletin 210, 20 pp. Describes the Noel polyphase capacitor motor, which employs capacitors in a patented connection to obtain internally a power factor of unity (100%), or 80% leading, in squirrel cage and slip-ring induction motors. In addition to possessing all the advantages of the ordinary motor it is claimed that the Noel motor has a greater starting torque, a lower starting current, better efficiency, and higher speed at all loads. The Ideal Electric & Mfg. Co., Mansfield, Ohio.

THE PROXIMITY effect may be utilized to control the path of electric current used for heating where it is desired that the heating be confined to predetermined strips of the conducting bodies. *p. 559–562*

PRIVATE-WIRE teletypewriter service provides the speed, accuracy, and wide coverage necessary in the communication facilities of the modern police system. Several statewide networks now are in use. *p. 550–553*

A VOLTAGE LIMITING gap for protecting power station apparatus has been developed, the breakdown characteristics of which can be varied over a wide range so as to conform to the characteristics of the station insulation. *p. 579–582*

FIELD observations of conductor vibration on electric power transmission lines substantiate the results of laboratory investigations. Results show that adequate practical protection can be provided by armor rods or dampers. *p. 562–568*

A 3,000-KW sectionalized mercury arc rectifier has been found by tests to have an efficiency one per cent higher than that of the conventional single unit type. *p. 576–579*

MAN'S RETREAT from light into darkness and from ventilated atmosphere to stagnant air is exacting its penalty. So says a medical authority in the twelfth article in the Engineering Foundation's Symposium, "Has Man Benefited by Engineering Progress?" *p. 553–555*

ULTRA precise practical timekeepers of today are of one of 2 classes, depending upon whether the restoring force is gravity as in pendulum clocks, or elasticity as in quartz crystal oscillators. The latter type is a development of recent years and has progressed so that the constancy of rate is comparable with that of the best pendulum clock. *p. 542–549*

ECONOMIC factors are important these days, especially where they concern one's own pocketbook. Members planning to attend the A.I.E.E. Pacific Coast convention August 30 to September 2, 1932, in Vancouver, B. C., may be attracted by the reduced entertainment fees and the exchange rate between Canadian and U.S. currency that at present favors U.S. currency if the exchange be made at a bank. *p. 588.* Abstracts of technical papers scheduled for presentation are published in this issue. *p. 583–586*

COLORFUL pictures of Baltimore, Md., and its attractions for those attending the A.I.E.E. Middle Eastern District meeting, to be held in that city October 10–13, 1932, are presented in a preview written by a member of the local convention committee. *p. 587*

IMPORTANT discussions of papers presented during the Institute's recent summer convention at Cleveland, Ohio, June 20–24, 1932, have been summarized. *p. 590–595*

EDUCATION has been the subject of a number of recent papers presented before the Institute. One of these papers analyzes the various electrical and related subjects in the program for electrical engineering in a number of technical institutions. *p. 568–571*

INTEREST in the "Letters to the Editor" columns of ELECTRICAL ENGINEERING is growing rapidly. These contributions take many forms. Responses which have been received indicate that these letters are widely read. *p. 597–599*

A TENTATIVE standard for engineering abbreviations has been adopted by the sectional committee on scientific and engineering symbols and abbreviations of the American Standards Association. This tentative standard is strictly an editorial specification. The terms most commonly used in electrical engineering literature are presented in this issue. *p. 589–590*

# To Members of the Institute—

IN ASSUMING the duties as your president, I welcome the opportunity afforded through Electrical Engineering to express my deep appreciation of the honor you have conferred upon me and to say a few words concerning the activities of the Institute for the coming year.

We are passing through a most difficult period and if we were to approach the year ahead with the least hesitancy or lack of confidence, we most certainly would not make the progress which has been so characteristic of the Institute in past years. However, we do not lack confidence as to the future; we recognize that we have but paused in a forward movement toward even greater technical and professional achievements. If we recognize this period, therefore, as a golden opportunity to consolidate our forces and build an even better organization for the future opportunities so definitely ahead of us, I am sure that we will not only carry on with still greater benefit to each other and to society as a whole, but also we will establish an even higher esteem in the mind of the public as to the importance and value of our profession.

We have but to look back a relatively few years to realize the remarkable advances that have been made in a short span of time in all phases of the arts and sciences with which we are concerned. Not a day passes without new vistas opening before us and revealing the way to new opportunities which cannot but lead to further material improvements and social advancements. Occasionally we hear the question raised as to whether scientific research and the general extension of engineering knowledge are not proceeding too rapidly for the common good, and consequently by some process might better perhaps be retarded. Aside from the impracticability of such considerations—touching as they do on man's curiosity about the unknown, or the stopping of the flow of new things which man believes to be valuable additions to social life—those who have given these matters serious study realize that the problem centers not in the products of science, but rather in the fact that our knowledge as to the proper use of the results of our scientific advancements has not developed nearly as rapidly as have the products of our research and engineering activities. These are matters which we of the Institute who are concerned in one way or another with the fundamental or applied sciences must consider. Our opportunity lies before us in the chance to help to bring about the effective general understanding of these matters that seems so necessary.

Not only in those things of which I have spoken, but likewise in the general solution of the problems which confront the world at large at the present time, there is urgent need for the help of individuals trained to discover facts and able to turn our efforts in the directions which such facts indicate. By basic training and practical experience, the engineer is indeed qualified to assist in just such a challenging task, and I am confident that we shall find him taking an ever greater and greater part, in full cooperation with others, in finding the solution of the serious problems confronting our nation and the world in general.

It seems to me, therefore, that we are in an era when the problems of the engineering profession are undergoing some rather important changes in their fundamental aspects, but in spite of our present temporary difficulties, I believe that these very changes, as well as other factors, all point to further progress and opportunity for those of our profession.

Within the Institute itself, this next year naturally will present many difficult problems and we should be prepared to shape its policies and procedures to conform to the times and conditions as encountered. Financial matters will require most careful consideration to the end that, while maintaining the financial integrity of the organization, we may as far as practicable continue the essential services to our members. I bespeak your hearty support of the headquarters and committee personnel faced with this and other important problems incident to these trying times, including the difficult questions involved in the Institute's publication services.

To our committees and the activities of our Sections we look, as in the past, for the spreading of interest and the enhancement of the value of our society to our members. At no time in Institute history have the activities of these groups been more important than at present, when it is hoped that we may not only hold together our great organization to as nearly as possible its full membership, but also add to its strength and solidarity.

Always of the greatest value, but now of more than usual importance, I believe, are the activities of our Student Branches. The problems confronting our younger members are more than usually difficult at this time, and it is hoped that the cooperation between our Sections and Branches may be fostered to an even greater and more effective degree than in the past. Such contacts must inevitably result in mutual encouragement, and benefit not only our student members but also our older members.

As for myself, my service in the Institute long has been one of my greatest pleasures, and I welcome with keen anticipation the new opportunities which will be afforded me as your president to break down the barriers that distance creates for us, visiting again the various Sections, and through professional as well as personal contact have the privilege of carrying on with you the important activities which we shall find in hand during the coming year.

**PRESIDENT**

# Modern Developments in Precision Timekeepers

Clocks of the gravity or pendulum type have for many years been used as precision timekeepers; but through recent refinements they have been made more accurate and reliable. Another development of the last decade is the use of the elasticity of quartz crystal oscillators as the restoring force in precision timekeepers; this has been made possible by the vacuum tube and associated electrical circuits. Both types of timekeepers are discussed in this article.

AT THE BEGINNING of the present century it was believed by many that the limit of accuracy attainable by mechanical clocks had been reached. This presumption was based on the performance of specific mechanisms which had indeed been brought to a high state of perfection, but this presumption did not allow for the possibility of other types of mechanism for measuring time or for certain refinements which since then have more than doubled the accuracy and reliability of the best clocks then available.

As the words clock, chronometer, etc., have come to have definite technical meanings in the art, the more general term "timekeeper," will be used. In the broadest sense a timekeeper may be defined as any physical means that can be used for the subdivision of time into intervals known in terms of a standard time interval. Thus, any periodic phenomenon can be adopted in a timekeeper provided its period can be recorded in terms of another. In this sense the earth and the moon are timekeepers, as are vibrating pendulums, tuning forks, and other sustained oscillators.

As all man-made timekeepers are essentially "oscillators" consideration will first be given the equation of motion of a simple oscillator which can be expressed as $M\ddot{x} + R\dot{x} + Sx = A \sin(\omega t + \phi)$ where $M$ corresponds to the mass, $R$ to the resistance or damping and $S$ to restoring force proportional to displacement $x$. The right hand term represents the sustaining force required on account of the dissipation of energy in the oscillator. For an oscillator to be a perfect timekeeper, all of the quantities, $M$, $R$, $S$, $A$, and $\phi$, must remain invariable. While $M$ and $S$ are the chief rate governing quantities, the others from a design point of view are the most difficult to control.

The ultra precise practical timekeepers of today may all be contained within 2 classes, depending upon where $S$ (the restoring force) is

1. Gravity (as in pendulum clocks)
2. Elasticity (as in quartz crystal oscillators)

The second class is a development of the last decade and was made possible by the development of the vacuum tube and associated electrical circuits. Intercomparisons between timekeepers of the 2 classes provide a most valuable means for the study of changes in gravity and related phenomena. These 2 classes are discussed separately.

## GRAVITY TIMEKEEPERS

Unfortunately the motion of a pendulum is not quite simple harmonic motion since the restoring force varies as the sine of the angular displacement (instead of directly as the displacement) and therefore the period is not truly independent of the amplitude. This can be seen from the equation of motion of the pendulum which in its simplest form, neglecting damping and sustaining forces, is

$$Ml\ddot{\theta} + Mg \sin \theta = 0$$

The free period $T$ for any given angular displacement can be expressed by the series:

$$T = 2\pi\sqrt{\frac{l}{g}}\,(1 + 0.0625\,\alpha^2 + 0.00358\,\alpha^4 + \ldots)$$

where $\alpha$ is the maximum deflection from midswing expressed in radians. The corresponding change in rate expressed in seconds per day is shown in the curve, Fig. 1. Various attempts have been made to construct pendulums having a period independent of arc, but mechanisms to accomplish this result always have introduced larger irregularities than those which they attempted to cure. Practical design has been confined to keeping the amplitude small and to providing a governing action so that any slight increase in amplitude causes an opposing tendency to decrease the amplitude, or *vice versa*.

The old anchor recoil escapement accomplished this by increasing the friction on the pendulum with

---

Essentially full text of "Modern Developments in Precision Clocks" (No. 32-52) presented at the A.I.E.E. winter convention, New York, N. Y., January 25-29, 1932.

increase of amplitude. The inertia escapement in the Shortt clock attains a similar result without the serious disadvantage of introducing friction. This inertia escapement is based on the principle that a weight rolling down an inclined plane applies a greater horizontal force to a slowly moving plane than to a faster moving one. A suitable inclined plane attached to a pendulum receives an amount of energy roughly inversely proportional to the amplitude, or to the velocity at midswing. As the amplitude increases, the energy delivered into the system becomes less. But in spite of these controls the amplitude does vary in fact, which at the present time probably accounts for more irregularities than any other factor. Dr. J. Jackson has shown that if the daily amplitude is regularly recorded and the clock rate corrected accordingly, a number of the irregularities in the Shortt clocks at Greenwich can be explained.

If a direct amplitude control could be applied to a clock, such corrections should not be necessary. Such a method is now being tried on a Shortt clock in the Loomis Laboratory. When the amplitude of the pendulum exceeds a predetermined amount by even 0.0001 in., a signal is sent, via a pointed electrode which hangs in the evacuated pendulum casing, to a vacuum tube which operates a relay, so that the next 30-sec. driving impulse is omitted. The electrode is so adjusted that about every fifth impulse is omitted in this way. With this control the constancy of rate appears to be improved, but at least a year's record is needed for conclusive proof, as the variations which this device seeks to control usually only occur at intervals of several months.

The complete solution for the period of a pendulum swinging in a resisting medium, such as air, involves a factor $\sqrt{1 + kR^2}$ where $R$ is the resistance to motion and $k$ is a constant depending on the structure of the pendulum and the nature of the drive. Although it would appear from this that all pendulums should be operated in a high vacuum, practically it has been found that, from the standpoint of stability of period with pressure variation, the most satisfactory pressure for the Shortt clock is about 15 to 20 mm. of mercury. When the pressure is very low or at zero, the arc when not definitely controlled is very unstable and causes large changes in rate; but in the neighborhood of 15 mm. of pressure there is a stabilizing action due to the air friction, and a neutralization of the following four effects of pressure variation:

1. Change in the restoring force due to buoyancy of the pendulum in air.
2. Change of center of gravity due to buoyancy when the pendulum is made of dissimilar materials.
3. Change of effective mass due to air carried along by the pendulum.
4. Change of friction and consequent change in arc.

The first and fourth are probably of greatest importance. With decrease in pressure the first decreases the period and the fourth increases it. At the critical pressure the 2 effects are about equal and opposite. In the determination of gravity, where very precise pendulums are used, all of these factors must be considered carefully.

When the amplitude control device previously described is used, the pressure can be reduced to a small fraction of a millimeter, which thereby reduces the effect of friction to a minimum. The term $\sqrt{1 + kR^2}$ then becomes practically unity and the required sustaining energy can be very much reduced.

## VARIATIONS IN INERTIA

Because of its effect on inertia, the expansion of the pendulum with temperature must either be reduced or compensated for. At the present time practically all clocks of high precision employ invar pendulum rods with bobs of type metal or invar. The bob rests on an expansion collar, the dimensions of which are calculated to compensate for the lengthening of the rod. Some recent studies in Japan have produced a "super-invar," to use the expression given, which may have a zero or even a slightly negative coefficient of expansion. If these new alloys are as stable as invar, they may have an important use in precision clock making, as the entire pendulum could be made from a single piece of material.

With the new technique recently developed in the laboratories of the General Electric Company it is now possible to produce pieces of clear fused quartz large enough to construct the entire pendulum for a clock. Some experiments are now being conducted with such clocks in the Loomis Laboratory. Fused quartz has a temperature coefficient of expansion of about 0.5 part in $10^6$ per deg. cent. A temperature variation of one degree would therefore cause a change in rate of only 0.02 sec. per day due to this effect alone. In a constant temperature vault with a fused quartz pendulum a variation of 0.01 deg. would affect the rate only 0.0002 sec. per day; means have been developed whereby temperature can be controlled to within 0.01 deg. over long periods.

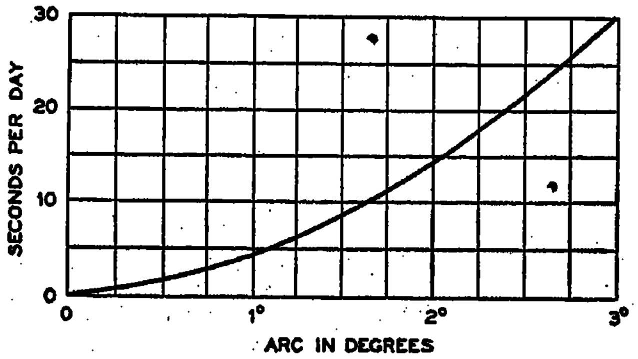

**Fig. 1. Change of rate of pendulum with semi-arc, expressed in seconds lost per day**

There are 2 other major effects which should be considered in connection with pendulum length. These are (1) variations in the position of the point of oscillation, and (2) the instability of materials with time, in other words, aging. The effect of knife edge wear on the period of an ordinary pendulum is appreciable. A wearing of 0.001 mm. will change the rate of a seconds pendulum nearly 0.1 sec. per day. Largely for this reason, a flexible spring suspension of elinvar[4] is used in most precision clocks. But even the spring is suspected of changes in length, and, what is just as bad, also of variation in stiffness which would change the point of flexure and the restoring force. Aging effects in the pendulum rod can be reduced only by finding better materials. It may be that fused quartz or possibly some large single crystal will be found finally to be the most suitable material to use.

The effect of knife edge wear on the period of a pendulum in theory can be avoided almost entirely by suspending the pendulum at a distance from its center of mass equal to the radius of gyration about that point. This simple principle of mechanics has of course long been recognized and experiments are being conducted in Germany[6] and elsewhere to determine its value in a precision timekeeper. In the case of a uniform straight rod this distance should be $\frac{1}{2\sqrt{3}}$ of the total length from the center. With this condition fulfilled a change in this length due to knife edge wear of one part in a thousand would affect the period less than one part in a million.

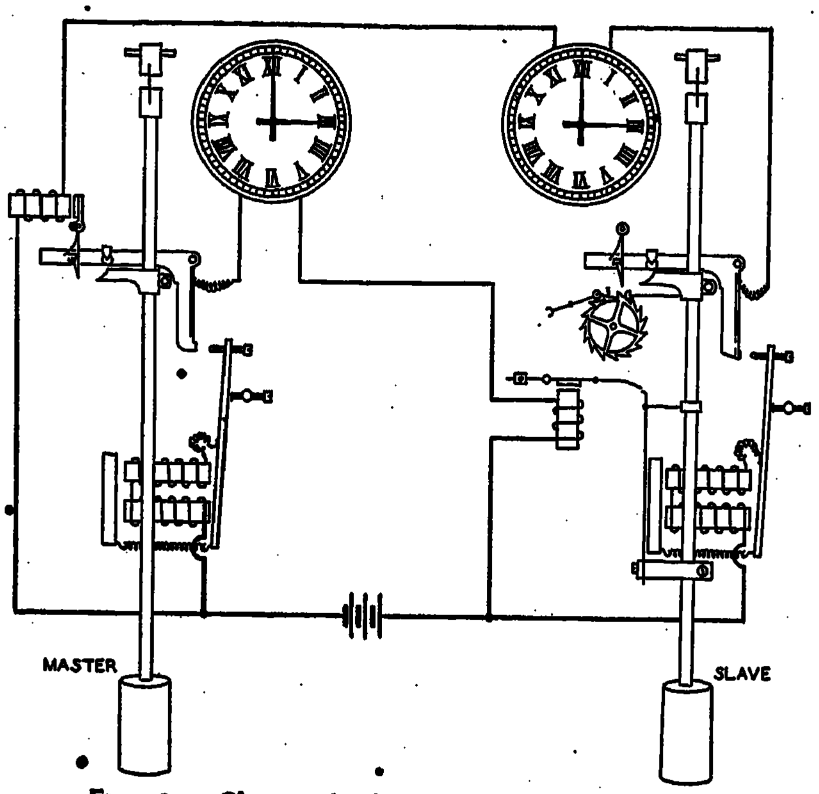

Fig. 2. Shortt clock mechanism and circuit

THE DRIVING FORCE

The terms on the left-hand side of the fundamental equation at the beginning of the article have been considered briefly. The right-hand term—the driving force—and especially the quantity $\phi$, the phase angle, which presents perhaps the most difficult problem in the design of all timekeepers, will now be considered.

The impulse should be delivered to the pendulum at the time when the velocity is at maximum; that is, at the center of the swing, in order to reduce to a minimum the effect of variations in the driving force upon the rate. If the impulse is applied before the instant of maximum velocity, the rate is increased momentarily. If the impulse is applied after the instant of maximum velocity the reverse is true. Of course the impulse actually is of finite duration and the desired effect is approximated by supplying the pulse symmetrically with respect to the instant of maximum velocity, thereby tending to neutralize the acceleration and retardation effects. The necessity for this method of applying sustaining power pulses to a pendulum has been realized almost from the beginning of precision clock history but cannot be overemphasized.

The 3 clocks most often recognized as precision timekeepers are the Leroy, Riefler, and Shortt. One or more of these is to be found in most of the important time laboratories and astronomical observatories throughout the world. In the Shortt clock the impulse to the master pendulum is controlled by means of an auxiliary or "slave" pendulum which in turn is automatically synchronized with the master pendulum to within ±0.003 sec. at all times. The means by which this is accomplished can be seen from Fig. 2 which shows the master and slave pendulums with all the essential control elements, and the counting or time indicating dials. Although the master pendulum determines the rate of the system, the slave pendulum and associated mechanism does the work of releasing the driving pulses at the proper time. The slave pendulum, through a jeweled ratchet and pawl-operated count wheel, releases mechanically a weight arm once each 30 sec. at just the right time so that a small wheel on the gravity lever, rolling down a curved inclined track associated with the slave pendulum rod, imparts the sustaining impulse to it. As soon as the mechanical impulse is delivered, this arm closes an electrical contact which resets the weight arm before the return swing of the pendulum, in readiness for the next 30-sec. impulse. The current which resets the slave clock drive also releases the impulse mechanism for the master clock thereby avoiding the use of any mechanical connection with the master pendulum other than that of the impulse wheel. As in the case of the slave drive mechanism, the impulse lever makes an electrical contact after delivering its impulse to the master pendulum, which resets the gravity arm and in addition operates the "hit and miss" synchronizer on the slave clock. The slave pendulum normally runs a little slower than the master and is speeded up when necessary by means of a spring attached to the pendulum rod which is engaged by the synchronizer whenever the slave lags

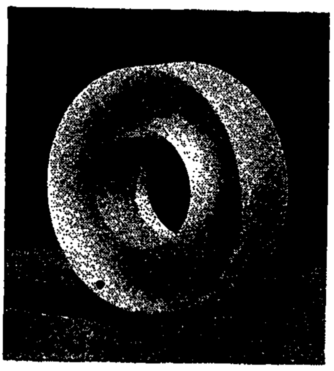

Fig. 3. (Above) Quartz crystal with zero temperature coefficient used in crystal clock

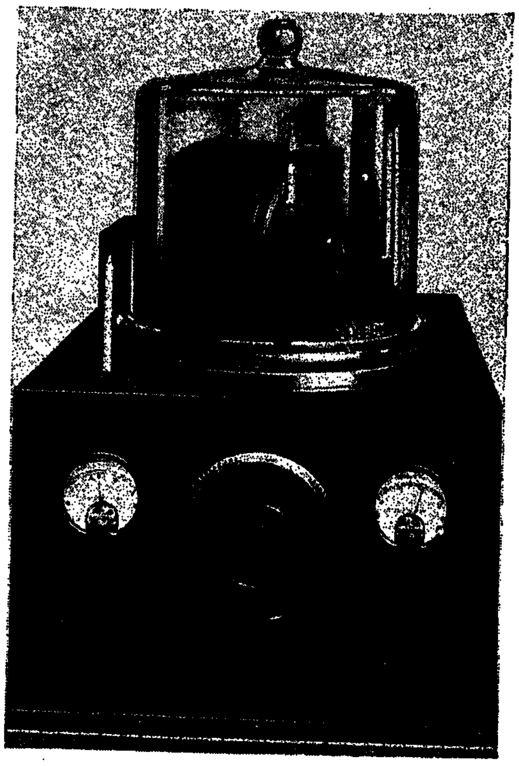

Fig. 4. (Right) Complete 100,000-cycle quartz oscillator

by more than 0.002 sec. behind a definite phase relation to the master.

There are reasons to believe, however, that small changes in phase do occur, especially with variations in amplitude. Probably future improvements in gravity timekeepers will include improved methods for keeping the phase of the driving force more nearly constant.

## CRYSTAL OSCILLATORS AS TIMEKEEPERS

Within recent years developments in methods of keeping time have progressed so far that the constancy of rate of certain mechanical resonators, maintained in vibration by vacuum tubes, may be comparable with that of the best pendulum clocks. Such oscillators have the chief attributes of a good clock and can be used to operate or control a wide variety of time mechanisms with even greater versatility than the conventional pendulum.

The most accurate oscillators of this type known to the authors are controlled by plates of quartz crystal vibrating at a high frequency; that is, high in comparison with the frequency of a pendulum. Probably the most accurate of these at the present time is a set of four 100,000-cycle oscillators that has been built by the Bell Telephone Laboratories principally for use as a primary frequency standard. These laboratories also have supplied a similar set of oscillators for the same purpose to the U.S. Bureau of Standards.

In this type of oscillator the frequency is controlled by a ring of quartz crystal as shown in Fig. 3, about 3 in. in outside diameter. The frequency of the oscillator is the same as that of the crystal; that is, 100,000 cycles per second. One complete oscillator including temperature and pressure controlled crystal and shielded vacuum tube circuit is shown in Fig. 4.

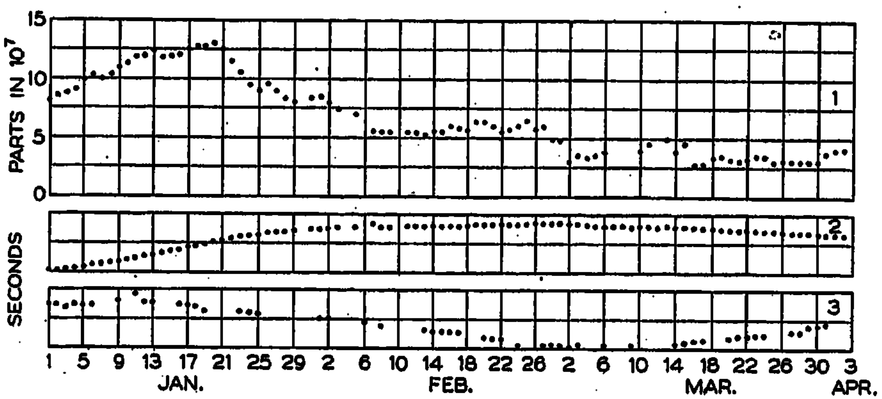

**Fig. 5. Performance data for crystal clocks**

Curve 1. Rate comparison between crystals 1 and 2
Curve 2. Integral of curve 1, showing running comparison
Curve 3. Indicated time of one crystal clock vs. corrected signals from U.S. Naval Observatory

In order to operate clock mechanisms in the most direct way it is necessary to control from this high frequency another which is low enough to operate a synchronous motor. This is done by an electrical circuit known as a sub-multiple generator which controls one frequency at a definite fraction of another in absolute synchronism. Several types of circuit have been used for this, all of which are as positive in action as a set of gears. Usually the low frequency used to operate the motor is 1,000 cycles. Each pole on the motor in motion therefore corresponds to one millisecond in time; hence, any variation in the motor mechanism or operation can amount at most to a fraction of a millisecond. Such a motor can be used to operate time indicating or measuring apparatus in a wide variety of forms.

As a rate controlling element a crystal of quartz used in this way has a number of outstanding useful properties. As previously discussed, the rate of vibration is controlled chiefly by the effective mass and stiffness of the resonator. On account of the chemical stability of the substance $SiO_2$ and the physical stability of the crystal structure of quartz these may be expected to be constant to a high degree. At the present time, variations introduced by the vacuum tube circuit and the crystal mounting are such that no conclusive evidence of aging in the quartz has been obtained.

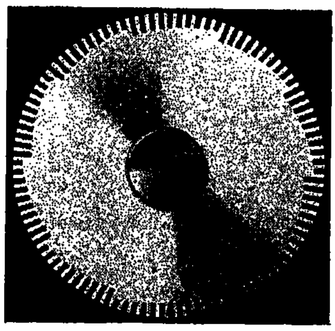
Since the elasticity is a constant for such displacements as are required (amounting to less than one part in 100,000 change of dimensions) the rate is substantially independent of amplitude. The amplitude can be controlled at nearly a constant value, however, by proper adjustment of the vacuum tube circuit.

The temperature coefficient of frequency can be made as near to zero as required at any given operating temperature by properly adjusting the shape of the resonator. Crystals which have been in continuous operation for 3 years have not shown any appreciable change in this adjustment.

Crystals are not affected by gravity or magnetic fields and can be shielded readily from electrostatic fields. They can be mounted so as to be relatively immune to vibrations which always seem to be present in the earth, especially near traveled roads and manufacturing centers. This may be found to be an important factor in the location of accurate clocks in cities or near earthquake zones. The crystals referred to above are mounted on the seventh floor near a much traveled thoroughfare in New York City.

The electromechanical coupling to a crystal for imparting the sustaining energy to it makes use of its piezo activity. As far as has been determined there is no increase in decrement directly due to this means of coupling, although of course through this coupling properties of the electrical circuit such as damping may be manifested in the crystal. The logarithmic decrement of a 100,000-cycle low-coefficient crystal mounted in air at atmospheric pressure and coupled into the electrical driving circuit is about 0.00012.

**Fig. 6. Special light interrupter for the production of accurate timing signals by means of a photoelectric cell**



Probably the largest rate disturbing factors in the crystal clock at the present time are due to effects of the phase $\phi$ of the applied driving force. This factor varies slightly with circuit variables, aging of vacuum tubes, and power voltage variations. Developments now in progress indicate, however, that the effects of these variables can be greatly reduced, and a marked improvement in performance should result. The performance, as clocks, of a pair of crystals is shown for a 3-month period in Fig. 5.

While the crystal clock assembly is more costly than a pendulum clock and requires more elaborate associated electrical equipment, it is believed for many purposes to be decidedly superior because of its great versatility. For example, its rate can be adjusted at will over a sufficient range to allow for such aging effects as occur. Also, the phase, or indicated time, can be adjusted with extreme accuracy. This can be done most advantageously in the electrical circuit by means of a phase shifter which operates continuously through 360 electrical deg., or any fraction or multiple thereof. If used in the 100,000-cycle circuit, one complete turn of the dial corresponds to a final adjustment of 0.00001 sec., which obviously is greater accuracy than needed in any ordinary time mechanism.

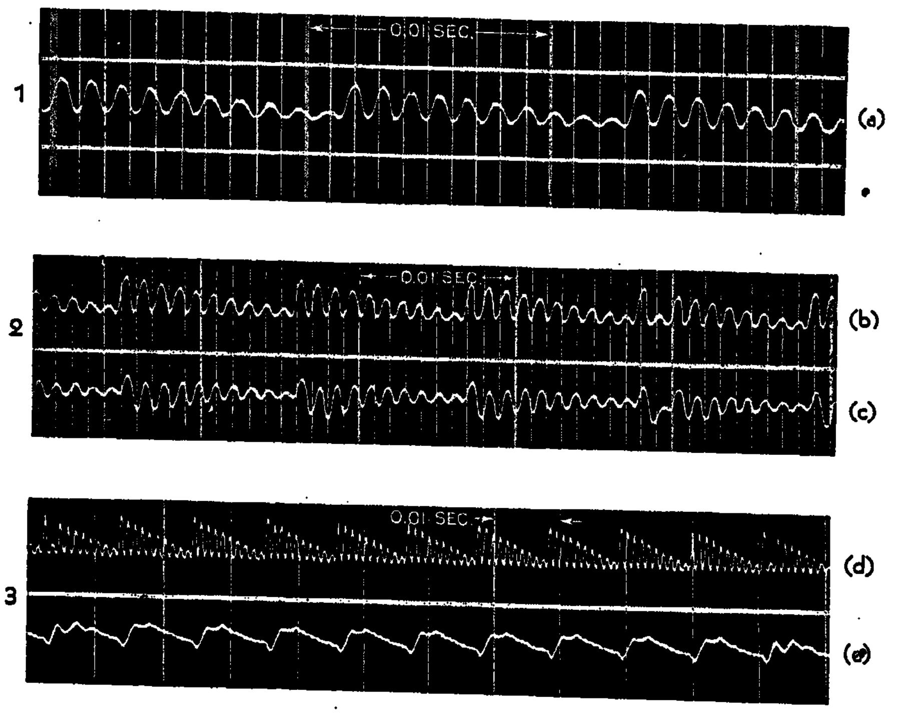


**Fig. 7. Oscillograms of time signals produced by photo-electric cell method**

Oscillogram 1. Direct signal (a) obtained from photoelectric cell
Oscillogram 2. Direct signal (b); and (c) the same signal transmitted by radio. A method is indicated for marking every 0.1 sec.
Oscillogram 3. Direct signal (d); and (e) same signal rectified for recording with only 0.01-sec. resolution

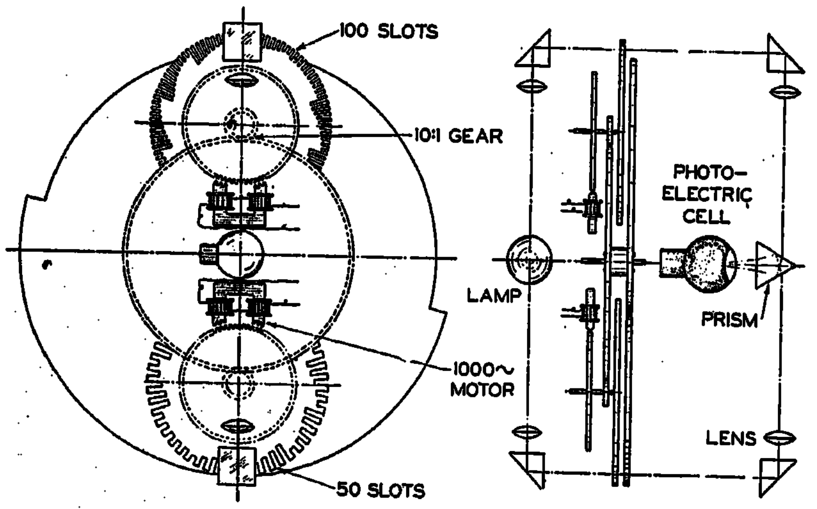

**Fig. 8. Proposed method for production of accurate time signals by photoelectric cells**

The accuracy of inter-comparison of crystal clocks may be very high. An absolute comparison accurate to better than 0.00001 sec. can be maintained continuously, while under special conditions short time comparisons accurate to one part in $10^{10}$ can be made. This high accuracy of comparison is due chiefly to the large number of vibrations per second, 200,000 times greater than with a "seconds" pendulum. Even greater accuracy of comparison could be obtained by the use of higher frequency crystals, but for reasons of convenience and greater freedom from the effect of external circuits and the mounting, the lower frequency is preferred.

One application of considerable interest is that 2 clock mechanisms can be operated from the same crystal control in this way so that one keeps true mean solar time when the other keeps true sidereal time.[9] It can be shown readily that any ratio of rates can be obtained for such a purpose accurate to at least one part in $10^{10}$ without the use of an unduly complicated mechanism. Lord Grimthorp has shown why a pendulum cannot be used for this purpose, but his reasons do not apply to the crystal control method.

By means of a photoelectric cell and a shutter of the type shown in Fig. 6, signals of extreme accuracy can be controlled which could be used for radio transmission of time signals or for any purpose requiring great accuracy. When this disk is rotated at 10 revolutions per second by a crystal controlled motor the current from the photoelectric cell is 1,000 cycles modulated in the manner indicated in oscillogram 1 of Fig. 7, at 100 cycles per second. By marking one 0.01-sec. element, as for example by partially blocking one sector, a positive 0.1-sec. indication is obtained. The oscillograms shown in Fig. 7 were made with the disk shown, and indicate how with the use of a suitable oscillograph, a continuous time signal can be recorded that can be read to a fraction of a millisecond. This resolution would be very useful for accurate time measurement work, for studies in radio propagation times, and for measurements of gravity. Observers requiring less resolution than this could obtain 0.01-sec. accuracy by the use of a rectifier and a recorder accurate to only 0.01 sec. The same is true for 0.1 and 1.0-sec. accuracy by a suitable choice of transmitting disk and receiving equipment.

The second oscillogram shows the signal direct from the disk and after it had gone through a complete radio transmitter and receiver consisting of a total of 11 tandem vacuum tube stages and associated equipment. As indicated, the total delay encountered was about 0.1 millisec., and the distortion is not appreciable. Of course any combination of make and break signals can be controlled in this way using either a continuous or a modulated tone. If desired a series of $^1/_2$-sec. dashes could be controlled, interspaced by a dot-dash code to designate each dash.

A complete time signal control mechanism based upon this idea is shown diagrammatically in Fig. 8. In the method shown, light from a straight filament lamp is imaged on the slotted edge of a disk driven at 10 revolutions per second by a 1,000-cycle motor. The light entering the photoelectric cell is modulated as indicated, at 1,000 times and 500 times per second alternately, and controls a corresponding electrical signal. The slow speed shutter, rotating at one revolution per second, causes the effective light path to alternate between the 2 disks once each second, and gives a corresponding variation of electrical signal. This signal can be used for any resolution from one second down to one millisecond and can be received through static and fading. It can be reduced to the dash-space type by the use of a simple voice-frequency filter to suppress the undesired half signal, or used as a continuous signal for oscillograph recording.

Among the advantages of the crystal clock should be mentioned that in order to control any number of clock mechanisms with the same precision it is necessary only to distribute the constant frequency current derived from the crystal to the separate mechanisms. This can be done on any scale economically feasible.

## EXPERIMENTS IN TIME AT LOOMIS LABORATORY

The clock installation at the Loomis Laboratory, Tuxedo Park, in brief consists of 3 Shortt clocks mounted in an especially favorable location practically free from traffic and electrical disturbances, and carefully temperature controlled. The excellence of the location is enhanced by the fact that the clock vault is excavated in the solid rock of the mountain on which the laboratory stands, and the 3 massive masonry piers for mounting the clocks are effectively a part of this rock. One of the 3 Shortt master pendulums in its casing is shown in Fig. 9 mounted on its pier within the temperature controlled vault.

By means of the Loomis chronograph[8] it has been possible for the first time to obtain a running phase comparison of a number of clocks with great precision. Prof. E. W. Brown and Dr. Dirk Brouwer have shown[10] that the probable error of the mean hourly rates as measured by this chronograph is less than 0.0001 sec. With a resolution of this order, it is possible to study some effects that would be forever unsuspected with the use of any comparison equipment used heretofore.

The rate curves on Fig. 10 will illustrate a case in point. These 3 curves show the differences in rates between the 3 Shortt clocks taken in cyclic order, plotted on a very open scale over a period of about 3 months. Although the mean rates over this and much longer periods are constant to one part in ten million, there are fluctuations in rate having for the most part perfectly definite periods. These fluctuations are real and a study[10] of the data by Professor Brown showed that the periods correspond to the differences in periods of the pendulums taken in pairs. This implies that there is coupling between the pendulums and that the rate of one is modulated by that of the others even though the pendulums swing practically in vacuum and are mounted on separate massive piers, and that they swing in planes 120 deg. apart. This would seem to show that massive as the piers have been made, they are not infinite in comparison with the 14-lb. pendulums, and that strains set up by each pendulum are felt in some degree by the others through the piers and solid bed rock.

A study was made of the performance of several actual installations of precision clocks, including Riefler clocks nos. 60, 70, and 151 at the U. S. Naval Observatory, Washington, D. C.; Riefler clock no. 412 and Shortt clock no. 29 at the Dominion Observatory, Ottawa, Can.; Shortt clock no. 11 at the Royal Observatory, Greenwich, Eng.; Leroy clock no. 1,185 at the Paris Observatory, Paris, France; and Shortt clock no. O at the Royal Observatory, Edinburgh, Scotland. This study showed that although the rate variations of the 3 Shortt clocks at the Loomis Laboratory are quite appreciable as measured by the Loomis chronograph, the relative performance, as clocks, is all that could be desired, and indicates that factors having small but real effects upon the rate can be detected by a chronograph with this high resolving power when they would not be observed at all by ordinary methods. The 3 rate curves and the 3 time curves of Fig. 10 are plotted to the same scale as the corresponding crystal data in Fig. 5.

**Fig. 9. (Right) Master pendulum in casing for one of 3 Shortt clocks located in the Loomis Laboratory**

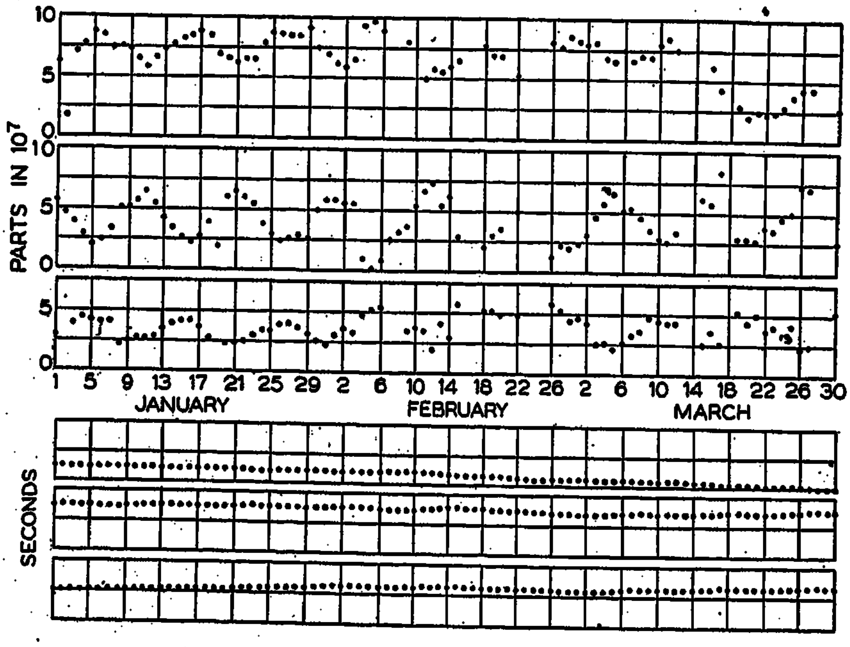
Rates are given in the 3 upper curves. Integrated rates are given in the 3 lower curves



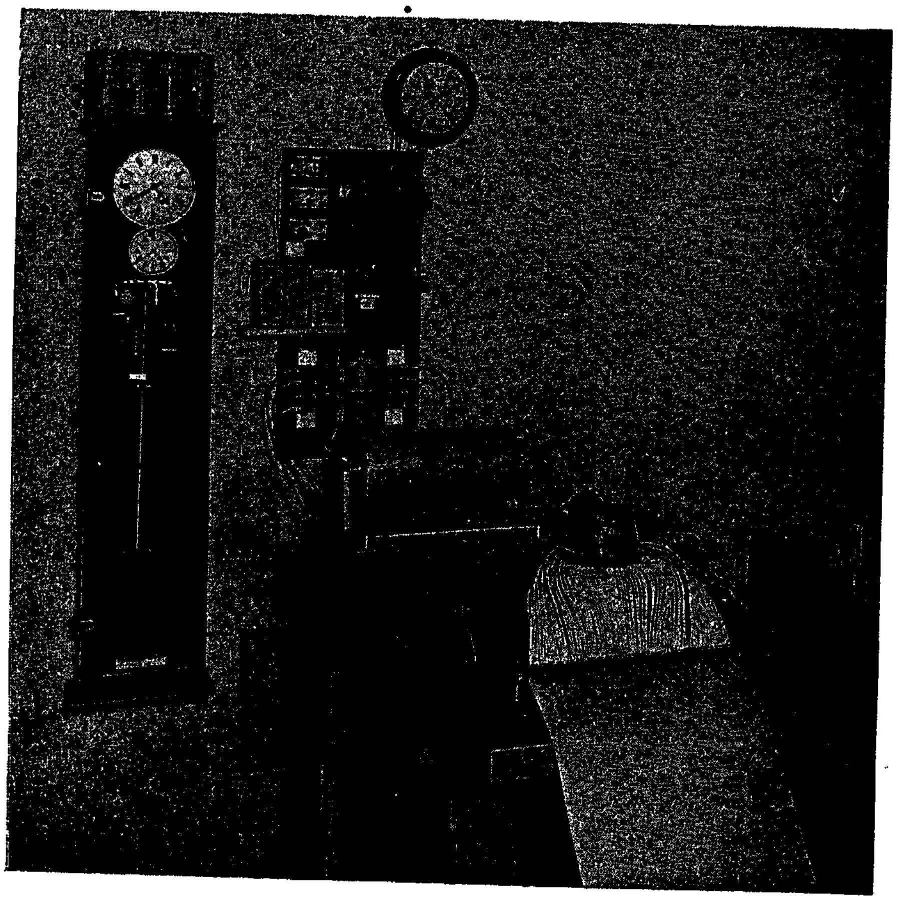


**Fig. 11. Loomis chronograph and one of 3 Shortt slave clocks in the Loomis Laboratory**

The Loomis chronograph shown in operation in Fig. 11 consists of the following essential parts:

1. A strip of paper about 10 in. wide moving at a uniform rate between a long grounded electrode and a comb consisting of 100 separate equally spaced pointed electrodes.
2. A distributor having 100 segments separately connected to the 100 elements of the comb, operated at exactly 10 revolutions per second by a synchronous motor from a source of 1,000-cycle current.
3. A source of high potential consisting of an induction coil through the primary of which a large condenser is discharged when a record is to be made. A small condenser on the induction coil secondary stores sufficient energy to produce an intense spark of very short duration.
4. A single relay in the common circuit of all the time devices to be recorded on the moving paper strip.

If the relay is operated every time the distributor makes some exact whole number of revolutions a series of perforations will be made in a line parallel with the edge of the paper. If in the time between sparks, the motor revolves a whole number of times plus or minus 100, successive perforations will be displaced an amount corresponding to one millisecond in time. One second in time is represented by 10 complete transits of the chart, so that, in effect, the chart is 100 in. wide and the effective recording element moves at the rate of 500 ft. per min. Thus from the slope of the line of perforations with respect to the edge of the paper the difference between the rate of the distributor and the rate of the sparks can be determined with high precision. Similarly any number of separate sets of sparks can be recorded simultaneously on the same chart, using the same actuating relay and distributor. The relative rates may be determined by measuring the difference of slopes of the rows of perforations.

This is the method used for intercomparing the 3 Shortt clocks and for comparing them with crystal oscillators in New York City. To accomplish this, 1,000-cycle current controlled by the Bell Laboratories' crystal is sent over a private wire to Tuxedo and there used to drive the distributor as outlined above. The resulting records are continuous comparisons of the 3 Shortt clocks and the crystal, accurate to better than one millisecond in time.

Since the crystal does not respond to variations in gravity while the pendulum does, the difference in rates contains a term having the period of the lunar day, corresponding to the direct gravitation effect of the moon on the pendulums. Several months' records of the Loomis chronograph have been analyzed[10] by Professor Brown and Doctor Brouwer and a lunar term observed having the proper period and magnitude. A graph of the lunar effect derived in this way is reproduced from their paper in Fig. 12. The periodic gain and loss in indicated time is about 0.0002 sec. per lunar day.

The results of time studies obtained at the Loomis Laboratory have been very encouraging and it is planned to continue the researches in clocks and time measurement methods.

## Possible Future Investigations

No doubt there is a practical limit to the accuracy attainable in a timekeeper but as long as random changes in rate are observed which cannot be explained by uncontrollable properties of matter (such as Brownian movement) that limit has not been reached, even with the types of mechanism at present in use.

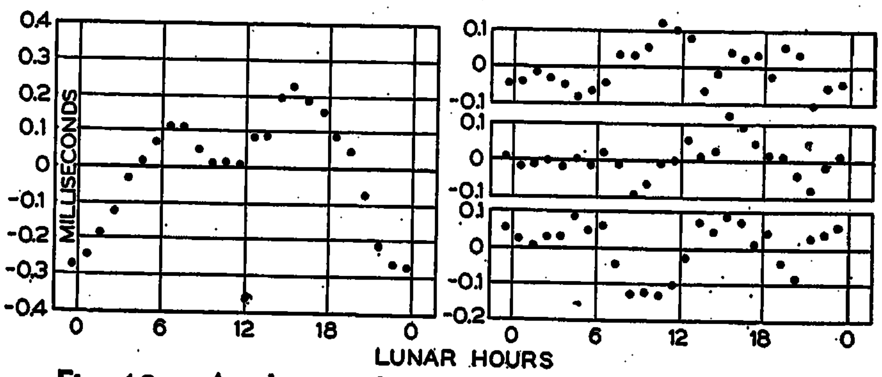

**Fig. 12. Analysis of comparison data between crystal clock and 3 pendulum clocks revealed the periodic lunar day variation shown in the left hand curve**

The suggestion has been made of utilizing the constant velocity of light between fixed points as a measure of period. At present the velocity of light is known to less than one part in a million. Even if it were known with greater accuracy, the practical difficulties of establishing such a standard, except in a very rough way, would be insuperable. In the first place the distance between the measuring points would have to be known to one part in a million, that is, better than 0.06 in. in a mile, assuming no other error, to define a standard good to only 0.1 sec. per day. Considering the difficulties in measurement, an accuracy of a little better than a part in a million is about all that could be expected of such a method by any means now known.

The extreme definition of some spectral lines indicates a very slightly damped oscillation of some sort in the atom, and some thought has been directed to means of making a frequency comparison between these vibrations and others of lower frequency that could be used to measure time as previously outlined. The effective logarithmic decrement of the "oscillator" behind the red line of cadmium can be estimated as about one tenth of that of a quartz resonator. The difficulties of utilizing this sort of thing as a time (or frequency) standard are: First, it is not known at present whether the "frequency" of an atomic disturbance has the same physical significance as vibrations-per-second and, second, even if the significance were the same, the orders of the 2 frequency ranges are so far separated that no means known at present could be used to effect the comparison. Besides, the energy of a spectrum line is no doubt made up of a large number of damped wave trains superposed in some fortuitous fashion as would cover the identity of separate cycles.

Probably the real final limit in the accuracy of timekeepers is concerned with the measure of our time standards. Some observations indicate that the rate of the earth's rotation is not constant, but that there are both systematic and apparently random changes in rate as compared with the motion of other astronomical bodies believed to be more stable. For example: About 1918 a rather abrupt change in rate was observed which amounts to about one part in thirty million. This is small to be sure, but points to the improbability that the rate of any phenomenon is absolutely constant. After all, time is relative and the most nearly accurate measure of time must always be in terms of the most nearly constant motion that can be observed.

At the present time in the official observatories of the various countries the usual procedure is to plot the star observations in terms of their master clock and then to draw a smooth curve, which curve is adopted as the official clock correction. To some extent the drawing of this curve is a matter of judgment, based partly on the number and certainty of the star observations and partly on the estimated performance of the master clock in terms of their other clocks. These observatories at the present time also transmit and record radio time signals and publish periodically corrections to these signals in terms of their "standard clock error." From these data alone it is not possible for any one observatory to compare its clocks directly with the clocks in another observatory. If the observatories would publish one additional number for each of their important clocks, namely, the comparison of each clock with their official time, it would be possible to compare the rates of the clocks in such observatory directly with clocks anywhere else in the world where the radio time signals can be received. This would involve only a very small amount of additional work as the numerical data have to be obtained in any case. It is well to note in this connection that the United States Naval Observatory has adopted a procedure which is very similar to this, the only difference being that instead of publishing the corrections to each of its principal clocks, it publishes a single number which represents the correction of the weighted mean of several clocks. This is an excellent beginning and it is hoped in the interest of future clock developments and of studies in gravity and related phenomena, that others will follow.

Here 2 34.6-kv. lines and 2 communication circuits of the British Columbia Electric Railway Company, Ltd., cross Burrard Inlet; the crossing is designed to carry ultimately 2 165-kv. lines, 4 34.6 kv. lines, and 4 communication circuits. Length of the main span is 1,641.5 ft.; minimum height above high water, 186 ft. Conductors on main towers and back-guys on anchor towers ride on sheaves

# Communication by Police Teletypewriters

Police organizations throughout the country rapidly are adopting the teletypewriter, the latest development in record communication. By this means alarms are typed at one point and simultaneously recorded in printed form at a large number of widely scattered stations. The engineering of facilities required for a modern police system involves the solution of many special problems.

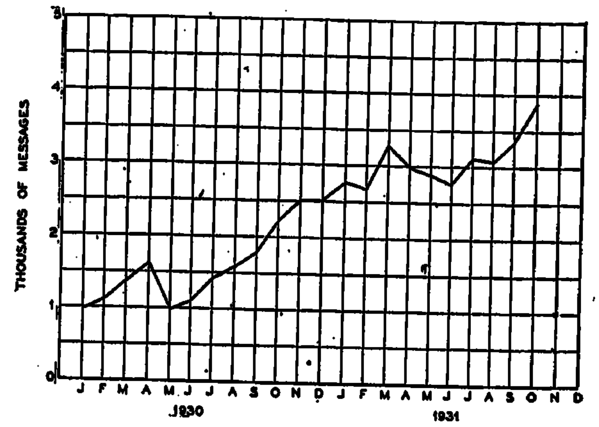

Fig. 2. Traffic on the teletypewriter system of the Pennsylvania state police, in number of messages per month

SPEED, accuracy, and wide coverage are important factors in the communication facilities of any modern police system. During the past 2 years there has been a definite and rapid adoption of private wire teletypewriter systems by the police as a means of communication between the different units within a police organization. The teletypewriter provides means for typing a message at one point and recording the message in typewritten form at a distant point as well as at the home station. These systems are now so widespread that approximately 40 per cent of the people of the United States live in areas protected by police teletypewriter systems.

The primary use of the teletypewriter by the police is to broadcast alarms, usually consisting of notices to apprehend suspects, watch for missing persons, or recover stolen goods. Teletypewriter systems also find a large field of usefulness in the handling of routine correspondence between units of the larger police organizations.

The different types of traffic handled on a typical police system are shown in Table I. These statistics were obtained from the Pennsylvania state police system covering the month of October 1931. The statewide broadcast includes messages from Harrisburg to each of the 110 municipal police stations throughout the state. It will be noted that more than 50 per cent of the statewide broadcasts had to do with stolen automobiles. Since these communications usually involve registration numbers and proper names, the printed record is an important factor in eliminating errors. The rapid growth in the amount of traffic handled by this system since it was established in January 1930 is indicated in Fig. 2.

## General Features

Briefly, the teletypewriter, or printer as it is sometimes called, is a machine which allows a message to be typed simultaneously in 2 or more remote locations. The connections between the various machines on a given network usually consist of ordinary telegraph circuits. If they are long, it may be necessary to provide terminal and intermediate telegraph repeaters in order to obtain satisfactory teletypewriter transmission.

In general, the teletypewriters as used for police communication are arranged to print the received message in page form. The typical machines of this type are shown in Fig. 1. It will be noted that some of the machines are equipped with keyboards while others are for receiving only, and therefore have no keyboards. Power for operating the various mechanisms is provided by fractional horsepower motors which take their current from the local a-c. or d-c. lighting circuits.

The layout of the private wire teletypewriter system of the New York state police is shown in Fig. 3. In this network there are at present 85 teletypewriter stations, 64 of which are arranged for both sending and receiving while 21 are equipped for receiving only. There are 6 switchboards located at the headquarters of the various state police troops. All but one of these switchboards are located in police barracks outside of metropolitan areas. The telegraph circuits involved in this network total about 3,500 miles and require 80 telegraph

---

Based upon "Police Teletypewriter Communication" (No. 32M8) presented at the A.I.E.E. Great Lakes District meeting, Milwaukee, Wis., March 14–16, 1932.

repeaters. Fig. 4 shows a typical telegraph office where provision is made for maintenance and supervision of such private wire systems. The circuit mileage is made up of various types of telegraph facilities, including the voice frequency carrier telegraph system, the metallic telegraph system, 2-path polar and one-way polar system, the polar duplex and the neutral system.

## TECHNICAL FEATURES

The essential elements of the teletypewriter system are: the sending mechanism, the telegraph line, and the receiving teletypewriter. By means of the sending mechanism, manually selected characters of the alphabet and certain necessary typewriter functions, such as paper feeding, carriage returning, and spacing, are converted into groups of electric impulses. These are transmitted over the telegraph circuit by means of different current values, which, as in practically all land line telegraph circuits, are of 2 values. (One of these current values may be zero as in the neutral telegraph system.) The signals set up the selecting devices in the receiving machine corresponding to the transmitted character, and cause this character to be reproduced.

The selecting code which is used employs 5 signal elements for each character. This 5-unit code, in combination with the possibility of either of 2 current values for each unit, provides 32 possible combinations. For instance, representing the 2 current values by (1) and (2) one of the 32 possible combinations would be 1-2-2-2-2. That is, the first unit would be transmitted at one current value and 4 following would be transmitted with the other current value. Another combination would be 1-2-2-2-1, etc.

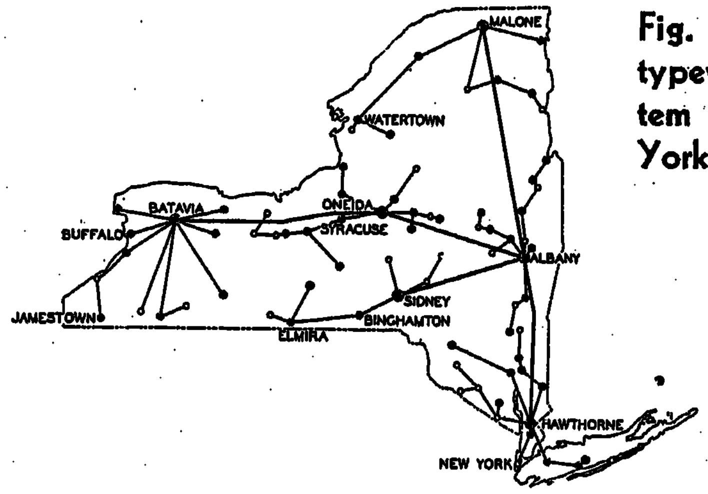

**Fig. 3. Teletypewriter system of the New York state police**

**Table I—Traffic on a Typical Police System in One Month**

| Type of Alarm | Statewide Broadcast | Local Harrisburg Zone Broadcast |
|---|---|---|
| Wanted for crime | 207 | 136 |
| Stolen automobiles | 1,254 | 0 |
| Other stolen property | 36 | 10 |
| Missing persons | 146 | 42 |
| Arrests of wanted | 39 | 38 |
| Miscellaneous | 99 | 543 |
| Recovered automobiles | 700 | 0 |
| Requests for information | 0 | 614 |
| Total | 2,481 | 1,383 |

One of the 5 unit combinations is assigned to each of the 26 letters of the alphabet, leaving 6 remaining for the teletypewriter functions, such as spacing, carriage returning, and paper feeding. Numerals and punctuation marks are obtained by providing 2 characters on each type-bar of the printing mechanism as in an ordinary typewriter, and one code combination is used for shifting from one set of characters to the other. The remaining, or 32nd, selecting combination is employed to allow a receiving station to "break" or stop the sending operator when that station wishes to send.

It of course is necessary to identify each of the 5 successive signal elements at the receiving end, in order that the proper selection be made. This is accomplished by having the receiving mechanism run in synchronism with the sending mechanism. This synchronizing is accomplished without unduly complicated mechanism, by means of the so-called start-stop principle which may be described briefly as follows:

The sending and receiving mechanisms each are driven by fractional horsepower motors running at approximately the same speed, the speeds being controlled either by governors or by the use of synchronous motors. These motors run continuously while the teletypewriters are in use, and through friction clutches drive the transmitting and receiving mechanisms. The transmitting and receiving mechanisms are restrained from operating, however, by mechanical arrangements which are released when the first line signal is received. In order to accomplish this starting function, the 5 selecting signal elements are preceded by a signal element of a current value opposite to that of the line in the idle condition. The receipt of this first signal at the receiving teletypewriter starts the printing cycle. The 5 selecting elements which follow the starting signal select the proper character and cause it to be printed. Following the selecting impulses a seventh signal element is transmitted over the line which causes the receiving mechanism to stop at the completion of the printing cycle. When the next group of signals is received, this cycle is

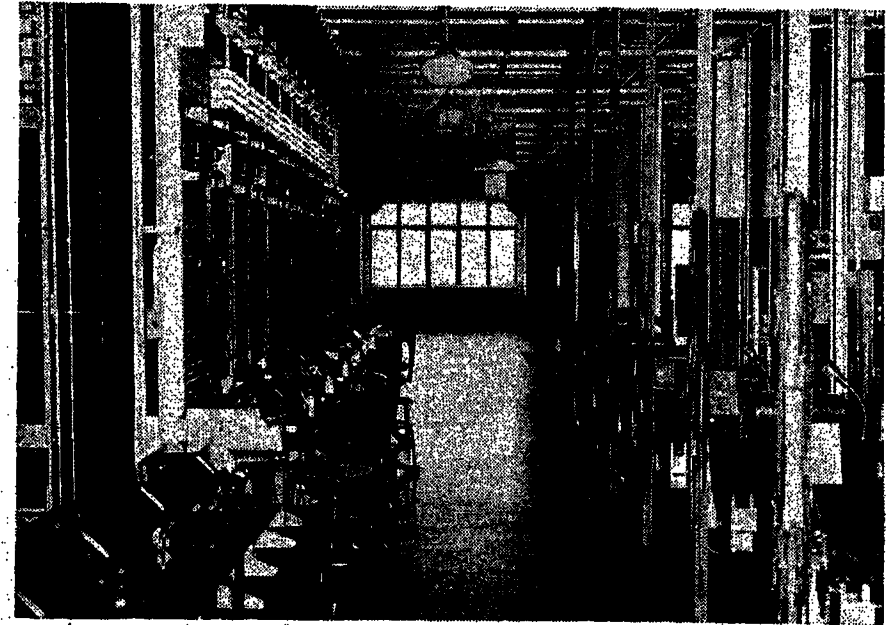

**Fig. 4. Typical repeater office for private wire teletypewriter systems**

repeated. With this arrangement the receiving mechanism does not start until the first impulse is received, and stops at the completion of the cycle. Therefore, the sending and receiving mechanisms are required to remain in synchronism for one printing cycle only. The teletypewriters usually are arranged to type at 60 words per min., or 6 letters per sec. The duration of a printing cycle, therefore, is approximately $^1/_6$ sec., and synchronism is accomplished without rigid requirements on the speeds of the teletypewriter motors.

In addition to simplifying the manner of maintaining synchronism, the start-stop principle makes it possible for 2 stations to communicate without regard to the distance between them or to the lag introduced in the telegraph signals by intervening circuits or apparatus. The selecting signal elements are always transmitted and received in the same time relation to the start impulse which controls the start of the printing cycle.

### SPECIAL FEATURES

Police teletypewriter systems have presented a number of special problems. One of these is due to the fact that the communications are of an intermittent nature, but service must be available continuously. It is therefore desirable that the calling station be able to start and stop the motors of all of the distant called stations. Therefore most police machines are so equipped that starting is accomplished by the sending of a "break" signal and stopping by the sending of a "shift" followed by an "H" signal from the teletypewriter keyboard.

By the use of "shift" signal followed by a letter signal, other features are made available. Teletypewriters thus are regularly provided with a signaling bell. Also in special cases, a loud ringing bell is provided, either a single stroke or a continuous alarm being used.

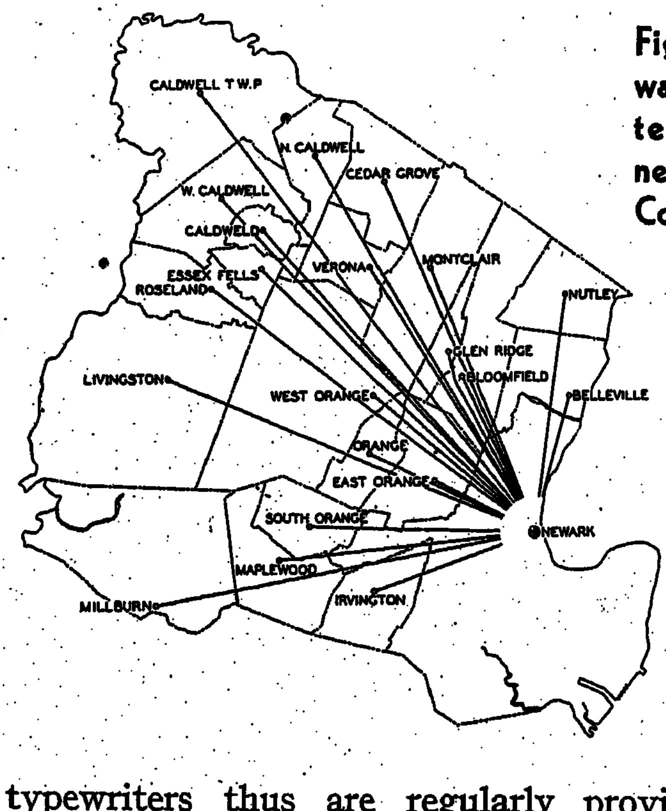

**Fig. 5. The one-way fixed layout teletypewriter network in Essex County, N. J.**

Some of the switchboards used in police systems are equipped with keys for switching, while others have cords and plugs of the type used in telephone switchboards. Since these switchboards are often located in remote places outside of metropolitan areas, it usually is necessary to provide a complete power plant to supply current for line facilities, supervisory signals, and teletypewriter machines.

In some statewide systems the stations are divided into zones, with each zone under the control of an individual switchboard. Arrangements may be provided which allow the operator at general headquarters to take control of the broadcasting circuit for any or all zones throughout the state, thus permitting the statewide broadcasting of certain alarms. The transferring of all the lines from the zone switchboard to sending relays under the control of the circuit from headquarters is accomplished by sending a code signal from a special key at general headquarters over the regular teletypewriter circuit to the zone headquarters. After the statewide broadcast, the circuit may be restored to normal by sending a long "break" signal from headquarters. These operations are accomplished without any action by operators at zone headquarters.

**Fig. 6. Teletypewriter installation at New York City police headquarters. Police Commissioner Edward P. Mulrooney is shown dictating a message during a recent 7,000-mile police teletypewriter hook-up covering the United States and Canada**

In some of the municipal networks, arrangements have been set up whereby a message or alarm sent to an outlying station equipped with a machine for receiving only, can be acknowledged. Usually, a separate circuit is provided for this purpose so that the operation of an acknowledgment key at the receiving station will give a signal, such as the lighting of a lamp at general headquarters. The attention of the receiving station operator may be attracted at the end of a message by the ringing of the teletypewriter bell at all receiving stations.

In a multi-station series network it sometimes is desirable to be able to select stations individually or in groups. For this purpose a selective calling arrangement using a regular telephone dial is used.

When the code number of a particular station is dialed, a selecting device at the station completes the power circuit, thereby starting the motor of the called station. A visible or audible signal will be operated to attract the attention of the operator at the called station, and a busy signal will be lighted at all other stations indicating that the circuit is busy. When desirable, a lock-out or secrecy feature may be provided which prevents any station not called from starting its machine and receiving the message being transmitted. This system has the obvious disadvantage that only one conversation at a time is possible on the network.

### Circuit Layout Features

Various types of circuits are adaptable to police teletypewriter systems. A few of these systems will be described briefly.

The one-way fixed layout system includes a central transmitting point from which communications are transmitted to a number of machines arranged for receiving only. An example of this type of system is shown in Fig. 5. The outstanding advantage of the one-way fixed layout system is the speed with which broadcasts can be made, since the entire network is always available.

The 2-way fixed layout system has all of the stations connected to the circuit so that any 1 can send and the others will receive. The outstanding advantage of this type of system is that the entire network is available to each station for broadcasting alarms or for intercommunication between individual stations. This system has the disadvantage that when 2 stations are communicating, the entire network is not available for a broadcast without interrupting the local conversation.

The one-way selective system consists of lines radiating from a switchboard at general headquarters with machines in the outlying points equipped for receiving only. This is similar to the one-way fixed layout system except that individual lines or groups of lines can be selected.

The 2-way selective switching system can be obtained in either one of 2 methods, or a combination of both. The first method is to provide a central switchboard with lines radiating out to each individual station. The second is to provide more than one station on each line, and to have these stations equipped with the selective calling devices mentioned previously. The advantages of this system are similar to those outlined in the 2-way fixed layout system, but the former has the added advantage that more than one conversation at a time can be carried on between stations in the network.

Many of the police teletypewriter systems combine the one-way and the 2-way features. The first statewide police system to be installed is operated by the state police of Pennsylvania and is of this type. Among other systems of this type is the one in New York City. Of this, the teletypewriter room at general police headquarters is shown in Fig. 6. The switchboard, which has direct lines to 33 precinct stations in Manhattan and to 4 others in borough headquarters, may be seen in the background.

### Exchange Service

When in November 1931 the telephone company offered teletypewriter exchange service to the public, the police departments of the country were among the first to avail themselves of this type of service. The exchange service provides switchboards and trunk line facilities for interconnecting teletypewriter stations at any place in the country. The police department subscribing to this service is provided with a teletypewriter machine with which it may call a teletypewriter exchange operator and obtain a connection with any other exchange teletypewriter station, whether this station is in the same city or in a distant city. This new service provides a nationwide system for interconnecting the various police departments in the country with the same type of record communication which has been so useful in the private wire systems.

# The Effects of Artificial Habits

**Views from a medical college dealing with the effects of engineering progress upon human life add another independent voice to the general discussion of benefits. This is the twelfth article in the Engineering Foundation's symposium, "Has Man Benefited by Engineering Progress?"**

By
A. BACHEM
Professor of Biophysics, University of Illinois, College of Medicine, Chicago

By building tents and huts, by covering the body with fur and cloth, primitive man was able to leave the cave, to expand into the open plain, and to survive in a colder climate; then protection against rain, cold, and storm was rendered complete with the invention of glass, which brought with it a new factor—comfort. All of these measures, first protective, then comfort producing, formed a continuous evolution which led to an artificial change of environment: From the straw apron to the modern apparel, from the primitive hut to the modern apartment house—an evolution which, when expressed biologically and physically, meant but a retreat from light into darkness and from ventilated atmosphere to stagnant air. Prejudices of fashion and custom have but served to fix the results of these developments and to render irreversible this crime against nature, this exclusion of natural stimuli to the skin. The penalty for this transgression is being paid.

### Light Starvation Favors Disease

Lack of ultraviolet rays, unless replaced by a high vitamin D diet, leads to rickets, tetany, and other ills, and predisposes strongly to infections, particularly pneumonia. Light starvation favors certain skin diseases, either directly from lack of stimulation or indirectly by breakdown of the vegetative nervous system and the absence of its coordinative action on the various powers of the body.

One important function of the skin is heat regulation. Heat must be conserved as much as possible in a cool environment, and strongly dissipated in a warm atmosphere. A complicated mechanism serves this purpose: Various stimuli from the skin and from the heat center of the brain affect the internal secretion, the blood chemistry, the blood capillaries of the skin and the sweat glands in such fashion that adaptation to the environment takes place. Operation of this mechanism represents a healthful physiological and psychological exercise for the body: It necessitates chemical and physical work; it requires a coordination of the efforts of the whole autonomic apparatus, which includes the nervous systems, the endocrines and the blood vascular system. The perfect working of this whole mechanism determines to a large extent a healthy constitution. By living in closed rooms and by dressing in heavy and tightly fitting garments, we have allowed this mechanism to cease functioning and its branches to degenerate. The result is that we cannot withstand even small variations of temperature, usually reacting with a cold to even the most moderate exposure. It is the fear of such exposure together with the dictates of fashion that have led the stronger sex so to overdress that their bodies constantly move in a tropical climate.

### Fashion and Science Conflict

Fashion and science now have reached the point where a break may occur unless fashion gives way. It should not be difficult to design a garment without a narrow collar and a tight belt, so that air ventilation is permitted. Disposing of vest and coat should not carry the stigma of social misdemeanor, but should be permitted as a means to allow the body to cool off, to admit some light and to increase its vitality. So long as our mode of dressing is not improved, I see no advantage in the use of windows made transparent to ultraviolet rays or in the use of ultraviolet lamps.

The great development, in recent times, of the building industry, of transportation, and of communication, with the resulting concentration of individuals within cities, schools, churches, theaters, trains, and street cars, has but served to strengthen the gregarious habit of man; this in itself has been shown by statistics to be the prime cause of the prevalence of infectious and contagious diseases. It is these very diseases which the medical man, the sanitary engineer, and the health director find so difficult to combat. That these effects are being realized is evidenced by the efforts of theater owners toward ventilation and temperature regulation of their theaters, and by the increased tendencies of the people to abandon the narrow confines of the city for the more open territory of the suburb. These tendencies have been abetted by the privacy and quickness of the automobile and by the comfort of the radio, together with coming television.

The invention of the machine, followed by its constant modification and improvement to meet the various needs of today, has increased a hundred fold the means for comfort and lessened human labor, and has been heralded as a welcome means to lighten the burden of man. But now the pendulum having swung in the prophesied direction, we have gone from the frying pan into the fire; from the dilemma of too much work we have entered into the morass of idleness. The politician of today has failed to find a remedy for this situation, so let us turn to the views of the biologist.

### Views of a Biologist

In his book, "Studies on Human Biology," Pearl devotes one chapter to the influence of physical activity upon mortality. He bases his deductions on English statistics on the mortality of occupied males more than 15 yr. of age. He divides the 132 occupations into indoor and outdoor work and each of these into 5 groups of increasing activities, from light to hard work. After discussing and eliminating most of the possible sources of error he comes to the following conclusions:

1. Light, medium, and heavy work cause no difference of the death rate between the ages of 15 and about 45 yr. From 45 yr. on, however, hard work increases the death rate, with a strongly increasing ratio for the higher ages. This makes it evident that "before age 40 is attained, it makes no difference in the rate of mortality, whether the occupation involves light or heavy physical labor. After about age 45 it appears that a man shortens his life by definite amounts in proportion as he performs physically heavy labor."
2. Mortality is distinctly lower for outdoor than for indoor workers. This indicates the superior healthfulness of outdoor life.

I should like to add a few generally accepted premises upon which to base a few suggestions of an important social bearing:

1. Work is healthful, mentally and physically, for men and women between 17 and about 45 yr.
2. Many modern professions require too much sedentary life and need outdoor recreation for compensation.
3. Most professions are monotonous; therefore their dulling effects upon the mind should be overcome by recreation that provides mental exercise.

### Better Regulation of Work Needed

Assuming the correctness of these premises one easily recognizes that, because of leaving work and idleness distributed at random, the present system of unrestricted labor and unrestricted unemployment is the incorrect answer to this problem. The only logical measure is to regulate work so much that every man or woman from 17 or 18 up to 45 or 50 yr. old can be provided with work. A 5-day week and a 6-hr. day would suffice for the needs of most countries. The rest of the time can be devoted to healthful recreation. This regulation should be revised periodically according to variations caused by seasons and business cycles. The sick and the old should be protected from destitution by compulsory invalid insurance and old age pensions, or else given a chance to accumulate enough capital to meet such contingencies.

I am convinced that in the adoption of such a scheme lies the opportunity to eliminate the disadvantages of mechanization, and to utilize its benefits in such a fashion as to enable us to live agreeable, healthy lives in greater conformance with the rules of nature and the teachings of modern medicine. It is to be hoped that the present depression will serve as an impetus to give it a trial.

# Analysis of Equivalent Circuits

**Analysis of various circuit problems may be facilitated by the substitution of equivalent circuits which reduce the complexity and permit the replacing of magnetic coupling with simple impedance links so that the calculating board may be used for solution. In this article, general methods of solving the transformer, network, and zero phase sequence problems are presented along with useful diagrams and equations for particular cases.**

By
F. M. STARR
ASSOCIATE A.I.E.E.

General Elec. Co.,
Schenectady, N. Y.

EQUIVALENT circuits are used in the analysis of certain circuit problems. The method consists of replacing the magnetic or electrical system to be analyzed with a simplified equivalent linkage of simple impedance links which satisfies the same terminal conditions. In general, any problem which can be analyzed with an equivalent circuit can be analyzed without it. However, the equivalent circuit may be useful for any or all of the following reasons:

1. Since the equivalent circuit represents only terminal conditions, it is frequently simpler than the actual machine or circuit.
2. The use of the equivalent circuit speeds up and systematizes calculation, in some cases reducing the amount of calculation.
3. The equivalent circuit aids in visualizing the problem.
4. Since the equivalent circuit is made up of simple impedance links, it may be set up readily on the calculating board, thereby lending itself to the solution of complicated networks.

Three closely related types of problems present themselves; namely, the transformer problem, the network problem, and the zero phase sequence system problem. This latter arises primarily through the difficulty experienced in adequately representing on the calculating board, groups of parallel transmission lines in which zero phase sequence currents are flowing. To represent such a group it is desirable to replace it with an equivalent circuit in which mutual impedances between the lines are simulated by simple impedance links. The method of determining such an equivalent circuit is presented in this article following a discussion of the first two types of problems.

The two generalized equivalents discussed under the first two problems are quite broad and should find many applications other than those cited. Only linear circuits and networks are dealt with, however, and in general the circuits developed are equivalent only at a single frequency, although certain ones such as in Figs. 7, 8, and 10 to 13, are equivalent at all frequencies.

## THE TRANSFORMER PROBLEM

In practise, the multi-circuit problem, that is, the problem of a number of circuits each having a self-impedance and a mutual impedance with every other circuit, frequently presents itself. It is usually desired to determine the current in each branch, having given the voltage impressed across each circuit. If the calculating board is to be used in the solution of such problems, the system of coupled circuits must be replaced by an equivalent linkage, since magnetic coupling of adequate flexibility usually cannot be simulated on the calculating board.

Equivalent circuits for the relatively simple case of the two-winding transformer are shown in Fig. 1. In the conventional equivalent circuit of Fig. 1(*b*) all impedances must be expressed on a common voltage

---

Based upon "Equivalent Circuits—I" (No. 32-21) presented at the A.I.E.E. winter convention, New York, N. Y., Jan. 25–29, 1932.

base since the same current flows in each. If $\alpha$ is the ratio of primary to secondary turns, then the values of $Z_1$ and $Z_2$ referred to the primary are, in terms of the magnetizing and mutual impedances (called the characteristic $A$ coefficients):

$$Z_1 = A_{11} - A_{12}a \quad (1)$$

$$Z_2 = A_{22}a^2 - A_{12}a \quad (2)$$

Similar circuits have been developed for the three-winding transformer and the double-winding generator, the value of this type of circuit being discussed in "Theory of Three-Circuit Transformers," by A. Boyajian, A.I.E.E. TRANS., v. 43, 1924, p. 508–29. In the same paper the general equations for setting up a similar type of circuit for the $n$-winding transformer are written. The equivalent circuit of Fig. 1($c$) while still not strictly correct, represents more nearly the actual transformer. In this circuit the short-circuit impedance of the primary is

$$Z = \frac{A_{11}A_{22} - A_{12}^2}{A_{22}} \quad (3)$$

A general equivalent circuit for the $n$-winding transformer having $2n$ points of entry has been derived. This circuit is a mesh composed of $n(2n - 1)$ impedance links, one connecting each point of entry with every other point of entry. The impedance of the link connecting the two points of entry of some winding $j$, i. e., points $j$ and $j'$, is the driving point impedance from point $j$; and the link connecting two points of entry of two different windings, say points $j$ and $k'$ of windings $j$ and $k$, is equal to the transfer impedance between points $j$ and $k'$. These link impedances may be measured directly or calculated from known transformer constants, the $A$ coefficients.

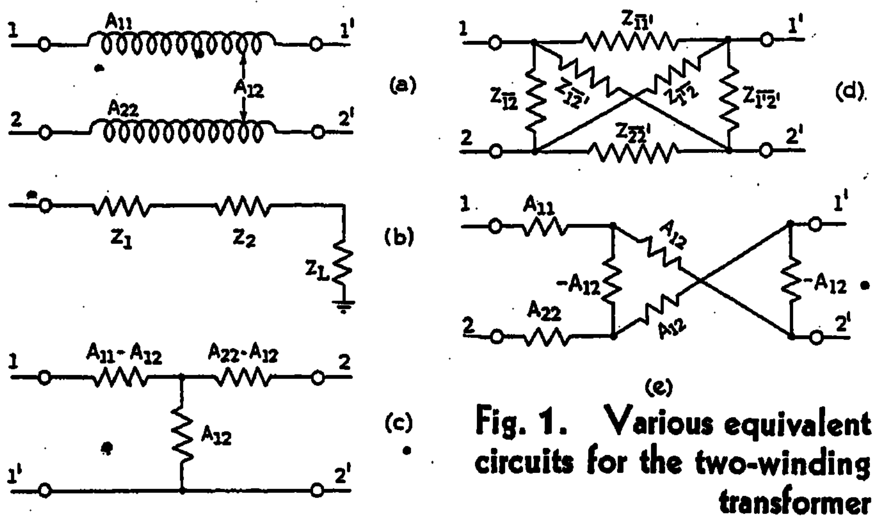

**Fig. 1. Various equivalent circuits for the two-winding transformer**

($a$) The two-winding transformer, in which $A_{11}$ is the primary self-impedance or magnetizing impedance, $A_{22}$ is the secondary impedance, and $A_{12}$ is the mutual impedance between the windings

($b$) Conventional equivalent circuits used for calculating regulation, magnetizing current being neglected. This circuit gives no voltage transformation. $Z_1$ is primary leakage impedance (resistance plus leakage reactance), $Z_2$ is secondary leakage impedance, and $Z_L$ is load impedance, all expressed on a common voltage base

($c$) Equivalent circuit which gives voltage transformation and does not neglect magnetizing current. This circuit must be viewed from one winding only, since it falls down when viewed as a four point network

($d$) A rigorous equivalent for the two-winding transformer which cannot be distinguished from the actual transformer under any imposed terminal conditions

($e$) An equivalent equally as rigorous as that of the Fig. 1(d), but much simpler

The general equivalent circuit for the two-winding transformer is shown in Fig. 1($d$) and is seen to consist of a six-link mesh, the values of which are

$$Z_{\overline{11'}} = \frac{A_{11}A_{22} - A_{12}^2}{A_{22}} \quad (4)$$

$$Z_{\overline{22'}} = \frac{A_{11}A_{22} - A_{12}^2}{A_{11}} \quad (5)$$

$$Z_{\overline{12}} = \frac{A_{11}A_{22} - A_{12}^2}{A_{12}} \quad (6)$$

$$= Z_{\overline{1'2'}} = -Z_{\overline{12'}} = -Z_{\overline{1'2}}$$

Equations defining the links for the equivalent mesh to represent the $n$-winding transformer shown in Fig. 2 have been derived and are as follows:

$$Z_{\overline{kk'}} = \frac{1}{B_{kk}} \quad (7)$$

$$Z_{\overline{jk'}} = \frac{1}{B_{jk}} = Z_{\overline{j'k}} = -Z_{\overline{j'k'}} = -Z_{\overline{jk}} \quad (8)$$

where $B_{kk}$ is the driving point admittance from point $j$, $B_{jk}$ is the transfer admittance between points $j$ and $k$, and $Z_{jk}$ is the impedance of the link connecting any two points of entry $j$ and $k$. The values of these links for the general case may be calculated or measured directly at the terminals of the transformer. The method of measuring transfer and driving-point impedances is well known. The $B$ coefficients are defined by and may be calculated from the following determinantal relations:

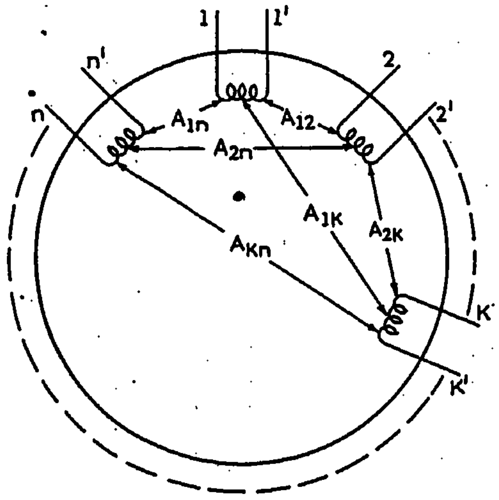

**Fig. 2. A system of $n$ electrically isolated but magnetically coupled circuits**

Such a system may be replaced by an equivalent mesh of $n(2n - 1)$ links connecting each of the $2n$ points of entry in all possible ways. For example of equivalent mesh when $n = 2$, see Fig. 1($d$)

$$B_{jk} = B_{kj} = \frac{Q_{A-jk}}{\Delta_{n-A}}(-1)^{j+k} \quad (9)$$

where

$$\Delta_{n-A} = \left\{ \begin{matrix} A_{11}\, A_{12} \ldots . A_{1n} \\ \cdot \\ A_{k1}\, A_{k2} \ldots . A_{kn} \\ \cdot \\ A_{n1}\, A_{n2} \ldots . A_{nn} \end{matrix} \right\} \quad (10)$$

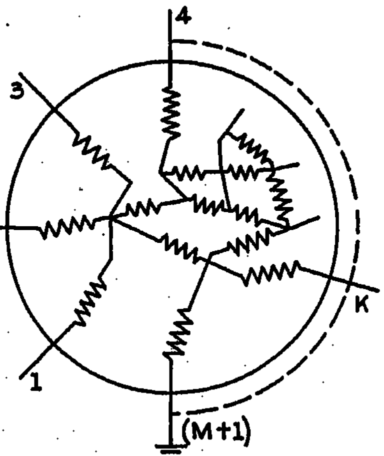
and $Q_{A-jk}$ is the cofactor of $A_{jk}$ in $\Delta_{n-A}$ (i. e., the minor of $\Delta_{n-A}$ with the $j$'th column and $k$'th row deleted) the sign of which is $(-1)^{j+k}$.

The equivalent circuit of Fig. 1(*e*) is seen to be a combination mesh and star arrangement, and may be arrived at by simple reasoning from the mesh of Fig. 1(*d*). Since the self-impedance of any winding is independent of the other windings, its value need not appear in any of the mutual links if it be lumped as a radial link at the terminals of the circuit. Thus, setting $A_{11}$ and $A_{22}$ equal to zero in eqs. 4, 5, and 6, and inserting radial links having impedances equal to $A_{11}$ and $A_{22}$ in terminals 1 and 2, respectively, one will obtain the circuit of Fig. 1(*e*). This latter circuit is much more useful than that of Fig. 1(*d*) since the mutual links are purely reactive, the resistances appearing only in the terminal links. This arrangement avoids the possibility of negative resistance appearing in any link. In an entirely similar manner the mesh equivalent of any number of coupled circuits may be simplified and rendered more useful by reducing to a combination star-mesh arrangement.

## THE NETWORK PROBLEM

In the study of the behavior of a large transmission and distribution system, the transmission lines and connected apparatus commonly are represented by an appropriate single-line diagram, all units of connected equipment being replaced with suitable impedance links. In most cases no trouble is experienced in mapping out the single-line diagram, at least none for the positive and negative phase sequence diagrams, since standard methods are available for doing this.

In setting up the single-line diagram on the calculating board, for purposes of simplification it may be desirable to replace either the whole system or some section of it with an equivalent impedance mesh which has the same number of points of entry but a greatly reduced number of links. For example, Fig. 3 shows a complicated network of impedance links having $(m + 1)$ points of entry. Such a network may be replaced with an equivalent mesh having $\frac{m(m+1)}{2}$ links, one connecting each point of entry with every other point of entry. The equivalent mesh for a five-point network is shown in Fig. 4 (note that $m = 4$ and that for purposes of analysis the $m + 1$ point is considered as a ground point).



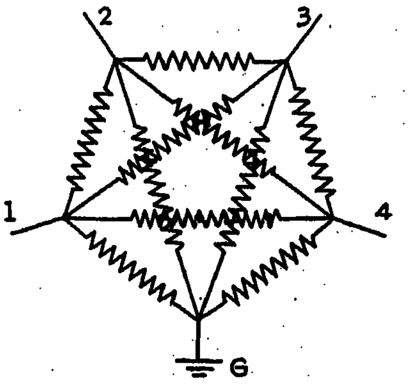


**Fig. 3. (Left) A general network, not simplified**

**Fig. 4. (Right) Equivalent mesh for a network having five points of entry**

The values of the links of the equivalent mesh which is to replace the general network may be determined either by direct calculation from the network constants or by measurements made at the terminals of the network. It may be shown that the impedance of the link connecting any two points of entry such as $j$ and $k$ is equal to the transfer impedance between the points $j$ and $k$, i. e.,

$$Z_{\overline{jk}} = Z_{jk} \tag{11}$$

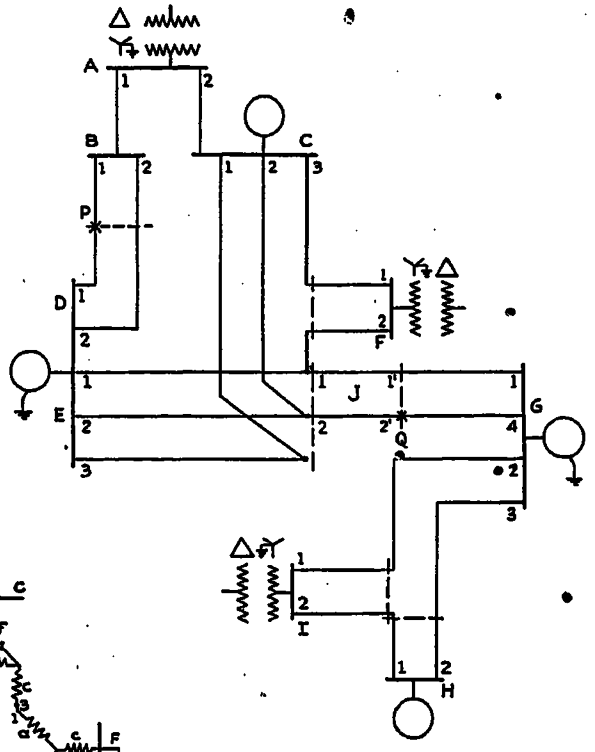

**Fig. 5. (Right) Single-line diagram of a transmission system**

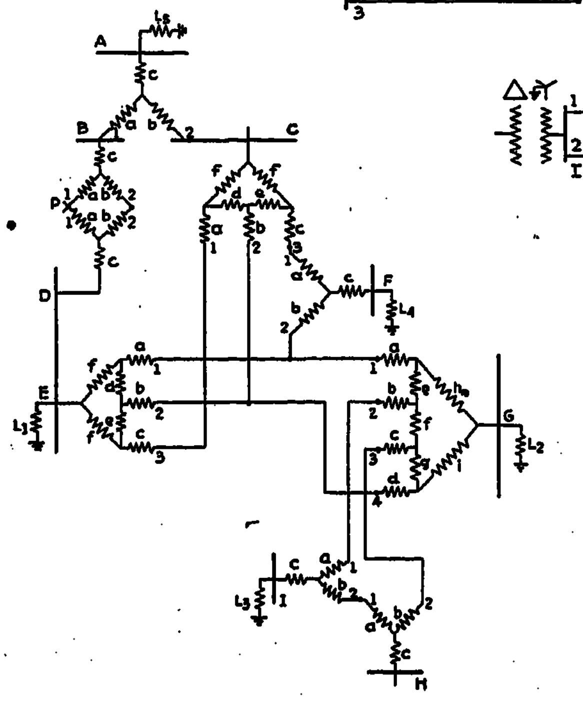

**Fig. 6. (Left) Equivalent circuit for the zero phase sequence diagram of the system shown in Fig. 5 for a ground fault at point *P***

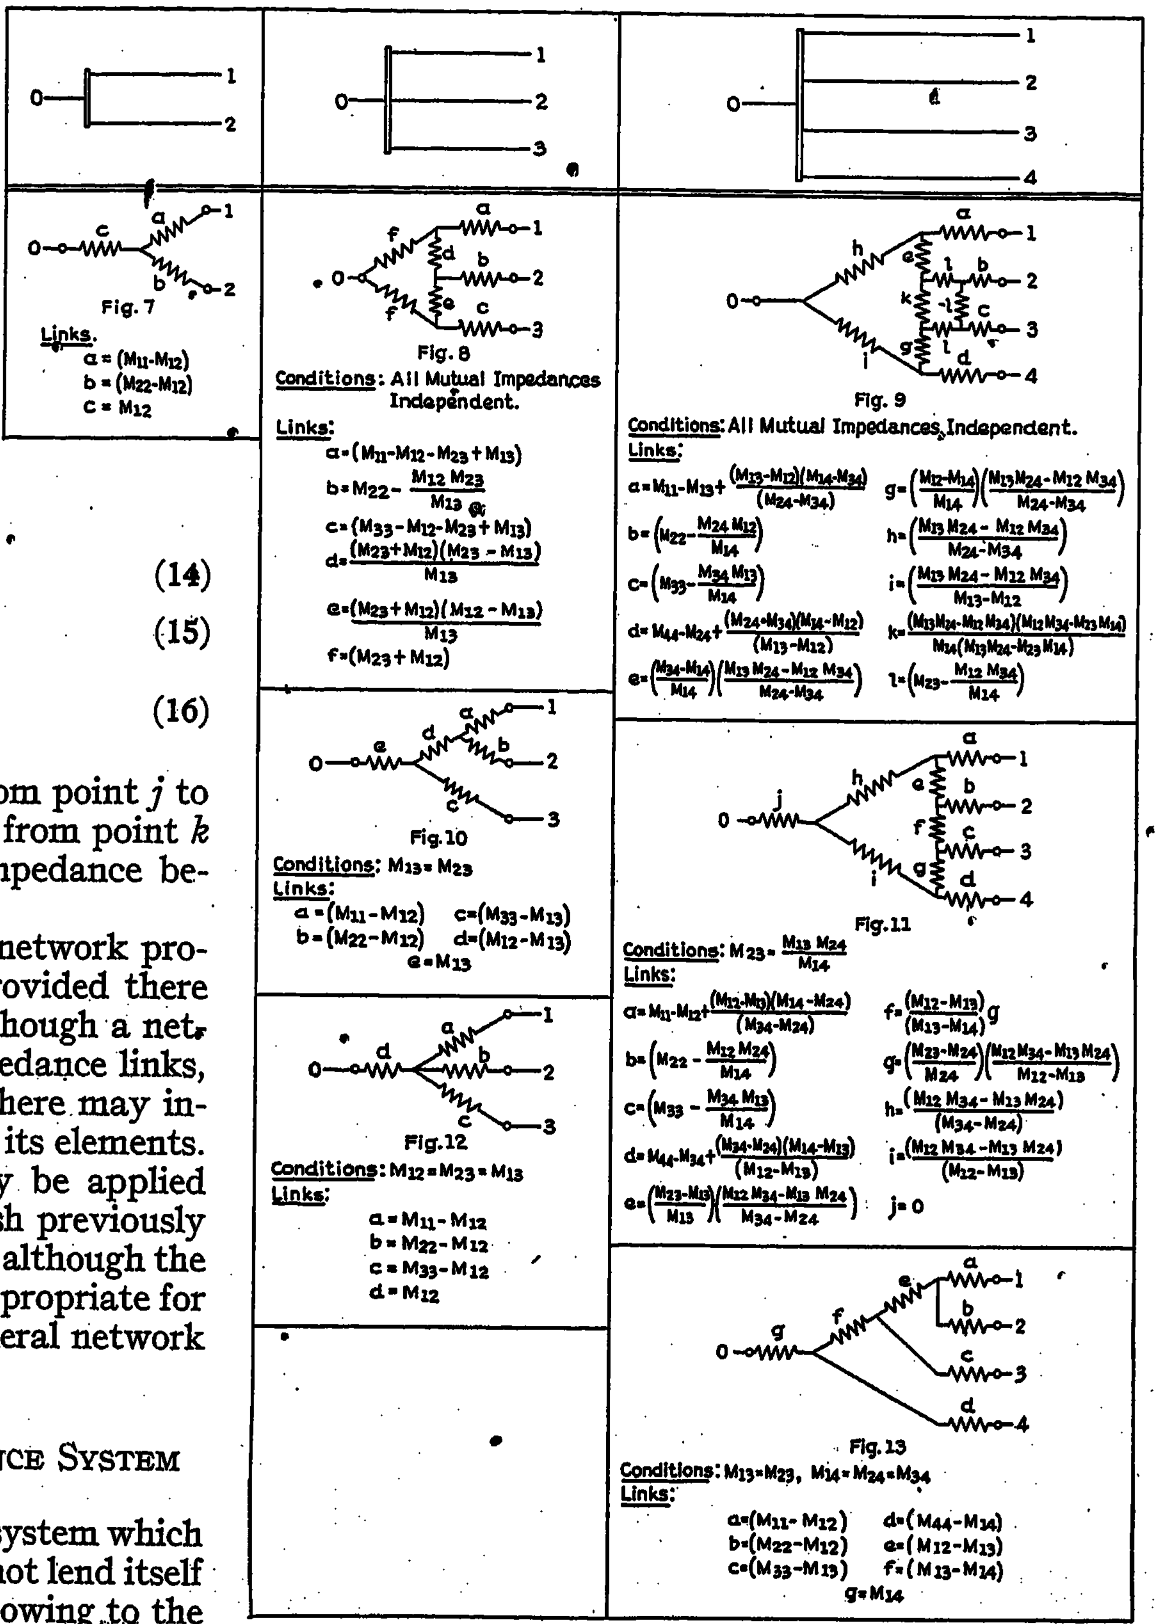
The impedances of the links of the equivalent mesh may be calculated by determinants in terms of the through impedances of the network (by through impedance between any two points such as $j$ and $k$ is meant the impedance between these points with all other points open).

It may be shown that

$$Z_{\overline{jk}} = \frac{\Delta_{m-c}}{Q_{c-jk}} \tag{12}$$

where

$$\Delta_{m-c} = \left\{\begin{matrix} C_{11}C_{12}\ldots\ldots C_{1m} \\ \cdot \\ C_{k1}C_{k2}\ldots\ldots C_{km} \\ \cdot \\ C_{m1}C_{m2}\ldots\ldots C_{mm} \end{matrix}\right\} \tag{13}$$



**Figs. 7–13. From these diagrams, equivalent circuits may be obtained to represent various groups of parallel transmission lines such as shown in Fig. 5 when the zero phase sequence diagram is to be set up on the calculating board**

and $Q_{c-jk}$ is the cofactor of $C_{jk}$ in $\Delta_{m-c}$. The characteristic coefficients of the above determinants in terms of the through impedances of the network are:

$$Z_{jj} = Z_{j-0} \tag{14}$$

$$C_{kk} = Z_{k-0} \tag{15}$$

$$C_{jk} = \frac{Z_{j-0} + Z_{k-0} - Z_{j-k}}{2} \tag{16}$$

where $Z_{j-0}$ is the through impedance from point $j$ to ground, $Z_{k-0}$ is the through impedance from point $k$ to ground, and $Z_{j-k}$ is the through impedance between points $j$ and $k$.

These methods apply to any general network provided the impedances are linear and provided there are no internal voltages. Note that although a network usually is composed of simple impedance links, the general network as it is considered here may involve magnetic coupling between any of its elements. In fact the general network mesh may be applied directly in obtaining the equivalent mesh previously discussed for the $n$-winding transformer, although the latter mesh is much simpler and more appropriate for the transformer problem than is the general network mesh.

## DIAGRAM OF THE ZERO PHASE SEQUENCE SYSTEM

The zero phase sequence diagram of a system which involves parallel transmission lines does not lend itself so readily to a calculating board set up, owing to the fact that when zero phase sequence currents are flowing in the parallel lines, the mutual magnetic coupling between them cannot be neglected; neither can it be represented adequately by the usual calculating board equipment.

A typical example of a system involving groups of parallel lines is shown in Fig. 5. The analytical determination of the currents in every branch of this system due to a ground fault practically is impossible, but if each group of parallel lines is replaced with an equivalent linkage, the calculating board may be applied to obtain an exact solution.

A group of circuits representing two, three, and four parallel lines under various conditions is shown in Figs. 7 to 13, inclusive. Since more than four parallel lines seldom exist for any great distance, equivalents for groups of more than four lines have not been derived; however, should a case arise in which more than four parallel lines do occur, appropriate circuits readily may be developed.

In regard to this special group of equivalents for parallel lines it should be noted that:

1. The values of impedance links are short usable expressions in terms of the self-impedances and mutual impedances of the lines, which are constants usually known.

2. Negative impedance links usually may be avoided in the application of these circuits (the circuits of Fig. 9 being excepted) thereby permitting the use of the d-c. calculating board where resistance may be neglected.

3. The self-impedance of each line appears only in the radial link at the terminal, the mutual links being purely reactive. This arrangement insures that negative resistance will always be avoided.

To illustrate the utility of these special circuits, the system of Fig. 5 is shown in an equivalent form in Fig. 6. Here each group of parallel lines is replaced with an appropriate equivalent. Note that the links of these equivalent circuits are all expressed in terms of the self-impedances and mutual impedances of the lines, $M_{jj}$ being the self-impedance of line $j$ and $M_{jk}$ being the mutual impedance between lines $j$ and $k$. These coefficients are usually known, and if not, they may be readily measured or calculated. The set-up of Fig. 6 may be placed upon the calculating board and used for determining the magnitude and distribution of ground-fault currents for various fault locations, as, for example, at some point $P$, or on any bus.

# Concentration of Heating Currents

**The proximity effect, usually considered as undesirable and wasteful, may be used to concentrate heating currents in predetermined strips of conducting bodies. Both the current density and shape of the strip may be so controlled as to make this method valuable in a number of heating processes.**

By
**EDWARD BENNETT**
FELLOW A.I.E.E.

University of Wisconsin, Madison

ELECTRIC heating currents frequently are used in industrial operations such as welding, forming, and hardening. Where it is desired that the heating be confined to predetermined strips of the conducting bodies, the "proximity" effect may be utilized to control the path of the heating current.

The "proximity" effect, as it is called, is the redistribution of the current densities over the cross-section of conductors which occurs when 2 conductors at first remote from each other are brought into close proximity. Currents flowing in opposite directions in two such conductors cause the current density in the closely adjacent filaments of the conductors to be higher than in the more remotely separated filaments. The less the separation of the conductors and the higher the frequency, the greater will be the variation of the current density. This effect may be magnified to serve a very useful purpose in many industrial heating operations.

Bibliographies of the literature dealing with the distribution of current densities over the cross-section of conductors will be found at the end of the following papers: "Experimental Researches on Skin Effect in Conductors," A. E. Kennelly, F. A. Laws, P. H. Pierce, A.I.E.E. TRANS., v. 34, 1915, p. 1953–2018; and "Bessel Functions for Alternating Current Problems," H. B. Dwight, A.I.E.E. TRANS., v. 48, 1929, p. 820. The second bibliography contains references to papers appearing since the preparation of the first.

The confining of the heating currents to predetermined strips is accomplished by using currents of a frequency in the range known as the audio range, and by the electrical connections and space arrangements illustrated in Figs. 1 to 6. An examination of these arrangements will show that they may be grouped under the following classifications:

1. Current conductively conveyed to the body to be heated.
   a. The shapes and the connections of the heated bodies alone determine the strips in which the current concentrates. See Figs. 1, 2, and 3.
   b. An auxiliary water-cooled conductor is used to determine the strips of concentration. See Figs. 4 and 5.

2. The current is induced in the strip to be heated. A tubular water-cooled inducing coil lies in close proximity to the strip and there is no conductive connection with the body to be heated. See Fig. 6.

In each diagram, the transformer symbol represents the source of audio frequency current. The arrows represent the directions of the currents at a given instant of time. For the sake of clearness it has been necessary to draw the parts with considerable distance between the adjacent edges; but in the actual equipment, this gap is of the order of a few millimeters or centimeters, depending upon the thickness of the edges. The heating currents may be confined to layers ranging in depth from a few millimeters to several centimeters.

The first sight of the red-hot strip of steel conforming to the sinuosities of the water-cooled copper tube mounted above the steel plate illustrated in Fig. 5 is found to be somewhat startling even to engineers who have witnessed the heating effects obtained with the arrangements shown in Figs. 1, 2, and 3.

In all of the arrangements illustrated in these figures, the control over the pattern according to which the current densities are to decrease from the center line to the edges of the selected strip and from the surface of the strip to the interior of the body is had by the joint adaptation of 3 things; namely, the frequency of alternation of the heating currents,

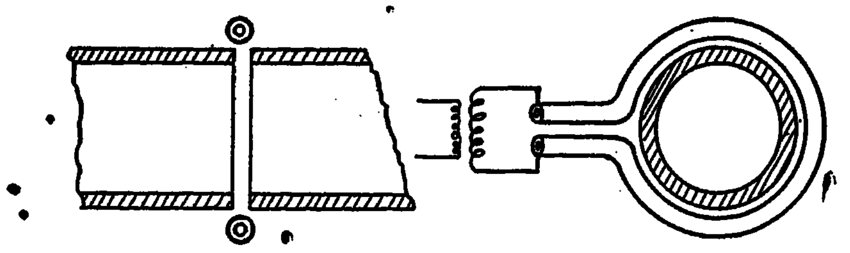

Fig. 6. Strip heating by an inducing coil

Table I—Values of the Penetration Unit

| Material | Temp. °C. | Relative Resistivity | Relative Permeability | Frequency | Conductivity mho-cm. | P. unit cm. |
|---|---|---|---|---|---|---|
| Copper | 20 | 1 | 1 | 960 | 580,000 | 0.214 |
| Steel | 20 | 11 | 100 | 960 | 52,700 | 0.070 |
| Steel | 800 | 94 | 1 | 960 | 6,240 | 2.06 |
| Steel | 1,300 | 100 | 1 | 960 | 5,800 | 2.14 |
| Earth | | $5.8 \times 10^9$ | 1 | 60 | $10^{-4}$ | 65,000 |

the distance from the surface of the strip to the second conductor, and the width and cross-sectional shape of this second conductor. A high-frequency, a short distance between the surface of the strip to be heated and the second conductor, and a narrow second conductor lead to the concentration of the heating current in a narrow strip.

In dealing with the distribution of alternating currents over the cross-section of conducting bodies, it is very helpful to express all linear dimensions, not in centimeters but in terms of a unit of length appropriate to this problem. This unit of length may be called the "penetration unit" for the material at the frequency in question. The advantage of using this unit is that it makes possible the representation, by a few curves, of the distribution of the current for a wide range of conducting materials, spacings, and frequencies.

The length of the penetration unit is,

$$1\ P \text{ unit (penetration unit) (in cm.)} = \frac{1}{\sqrt{\pi f \mu \gamma}} \qquad (1)$$

where

$f$ represents the frequency

$\gamma$ represents the conductivity of the conductor in mho-cm.

$\mu$ represents the permeability of the conductor in weber ampere-turn cm. units. ($\mu = 4\pi 10^{-9}$ for non-magnetic materials.)

The values of the penetration unit for different materials and frequencies are as shown in Table I.

In order that a physical significance may attach to the penetration unit as defined in eq. 1, the following statements may be noted. The effective resistance to an alternating current of frequency $f$ of a conductor of circular cross-section, the radius of which is 5 or more times the penetration unit of the material at the frequency $f$, is approximately equal to the ordinary ohmic resistance of a surface layer of the conductor having a depth equal to the penetration unit. Again, at a depth of 1 penetration unit below the surface of such a large conductor, the current density is approximately 36.8 per cent of the density at the surface, and it lags by 1 radian behind the current density at the surface.

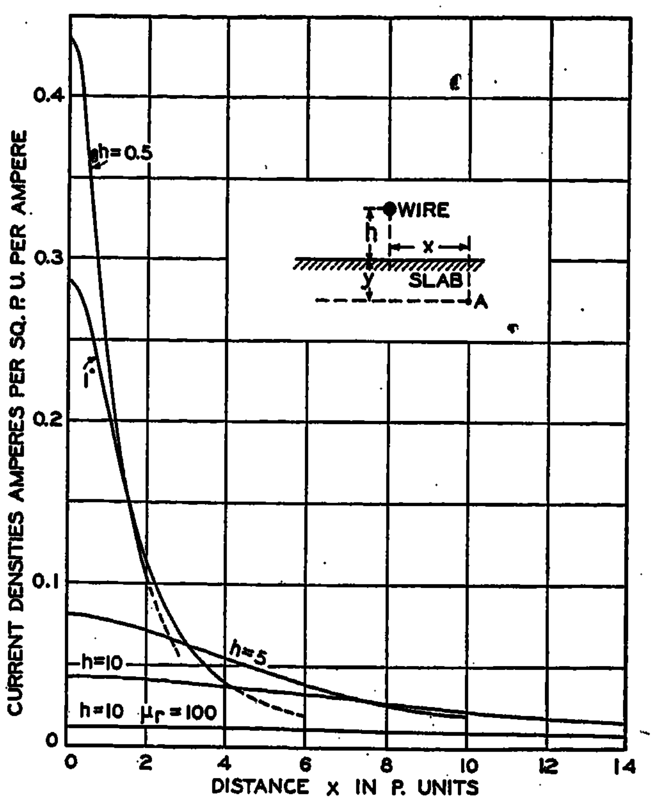

Fig. 7. Current densities at the surface of a slab for different mounting heights

Current densities are expressed in amperes per sq. penetration unit per ampere of heating current flowing in the auxiliary conductor. The distances $x$ and $h$ are expressed in penetration units

To illustrate the extent to which heating currents can be caused to concentrate in narrow strips by enhancing the proximity effect, the current densities have been worked out and plotted for the arrangement illustrated in Fig. 5, except that the auxiliary conductor has no sinuosities but is in the form of a long straight wire mounted over a wide conducting slab of a thickness 5 or more times the penetration unit of the material at the operating frequency. The radius of the auxiliary conductor has been assumed to be very small in comparison with its mounting height, $h$, say 5 per cent or less.

The current density $C$ at any point $A$ in the slab may be computed from the following Fourier integral.

$$C = \frac{j\,2\,I}{\pi} \int_0^\infty \frac{1}{\sqrt{b^2 + 2j} + b\mu_r} \cos xb \exp(-\,hb - y \sqrt{b^2 + 2j})db \qquad (2)$$

where

$C$ represents the current density at $A$ in amperes per sq. Pen. unit

$b$ represents the variable of the integrand. It disappears from the integral upon substituting the two limits 0 and $\infty$

$I$ represents the value of the heating current in amperes

$h$ represents the height of the auxiliary conductor above the surface

$y$ represents the depth of the point $A$ below the surface

$x$ represents the $x$ coordinate of the point $A$, as shown in Fig. 7

$\mu_r$ represents the relative permeability of the conducting slab

$j$ represents $\sqrt{-1}$

exp $(-hb)$ represents the exponential series in $(-hb)$. (The values of $x$, $y$, and $h$ are to be expressed in $P$ units.)

Eq. 2 is valid for materials and frequencies in which the conduction current density is 100 or more times as great as the displacement (charging) current density. For copper at a frequency of 1,000 cycles per sec., the conduction current density is $10^{15}$ times the displacement current density.

If the slab is of non-magnetic material, or of ferromagnetic material at temperatures above the point at which the material becomes non-magnetic, $\mu_r$ has the value unity, and eq. 2 reduces to the following form which is equivalent to that given by J. R. Carson in "Wave Propagation in Overhead Wires With Ground Return," *Bell System Tech. Jl.*, Oct. 1926, p. 539–54.

$$C = \frac{I}{\pi} \int_0^\infty [\sqrt{b^2 + 2j} - b] \cos xb \exp (- hb - y \sqrt{b^2 + 2j})\, db \qquad (3)$$

For mounting heights for the auxiliary conductor in which $h$ is greater than 20 penetration units, eq. 3 for non-magnetic materials evaluates to the simple form

$$C = \frac{1 + j}{\pi} \frac{h}{h^2 + x^2} (\exp - y) (\cos y - j \sin y)\, I \qquad (4)$$

An examination of Table I will show that the value of the penetration unit for steel at a frequency of 960 cycles per sec. lies between 0.07 cm. for steel with an assumed relative permeability of 100 and 2.14 cm. for steel at a temperature of 1,300 deg. cent. For an auxiliary conductor mounted at a height of 1 cm. above the conducting slab, the important range of mounting heights for this steel would lie between $h = 0.5$ and $h = 20$ penetration units.

In Fig. 7 are contained curves, each worked out for a different mounting height of the auxiliary conductor, which show the manner in which the current density at the surface of the slab falls off on each side of the center line of the heated strip. All the curves have been plotted for material in the non-magnetic state save the curve marked $\mu_r = 100$, in which the relative permeability has been taken to be 100. The effect of the permeability of the steel in confining the current to a thinner surface layer of the steel and thereby causing a wider spread of the current is to be noted.

A mounting height of one penetration unit means that the height of the auxiliary conductor above the slab would be about 2 cm. for a steel slab with a strip at its welding temperature and a 960 cycle heating current. For this important case, Figs. 8 and 9 show the distribution of current densities at the surface and at points in planes located at depths of 1 and 2 penetration units below the surface. These figures also show the phase of the current density at these points, relative to the phase of the total heating current. The current density along the center line of the strip is seen to be 60 deg. in advance of the total current. At points in planes 1 and 2 penetration units beneath the surface, the current density lags substantially 1 and 2 radians behind the current density at corresponding points on the surface, and has decreased to roughly $(1/\epsilon)$th and $(1/\epsilon)^2$ of its value at the surface. In the surface at a distance of 2 penetration units from the center line of the strip, the current density is seen to be 40 per cent of the value on the center line, and thus the power expenditure per unit volume is only 16 per cent as great as along the center line.

The relative effect of close proximity of the auxiliary conductor and of a high frequency of alternation in contributing toward the concentration of the heating currents in narrow strips is brought out more clearly by plotting the current densities at the surface against the ratio of the distance $x$ of the filament to the mounting height $h$ of the auxiliary conductor, as in Fig. 10.

## Economic and Practical Features

A number of important questions of an economic and practical nature remain to be solved before the

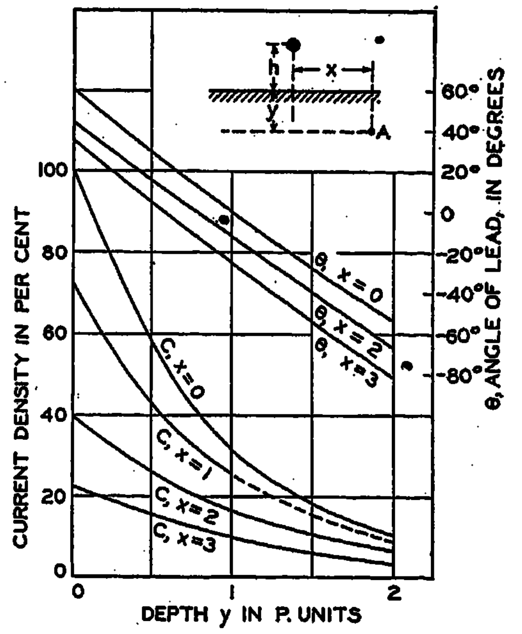

**Fig. 9. Current densities and phase angles for a mounting height of one penetration unit**

The current densities are given in per cent of the current density directly below the wire. $x$, $y$, and $h$ are in penetration units. The phase angles are the angles by which the current density leads the heating current

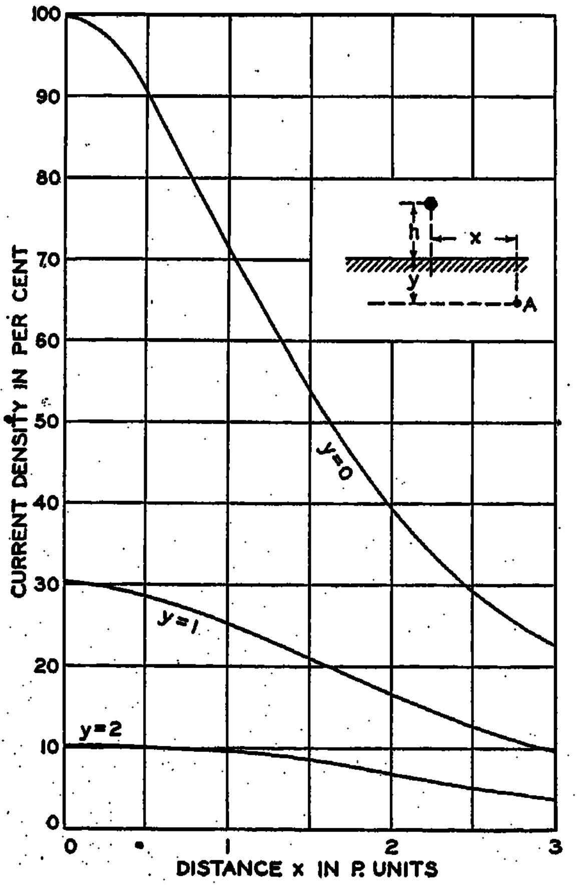

**Fig. 8. Current densities for a mounting height of one penetration unit**

The current densities are given in per cent of the current density directly below the wire. $x$, $y$, and $h$ are in penetration units

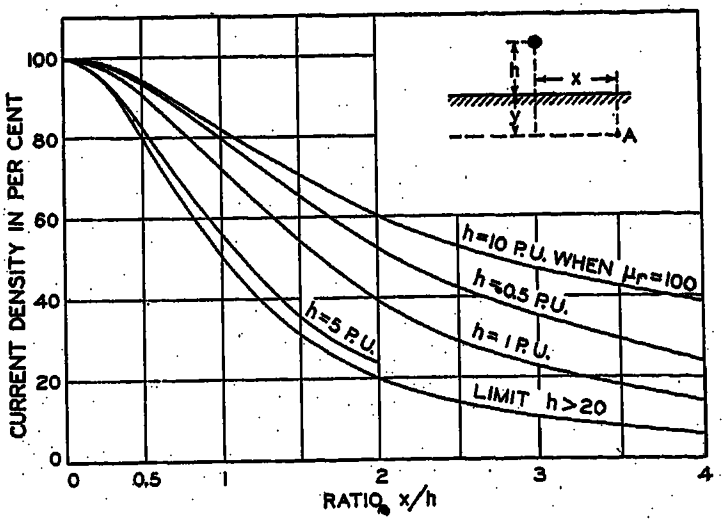

**Fig. 10. (Right) Current densities at the surface of a slab**

For each height of wire, the current densities are expressed in per cent of the current density existing immediately under the wire at that height. The distance $h$ is expressed in penetration units practise of selective heating, by means of the proximity effect, can be established as a shop process. The experiments upon which this article is based have been limited to the experience to be had with a condenser mercury-spark-gap source of high frequency currents having a rating of 35 kw.

The most economical range of frequencies for use in the process remains to be determined. Many factors which vary from operation to operation, such as the kind and size of material to be heated, the nature of the desired temperature pattern, and the relative cost of generating energy at the different frequencies will serve to determine the range of frequencies which will be the most economical. Present experience would indicate that the economic frequencies may be expected to center upon 960 cycles per sec.

Unquestionably the control of the distribution of heating currents which is made possible by the application of the proximity effect opens up a new range of industrial heating effects. It is possible to raise the temperature of a predetermined strip a few millimeters deep in a conducting plate to reach a welding temperature, while portions of the plate a few centimeters away may be substantially at room temperature. On the other hand, more gradual changes in temperature also may be secured if desired. A hitherto unattainable nicety of control of the distribution of temperatures in bodies is made available by the application of the proximity effect.

# Conductor Vibration on Transmission Lines—II

**Field tests substantiate the results of theoretical and laboratory investigations of conductor vibration on electric power transmission lines treated in an article appearing in the July issue of ELECTRICAL ENGINEERING. Among other important findings it is shown that adequate practical protection against damage from conductor vibration can be provided by the proper use of armor rods or dampers.**

Both of the Aluminum Company of America, Pittsburgh, Pa.

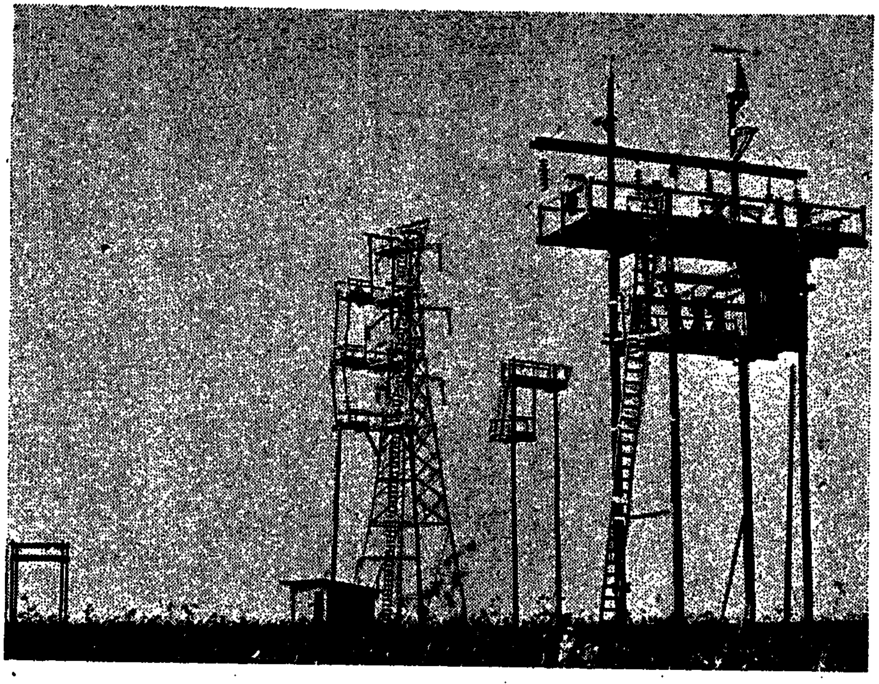

Fig. 8. Observation structures for field tests, Royse City (Tex.) experiment station

FIELD OBSERVATIONS of conductor vibration on operating power lines in various parts of the country have been coordinated with laboratory research. Early in 1930 it was decided to establish a field laboratory equipped for accurate study; accordingly a station was established near Royse City, Texas, about 35 miles east of Dallas. Chief among the considerations which led to the selection of this site were the flat unobstructed topography and the remarkably steady wind conditions. A vacant position on an existing steel tower line was made available for experimental work by the Texas Power and Light Company and additional spans were erected on wood H-frames at nearly a right angle to the existing line. This site has proved to be excellent, for hardly a day has passed without vigorous vibration being recorded on at least 1 of the 2 test lines.

In addition to the field studies at Royse City, observations have been conducted on operating lines as follows:

1. The Public Service Electric and Gas Company of New Jersey 220-kv. Roseland-Bushkill line; 795,000-cir. mil A.C.S.R. conductor and 203,000-cir. mil A.C.S.R. ground wire.
2. The Pennsylvania Power and Light Company 220-kv. Plymouth Meeting-Siegfried line; 184,000-cir. mil ground wire.
3. The Idaho Power Company 132-kv. Caldwell-Ontario line; 4/0-A.C.S.R. conductor.

Engineers of the New England Power Company have observed that under certain conditions a charged conductor tends to vibrate, presumably from the effect of corona. While allied to the general problem of conductor vibration the occurrence of vibration of this sort is probably rare. The Pacific

Gas and Electric Company has made field observations of conductor vibration, and also laboratory experiments[9] on vibration dampers. Space limitations, however, prevent including more than reference to the experimental work of these and other companies.

## ARRANGEMENT OF TEST EQUIPMENT

At Royse City two test lines are available at an angle of 74 deg. thus insuring one line being favorably exposed for vibration regardless of wind direction; span lengths are 650 and 1,225 ft. on the steel towers, and 416 and 1,226 ft. on the H-frames. The ground wire on the steel towers is $^3/_8$-in. diameter 7-strand steel, while the conductors of the 132-kv. circuit on the towers are 4/0 A.C.S.R. (aluminum cable steel reinforced) equipped with armor rods. Other sizes and special types of conductors have been installed and observed for short periods. Conductor tensions are adjustable at the anchorages. General arrangement of the observation towers, which extend 12 ft. out under the conductors, may be seen in Fig. 8.

A satisfactory instrument for obtaining 24-hour vibration records was made by using an 8-inch diameter wax-coated, clock-driven chart on which the vertical motion of the conductor was recorded by a stylus attached to a pivoted arm. (See Fig. 9.) For small conductors the inertia and friction of the pivoted arm damped the vibration considerably; therefore a very light stylus attached directly to the cable was substituted. This latter arrangement, however, is satisfactory only if longitudinal motion of the conductor is restrained.

A continuous record of wind direction and velocity was obtained by an anemometer which records electrically the passage of each mile of wind on a strip chart, and a weather vane with a cam-actuated pen which records direction simultaneously on the same chart. The velocity for short periods was determined with a stop-watch and buzzer which indicates $^1/_{60}$ of a mile.

The frequency recorder consists of a uniform-speed motor-driven strip chart on which a trace of the vibration is recorded by a pencil connected to the line by a cord and spring. In addition to the foregoing, a thermograph was used to record temperature, and provision was made for observing sag and tension in the conductors.

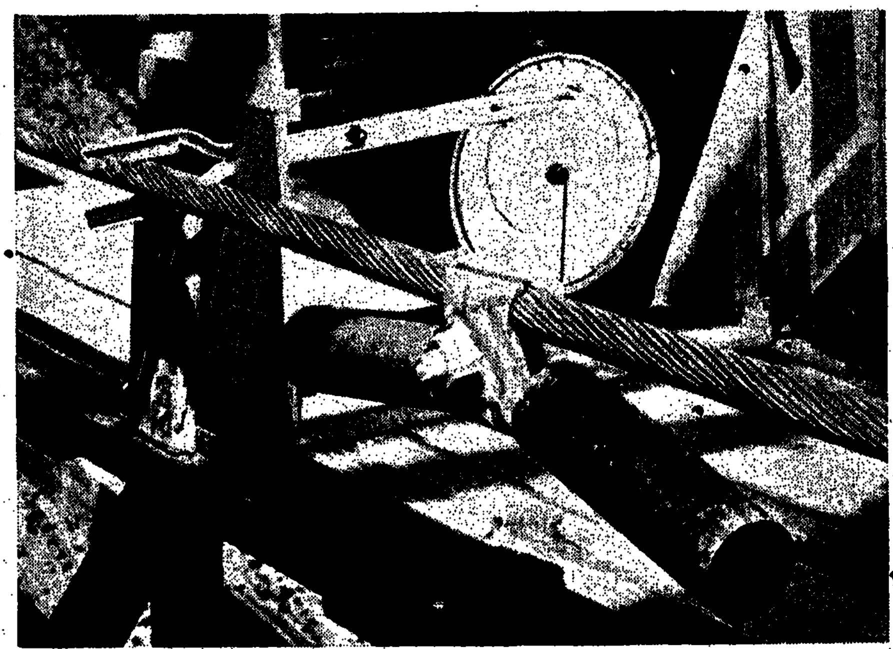

Fig. 9. Conductor vibration recorder

## THEORETICAL CHARACTERISTICS OF VIBRATION

In Fig. 10 is given a graphical solution of eq. 1 ("Conductor Vibration on Transmission Lines—I," ELECTRICAL ENGINEERING, July 1932, p. 482–7). This shows the theoretical relations between frequency, loop length, tension, and weight of a vibrating cable for common conductor sizes and tensions. A formula expressing theoretical frequency of vibration developed experimentally by Relf and Ower ("The Singing of Circular and Stream Line Wires," Aeronautical Research Committee *Report No. 825*, March 1921) is as follows:

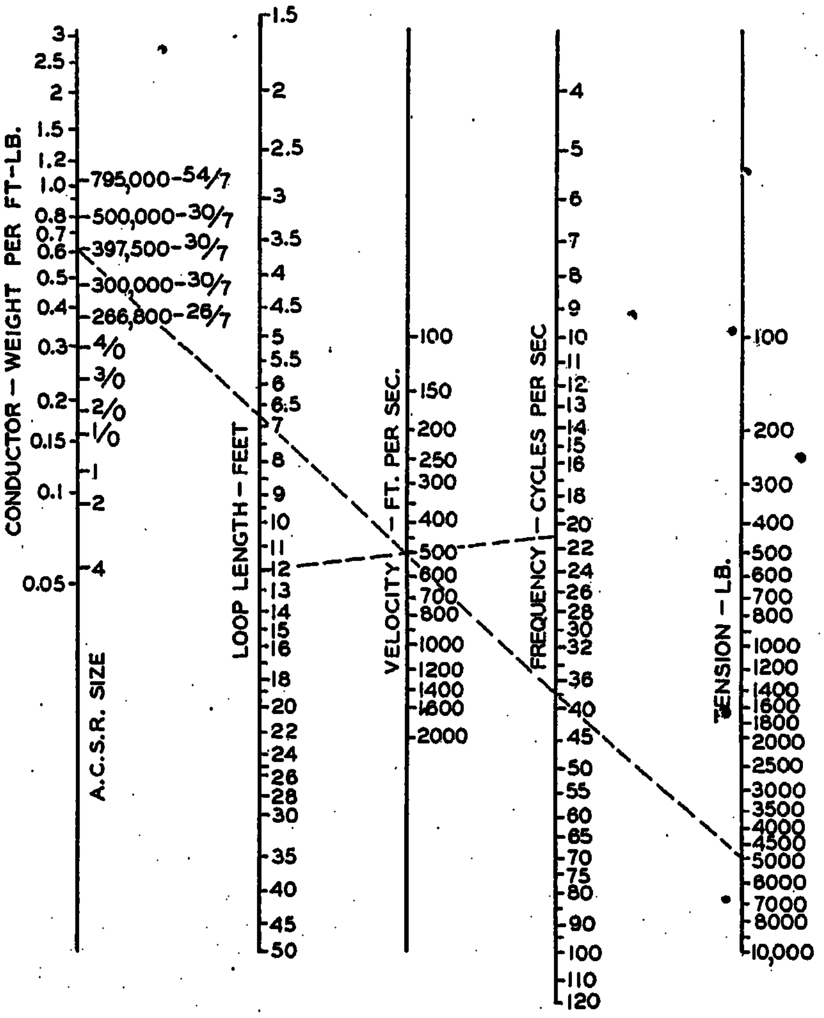

Fig. 10. Relation between weight, tension, loop length, and frequency of a vibrating cable

$$f = k\frac{V}{D} \qquad (14)$$

where

$V$ = velocity of wind in mi. per hr.
$D$ = outside diameter of the cable in in.
$k$ = a function of $(VD/e)$ where $e$ depends upon the medium, $e$ being 0.000159 for air. For ordinary sizes of conductor $k$ is a constant having a value of 3.26

A graphic solution of eq. 14 is given by Fig. 11. This formula applies to a uniform wind velocity normal to the axis of the wire. Such ideal wind conditions rarely if ever exist over a transmission span, for both velocity and direction have been found to vary widely even in short spans. ("Measurement of Wind Pressures on Overhead Lines," R. H.

## Table III—Vibration Data Pertaining to Records Shown in Fig. 12

| Record No. | Conductor: Cir. Mils or B&S Gage | Conductor: Diameter in In. | Conductor: Span Length, Ft. | Conductor: Tension in Lb | Wind: Velocity Mi. per Hr. | Wind: Angle Deg. | Observed Vibration: Loop Length, Ft. | Observed Vibration: Amplitude in 32nds In. | Observed Vibration: Frequency Cycles per Sec. | Calculated Frequency Cycles per Sec. |

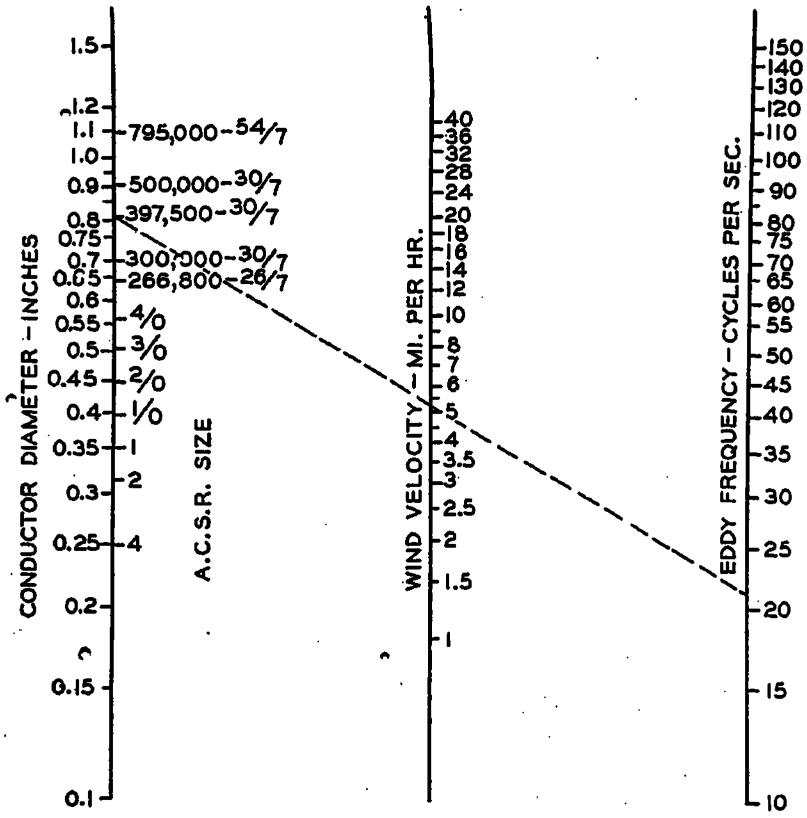

Fig. 11. Graphical solution of Relf and Ower formula for wind eddy frequency of circular cables

Sherlock, N.E.L.A. *Bulletin,* Jan. 1931, p. 29.) ("Characteristics of Wind Gusts," R. H. Sherlock and M. B. Stout, N.E.L.A. *Bulletin,* Jan. 1932, p. 20.) Velocity varies with elevation, and in a long span the height of conductor is not constant; direction shifts rapidly as indicated by any weather vane. The normal component of velocity probably should be used in computing frequency when direction of the wind is oblique. This assumption seems to be in error for small acute angles. A cable has considerable inertia and when once vibrating in any particular mode will not change frequency quickly with slight changes in wind direction or velocity. For these reasons the observed frequency sometimes differs greatly from the theoretical, but with steady wind and obliquity not under 45 deg. the agreement usually is close.

### Field Records of Vibration

Numerous records of frequency and amplitude for conductors of various sizes have been obtained. Fig. 12 shows characteristic vibration records for each of four sizes of A.C.S.R. with pertinent data given in Table III. Agreement between observed and calculated frequencies is fairly close. These records all show recurring beats, possibly caused by variations of wind velocity; with span length and frequency known, the time between recurrences of any particular beat determines velocity of wave propagation, tension, and theoretical loop length.

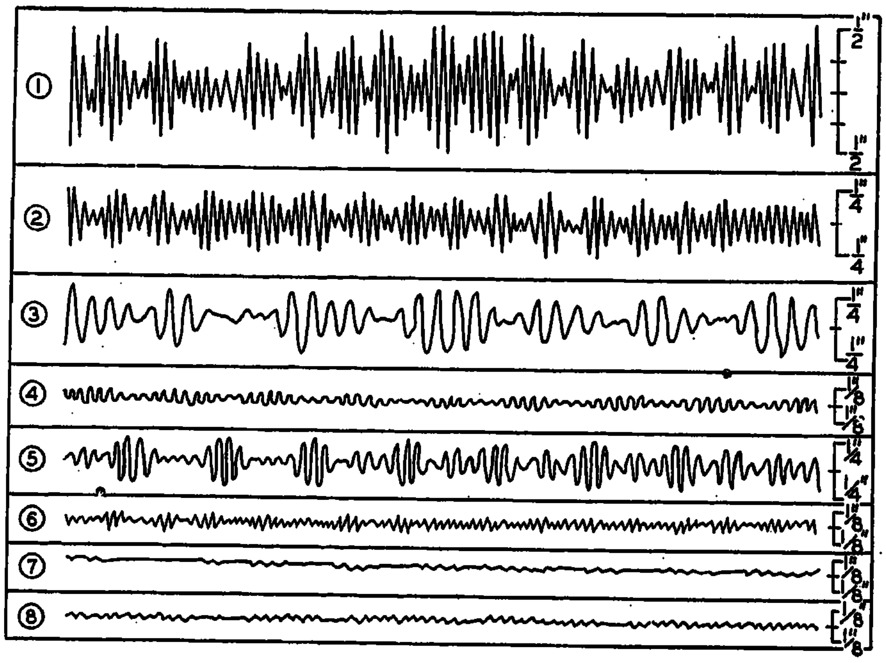

Fig. 12. Vibration records for four sizes of A.C.S.R., see Table III

Observation proves the statement that cables of any material will vibrate when conditions are favorable. One of the earliest instances of damage from vibration was recorded over 20 years ago on the Carquinez Straights Crossing of the Pacific Gas and Electric Company. A few years after installation breakage of strands was discovered in the heavy plough-steel conductors. It is interesting to note that the use of parallel reinforcing or stiffening cables extending some distance out from the support, which was developed here, have been used since on many long river crossing spans.

Records of frequency and amplitude of vibration for conductors made of materials other than A.C.S.R. are shown in Fig. 13; data pertaining to these records are given in Table IV.

### Influence of Tension

Vibration frequency is a function of wind velocity and diameter of conductor and is independent of tension. From eq. 1 it may be seen that for a given frequency the loop length, however, varies directly as the square root of the tension. Therefore, an increase in tension increases loop length and theoretically should render it more difficult for the conductor to fall into resonance with the wind eddy frequency.

Field records to determine the effect of tension were obtained at Royse City; 2 No. 2 A.C.S.R. conductors were erected on a 416-ft. span with tensions of 500 and 750 lb., respectively. Simultaneous 24-hr. records were taken for several weeks, a typical record being shown in Fig. 14; as may be seen, both conductors vibrated for about the same period of time and the amplitude increased slightly with an increase in tension.

Another tension test was made on a 1,160-ft. span of 795,000 cir. mil A.C.S.R. in New Jersey. The tension was 5,400 lb. in one of the parallel conductors and 9,000 lb. in the other, a difference of over 50 per cent. Comparative records were obtained for several weeks during which vibration occurred on a few occasions, but for short periods only. The results were comparable to those obtained at Royse City.

From these tests it appears that vibration will occur at any practical tension when wind conditions are favorable. A reduction of tension decreases the direct stress in the conductor but does not decrease the tendency to vibrate.

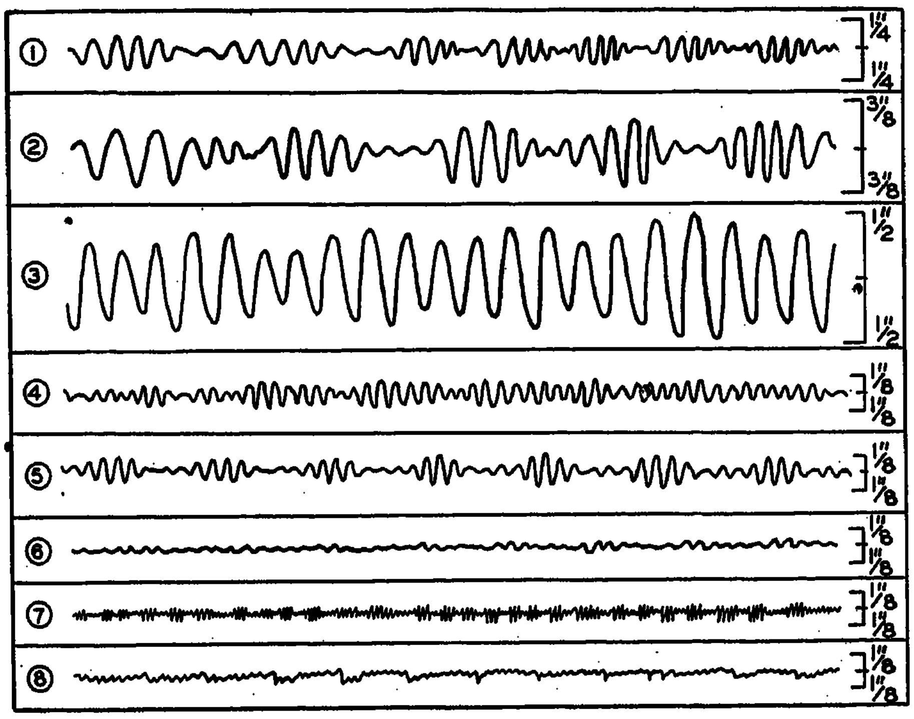

Fig. 13. Vibration records for cables of various materials; see Table IV

## Influence of Conductor Shape

It is obvious that the shape of a conductor should influence its vibration, and field tests prove that it actually does. At Royse City the relatively smooth No. 2 and 397,500 cir. mil A.C.S.R. are observed to vibrate more frequently than the 4/0 which has a comparatively rough exterior due to larger strands.

A special test to show influence of shape was made with three No. 2 all aluminum conductors, 1 a single wire, 1 of 3 strands, and 1 of 7 strands. Over a

| 1 | 650,000 cir. mils copper calson bronze core | 1.13 | 835 | 9,500 | 4.5 | 90 | 11.5 | 12 | 16 | 14 |
| 2 | | 1.13 | 835 | 9,500 | 2 | 85 | 17.7 | 19 | 10 | 9 |
| 3 | 400,000 cir. mils 19 str. copper | 0.728 | 1,200 | 5,100 | 4 | 70 | | 32 | 21 | 18 |
| 4 | 250,000 cir. mils 19 str. copper | 0.575 | 1,125 | 5,550 | 5.75 | 66 | 8 | 9 | 29 | 30 |
| 5 | 250,000 cir. mils 19 str. copper | 0.575 | 1,125 | 5,550 | 6 | 66 | 8 | 9 | 25 | 31 |
| 6 | 4/0 copper | 0.528 | 750 | 3,200 | 6.8 | 80 | 6.9 | 6 | 25 | 29 |
| 7 | 3/8 in. steel | 0.375 | 650 | 3,800 | 8.75 | 90 | 3.75 | 4 | 88 | 89 |
| 8 | 3/8 in. steel | 0.375 | 650 | 3,800 | 10 | 75 | 3 | 3 | 99 | 102 |

period of several weeks 24-hr. vibration charts were obtained for several tensions. The recorders being set the same distance from the supports, and the tensions being the same, the amplitudes are comparable. Typical charts are shown in Fig. 15; these indicate that the 3-strand cable vibrated least frequently and with the smallest amplitude, the 7-strand was second, and the solid wire vibrated the most. In no case was vibration absent.

Another test was conducted on a special eccentric A.C.S.R. (418,000 cir. mils of aluminum); the outer layer of strands in this cable, being graduated in size, formed an enlargement which wound helically around the conductor axis. This cable was installed on a span of 1,125 ft. parallel to a standard 397,500 cir. mil A.C.S.R. of approximately the same diameter and proportion of steel. A record showing comparative vibration of the 2 cables is shown in Fig. 16.

These experiments show that amplitude can be reduced by variation in shape but that it is doubtful if a practical vibrationless conductor can be obtained in this manner.

## Energy Transmitted to Supports

Severe conductor vibration sometimes causes supporting structural members to vibrate noticeably, and fatigue failures at bolt holes in small alloy steel crossarm members have been reported. To measure the variation in vertical load transmitted to the structure a small steel rod of high elastic limit was inserted between the suspension clamp and the insulator string on a 1,125-foot span of 795,000 cir. mil A.C.S.R. An accurate load-deformation curve for this rod had previously been determined with a Huggenberger tensometer. Several readings made under varying conditions of vibration showed that the variation in vertical load was of the order of 100 to 150 lb.

**Table V—Vibration Data Pertaining to Records of Fig. 17**

|  | A.C.S.R. Conductors |  |  |  | Recorder |
|---|---|---|---|---|---|
| Record No. | Size in Cir. Mils or B & S Gage | Diameter in In. | Span Length, Ft. | Tension in Lb. @ 60° F. | Distance from Support |
| 1 | 795,000 | 1.093 | 1,125 | 6,755 | 5 ft. 2 in. |
| 2 | 795,000 | 1.093 | 1,125 | 6,810 | 5 ft. 0 in. |

**Fig. 16. Vibration records showing effect of eccentric conductor cross-section**

## Moving Pictures of Vibrating Cable

An ordinary moving picture camera taking 16 exposures per second is too slow to show vibration at a frequency of 25 cycles or more; a high-speed camera, however, taking 128 exposures per second "slows down" the vibration so that the motion of the cable can be followed readily on the screen. One reel was taken of a 795,000-cir. mil A.C.S.R. while the wind velocity was high and the cable vibrating with short loop length, high frequency, and small amplitude. A second reel was taken while the wind velocity was low with correspondingly lower frequency, longer loop length, and greater amplitude. Rocking of the suspension clamp is clearly shown and beat pulsations are evident.

## Effect of Dampers

The problem of damping a vibrating conductor differs from many damping problems in that the damper must be effective over a wide range of frequencies. This precludes the use of a tuned dynamic vibration absorber for which the theory was presented by J. Ormondroyd and J. P. DenHartog ("The Dynamic Vibration Absorber," *Trans.*

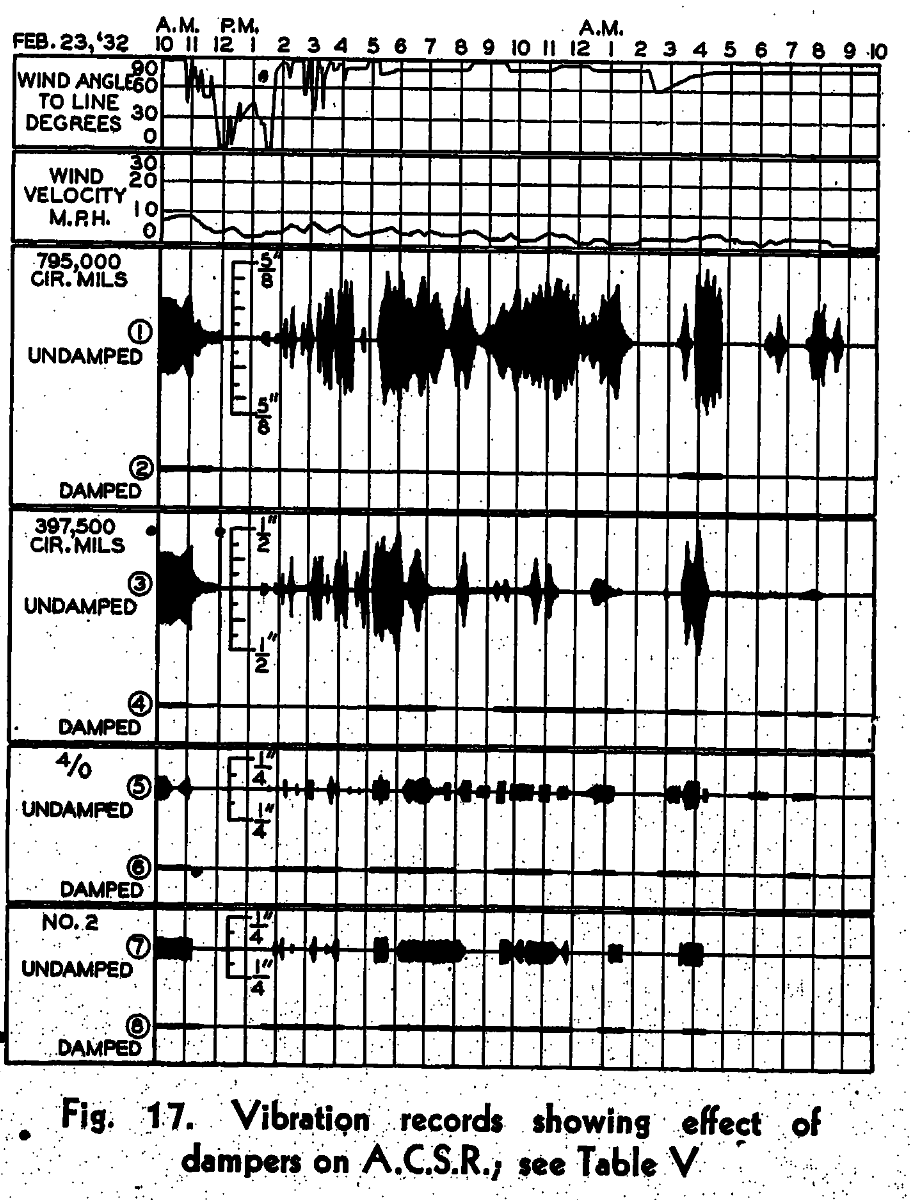

**Fig. 17. Vibration records showing effect of dampers on A.C.S.R., see Table V**

## Table VI—Vibration Data Pertaining to Records Shown in Fig. 18

| | Conductor | | | | Wind | | Observed Vibration | | | |
|---|---|---|---|---|---|---|---|---|---|---|
| Record No. | Size and Material | Diameter in In. | Span Length, Ft. | Tension in Lb. | Velocity Mi. per Hr. | Angle Deg. | Loop Length, Ft. | Amplitude in 32nds In. | Frequency Cycles per Sec. | Calculated Frequency Cycles per Sec. |
| 1 | 4/0 A.C.S.R. | 0.563 | 550 | 2,630 | 3 | 75 | 11.95 | 6 | 23 | 22 |
| 2 | 4/0 A.C.S.R. | 0.563 | 550 | 2,630 | 3 | 75 | | | | |
| 3 | 4/0 A.C.S.R. | 0.563 | 550 | 2,650 | 4 | 75 | 11.7 | 8 | 23 | 22 |
| 4 | 4/0 A.C.S.R. | 0.563 | 550 | 2,650 | 4 | 75 | | | | |

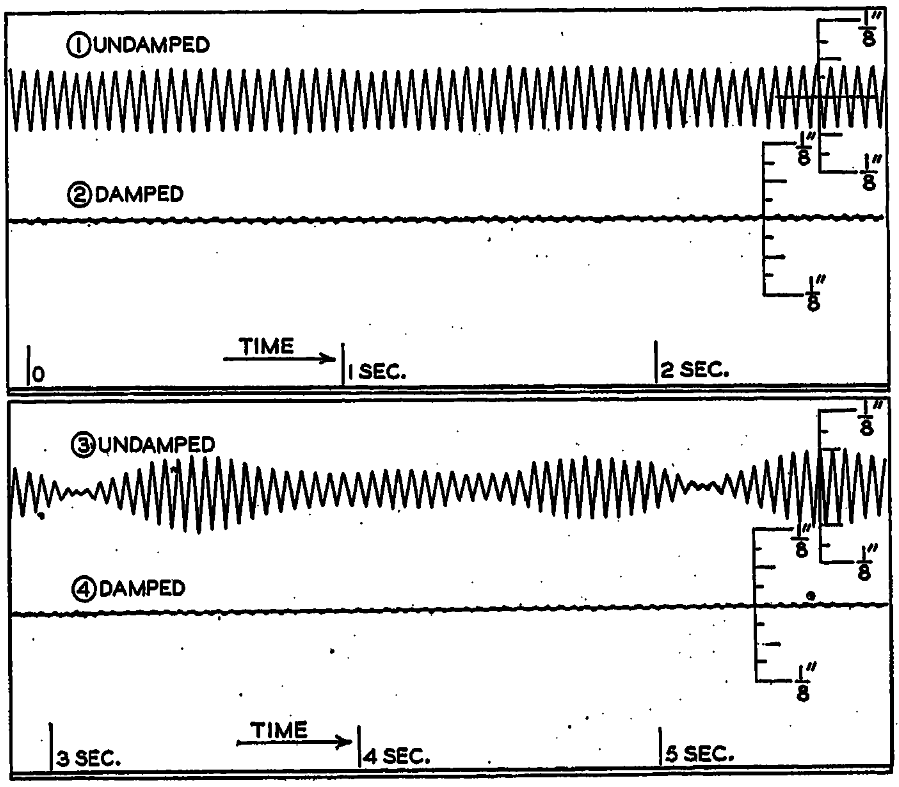

Fig. 18. Oscillographic vibration records showing effect of dampers on 4/0 A.C.S.R., Caldwell-Ontario (Idaho Power Company) 132-kv. line; see Table VI

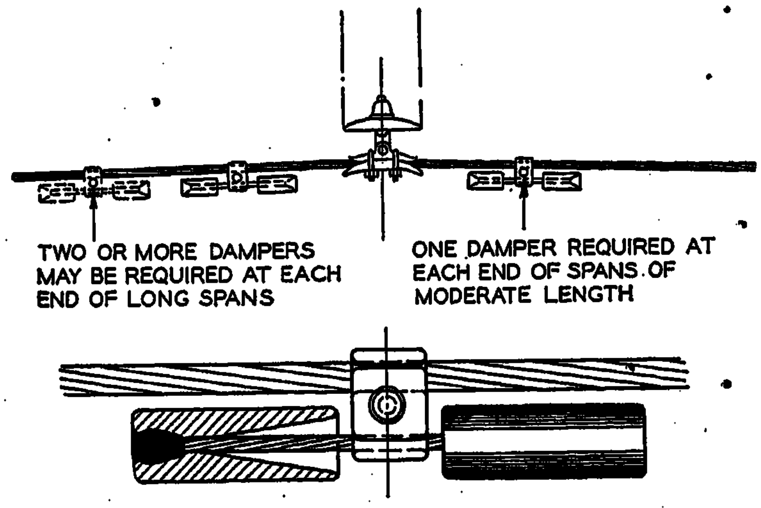
A.S.M.E., 1928). Such an absorber theoretically consumes no energy; hence it seems that it cannot damp vibration where there is a continuing input of energy as on a transmission line. The dynamic absorber with damping is effective over a broad band of frequencies and also consumes energy. The theoretical formulas of the Ormondroyd-DenHartog paper for this type of damper are applicable to a vibrating cable in principle only and require extensive modification and laboratory determination of certain constants.

It is of interest to note that a simple weight of suitable size at the center of one loop of a vibrating cable is somewhat effective as a damper. The added weight alters the natural period of that one loop and, with the forced vibration which then ensues in that particular loop, the vibration is damped by consumption of energy in the conductor itself in that loop. The practical difficulty is, however, that a node is soon established at the weight and vibration is renewed.

Energy which must be consumed to damp vibration is undoubtedly extremely small in amount. This is evident from the theoretical formula developed by Bate ("The Vibration of Transmission Conductors," *Trans.* Inst. Engrs., Australia, 1930, p. 277) for the input of energy to a cable from wind eddies. His formula involves several assumptions which have not been proved but the method of derivation is logical and dimensionally it is probably correct. The formula gives the energy input per loop per cycle, $G$ in ft.-lb., as follows:



TWO OR MORE DAMPERS MAY BE REQUIRED AT EACH END OF LONG SPANS
ONE DAMPER REQUIRED AT EACH END OF SPANS OF MODERATE LENGTH

Fig. 19. Stockbridge damper assembly

$$G = 0.000022\ V^2DAL' \qquad (15)$$

where

$V$ = velocity of wind in mi. per hr.
$D$ = outside diameter of the cable in in.
$A$ = amplitude of vibration in in.
$L'$ = loop length or distance between node points in ft.

This formula shows that the input of energy is proportional to the amplitude; hence if amplitude can be restrained to a small value the energy input will be small. This agrees with the observed fact that vibration builds up slowly and is damped easily at first.

One reason for establishing the outdoor laboratory was to study the action of dampers. The usual method of observation is by comparison of 24-hr. vibration records from 2 conductors identical in size, span length, and tension, 1 damped and 1 undamped. Many different dampers have been tested at Royse City, and hundreds of comparative records have been obtained.

The most successful damper tested is essentially a mass resiliently attached to the conductor in the loop nearest the support and so designed that energy is consumed by friction or mechanical hysteresis. This damper was developed by G. H. Stockbridge of the Southern California Edison Company. The usual form consists of 2 weights connected by a short piece of stranded steel cable, this assembly being attached to the conductor a short distance out from the insulator. This damper is simple and practical to construct and easy to install, even on hot lines. The weight, size, and length of stranded cable, and location in the span vary for different diameters of conductor. For spans of moderate length, say under 1,000 ft., 1 damper at each end of the span is required.

Comparative 24-hr. vibration records are shown in Fig. 17 with supplementary data in Table V, for a damped and an undamped span of 4 sizes of A.C.S.R. at Royse City, including wind direction and velocity recorded at one end of the span. It is evident that the dampers suppressed practically all visible vibration; also that the energy input from the wind is directly proportional to the length of the span. In long spans better damping is obtained with 2 dampers at each end, while 3 or more may be required on extremely long spans.

A damper cannot act effectively until the conductor vibration acquires a certain amplitude. This is manifested by a slight quiver which can be felt but barely seen. The 24-hr. charts, however, do not show this clearly. Recently a series of records from a free and a damped span of 4/0 A.C.S.R. was obtained by engineers of the Idaho Power Company using a carbon pile oscillograph; Fig. 18 shows 2 of their oscillograph records. The ripple in the damped cable is scarcely visible even at the enlarged scale.

Many tests on Stockbridge dampers have been made to determine the best dimensions and point of attachment to the conductor. The dampers are not critical either as regards size or spacing—a variation of 25 per cent in any factor will not seriously affect performance. Fig. 19 shows the style of Stockbridge damper used in this investigation. To avoid corona discharge this design embodies cylindrical weights which shield the damper cable, and a clamp having no sharp corners.

## ARMOR RODS

Armor rods are primarily reinforcement but they also are effective as dampers. Numerous comparative records have indicated that they reduce vibration amplitude by 10 to 20 per cent. Armor rods reduce stresses by distributing the bending from vibration, reinforce the cable at the point where the stresses are greatest, and furnish valuable protection against flashover burns.

## CONCLUSIONS

Principal findings of the field tests described in this article may be summarized as follows:

1. Theoretical formulas (*loc. cit.*) expressing relationship between frequency, loop length, tension, and weight of a vibrating conductor are in good agreement with field observations.
2. The Relf and Ower formula (*loc. cit.*) for the frequency of a vibrating cable is substantially correct.
3. Any suspended cable will vibrate when conditions are favorable.
4. Any feasible reduction in tension will not prevent vibration.
5. Modifications in shape of cable cross section and stranding have some beneficial effect in reducing amplitude, but the results do not support the idea that a vibrationless cable can be evolved.
6. Variation in vertical load transmitted to the insulator is not large.
7. Slow-motion moving pictures of vibrating cable enable the motion to be followed by eye but have been of little assistance.
8. A properly designed damper will prevent vibration of any appreciable amplitude, and since the input of energy from the wind varies directly as the amplitude an effective damper is required to absorb but little energy.
9. The Stockbridge damper gives best results, is simple in design and construction, has no moving parts, and is easy to install.
10. Armor rods are primarily reinforcement although they reduce the amplitude of vibration by 10 to 20 per cent.
11. Adequate practical protection against damage from vibration of conductors is afforded by proper use of armor rods or dampers.

# Engineering Subjects in the College Program

**For each of a large number of technical institutions, the various electrical and related subjects in the 4-year college program of electrical engineering have been subjected to an analysis. The results of this study are presented herewith, with suggestions for improvement in existing curricula.**

By
ALFRED H. LOVELL
MEMBER A.I.E.E.
Univ. of Michigan,
Ann Arbor, Mich.

IN THE FIELD of education for electrical engineering both the teacher and the practising engineer are vitally concerned; the teacher, because it is his life work, the practitioner because the young graduates are presumably trained to meet the specifications of his profession, to join its ranks, and to work beside him in the years to come. Obviously the working relations of man to man and the characteristics of the profession will be determined more or less by the nature of the training given the young men who come into it at the rate of approximately 3,000 a year. In this sphere 2 great national organizations, the Society for the Promotion of Engineering Education and the American Institute of Electrical Engineers, have mutual interests and interlocking membership. It would seem well to set aside for the special consideration of the S.P.E.E., the methods of selection, the study of teaching methods, the operating details, and organization of curricula; but certainly then, it is the special function of the A.I.E.E. to advise as to the economic and professional content and interrelations of programs.

---

Full text of "Engineering Subjects, Electrical and Cognate, in the Four-Year College Program of Electrical Engineering" (No. 32-74) presented at the A.I.E.E. summer convention, Cleveland, Ohio, June 20–24, 1932.

As a matter of background, the study of engineering education by the S.P.E.E., 1923–1929, brought out a synthesis of opinion from teachers and engineers as to what engineering curricula should be. This, presented in "Report of the Investigation of Engineering Education," v. 1, p. 413, is as follows:

1. Moderate diversity but tending away from specialization.
2. Dominance of the scientific and broadly technical content and emphasis.
3. Inclusion of a well-identified core of required subject matter.
4. Inclusion, at all stages, of subjects of purely cultural value.
5. Due emphasis (though not predominant) on the economic aspects of engineering and on their bearing on administration and management.
6. Coherence of arrangement and coordination of related subjects.
7. Thoroughness rather than completeness of detail.

It will be remembered with regard to "specialization" that instead of the general sense of the word as applied to the differentiation of instruction in accordance with the major divisions of engineering—civil, electrical, mechanical, etc., the S.P.E.E. used the term in the above discussion in a narrower sense as applied to a further degree of differentiation of curricula within the major fields themselves, such, for example, as the provision of distinct curricula in sanitary engineering, structural engineering, and the like, within the major field of civil engineering. There was common agreement between the teachers and engineers that the primary purpose of instruction in specialized engineering subjects should be to teach fundamental principles and methods rather than to train for particular kinds of work. The engineers emphasized the opinion that specialization is out of place in undergraduate curricula and that thorough grounding in fundamentals is of paramount importance. Yet many of the teachers believed that in teaching specialized engineering subjects there is no essential conflict between preparation for particular fields of work and training in fundamental principles and methods, although the latter should always be the primary purpose. It has been a standard educational policy that principles are best taught in connection with their applications, and that the technical subjects proper should serve as media for teaching principles and the characteristic engineering methods of thought and analysis, instead of attempting preparation for specific types of practise.

**Table I—Semester Hours Average Requirements for Graduation in Electrical Engineering**

| S.P.E.E. Report, 1923–1929 Subject Group | Units | S.P.E.E. Report, 1930 Subjects | Units |
|---|---|---|---|
| Electrical Engineering | 34.4 | Technological Subjects<br>Major Branch | 39.0 |
| Other Engineering | 42.1 | Other Technical Subjects | 23.5 |
| Engineering Electives | 6.8 | Electives | 10.4 |
| Non-Engineering Electives | 1.8 | Shop | 4.6 |
| Miscellaneous | 0.1 | Drawing | 7.2 |
| Phys. and Mil. Training | 6.6 | Phys. and Mil. Education | 4.6 |
| Foreign Language | 2.1 | Modern Foreign Language | 1.2 |
| Social Science | 4.4 | Economics | 4.7 |
| Physical Science | 20.6 | Physical Science | 20.7 |
| English | 8.9 | English | 9.0 |
| Mathematics | 18.9 | Mathematics | 18.5 |
| Total Non-Engineering | 63.6 | | |
| Total Engineering | 83.3 | | |
| Total Prescribed | 137.6 | Total Prescribed | 133.0 |
| Total Elective | 9.3 | Total Elective | 10.4 |
| Grand Total | 146.9 | Grand Total | 143.4 |
| Number of Institutions | 55 | Number of Institutions | 51 |

The engineers were strongly in favor of extended training in economics and for a greater emphasis upon the economic phases in the engineering subjects proper. A large majority of the teachers, engineers, and graduates who were questioned indicated the belief that foreign languages as taught at that time were not of sufficient value to warrant their inclusion as requirements in the engineering curriculum. Both teachers and engineers were in agreement that shop work should not be required of all students, but only of those enrolled in curricula most closely related to the manufacturing industries. As a result of these definite criticisms and recommendations, chiefly with regard to the preparatory and secondary courses in the curricula, many of the colleges have changed their requirements to meet the recommendations. The progress in this respect may be estimated by comparing the 2 columns in Table I. Unfortunately, the 2 tabulations were not made in exactly the same subdivisions, but "Shop and Drawing" listed as items in the 1930 report are evidently included in the "Other Engineering" item of the 1923–1929 report, while "Engineering Electives," "Non-Engineering Electives" and "Miscellaneous" of the 1923–1929 report are doubtless all combined into the item of "Electives" in the 1930 report. The other subjects, however, listed side by side, appear to agree exactly.

The slight increase in English and economics with the corresponding decrease in modern foreign languages is notable. Still this does not show the full effect of the change, since some colleges still are revising their curricula in this respect. For example, the college of engineering at the University of Michigan will change its requirements as of September 1932, dropping 16 hours of foreign language or non-technical electives in favor of 4 additional hours required in English, 6 hours required in economics, and 6 hours of free non-technical electives.

It is believed, then, that a great improvement has been made in the preparatory and secondary parts of the curriculum in electrical engineering as a result of the foregoing study and discussion. Some glaring omissions have been remedied and some old ideas have given way to new and present conditions. The fact that the recommendations after careful analysis by the colleges have been so widely adopted shows how valuable the recommendations of the practising engineers have been, and how much they have achieved. We should expect, therefore, similar advantages to accrue from a study and discussion of the technical portion of our curriculum in something like the detail which was thus given to the preparatory and secondary subjects.

## TECHNOLOGICAL SUBJECTS

With regard to the technological portion of the curriculum in electrical engineering the tabulations of the total semester hours allotted to these subjects in the major branch of electrical engineering itself, those in other engineering fields and those in engineering electives, in the 1923–1929 and 1930 S.P.E.E. reports, are given in Table II.

It is noted that while there has been an increase in the central core of subjects in electrical engineering itself from 34.4 to 39.0, still the electrical curriculum contains fewer technical courses in its own field than any of the other major curricula, particularly those of chemical and civil engineering with their respective requirements of 44.9 and 50 semester hours in their own major branch. It would appear, then, that the electrical engineering students take proportionately more of their technical work in associated departments and in electives, a situation which will heartily commend itself from the points of view of broad foundational training and freedom for the student to pursue his ambitions to at least a slight degree into some particular field of his own choice.

The tendency to increase the number of semester hours of technical requirements in electrical engineering was noted in the 1923–1929 S.P.E.E. report. That it prevailed and resulted in an 11 per cent increase is shown by the report for 1930. In view of the close approach to an upper limit, should we not examine how scientific the training of a 4-year electrical student should be? Doubtless we are all agreed that he must have as an absolute minimum, say, some 16 semester hours of fundamentals in d-c. and a-c. machinery and steady-state circuits. But in the light of modern developments and in preparation for some known problems of the future, how much further should we go?

The electrical engineers who were consulted in 1923–1929 as to which divisions of electrical engineering were of such importance as to warrant their inclusion in the training of all electrical students replied as shown in Table III. (It was taken for granted that a general foundation in the principles of electrical and magnetic units, laws, circuits, and machines would be required of course in every case.) In view of the developments of the past few years and of immediate future demands, surely the subject of electronics and vacuum tubes should be added to the list. Such a course should include an engineering approach to the theories of ionization, of the mechanisms of current flow and energy interchanges in ionized regions, and of thermionic, photoelectric, and other types of electron emission, as related to conducting gases at atmospheric and lower pressures. The study should cover thermionic vacuum tube characteristics and types of circuits and tubes suitable for rectifiers, amplifiers, detectors, and oscillators.

**Table II—Semester Hours Required for Graduation in Different Courses**

| 1923–1929 | | 1930 | | | | |
|---|---|---|---|---|---|---|
| Subjects | Units | Subjects | E.E. | M.E. | C.E. | Ch.E. |

ANALYSIS OF COLLEGE CURRICULA

Not all of the subjects in Table III are standard requirements in college curricula but nearly all are represented in the programs as requirements or available electives, the exception being perhaps electrochemical engineering which in practically every case is offered in the departments of chemistry. The study summarized in Table IV shows what a number of representative schools provide in required and elective courses in these subjects.

It is notable that there is great consistency in the first 4 columns of Table IV in that nearly all colleges require a group of fundamental courses of not less than 16 hours and also provide 1 or 2 courses in transmission and distribution, power plants, and electrical machine design. The few schools whose catalogs do not show a course in electrical power plants provide a strong preparation in the courses they schedule in the heat power division of mechanical engineering. There is also strong agreement in using the field of power plant engineering as the vehicle for applying economics to engineering problems. In the remaining columns for the electrical division of Table IV the courses offered are mainly elective, the restriction of time allowing the undergraduate student probably not more than 1, or at most 2, courses in any division. Many colleges offer several sequential electives in the various divisions, but the courses are principally for graduate students. There are difficulties in analyzing the curricula in these divisions. Illumination may be offered in some cases in the department of physics; telephony, telegraphy, radio, and electronics, may be combined in various ways in courses given as communication engineering.

**Table III—Per Cent of Engineers Favoring Inclusion of Various Subjects**

| Per Cent | Subjects | Per Cent | Subjects |
|---|---|---|---|
| 67.5 | Transmission and distribution | 33.5 | Illumination |
| 59.0 | Power plant engineering | 33.2 | Electrochemical engineering |
| 57.0 | Electric machine design | 28.4 | Electric railways |
| 44.0 | Industrial power engineering | 22.5 | Telephony-telegraphy |
| 38.8 | Hydroelectric engineering | 19.5 | Radio engineering |

RELATED ENGINEERING SUBJECTS

In order that the preparation shall have a proper breadth, and that the graduate shall understand something of the problems facing his colleagues, what should be the training of electrical students in the fields of the associated technical departments of mechanical, chemical, and civil engineering?

In mechanical engineering the electrical student has need of a fundamental course dealing in elementary thermodynamics, steam, fuels, boilers, steam

engines and turbines, condensers, internal combustion engines, and the general problem of a power plant. Some time in steam laboratory would be valuable to vitalize the work. It will be necessary to establish the standard ratings, efficiencies, methods of governing, and speed regulation of the prime movers here so that they may be transferred to the electrical courses concerned with the generator.

To chemical engineering we look for a knowledge of the engineering materials with which to work. For general structural and power work every student needs an elementary knowledge of the manufacture and properties of the ferrous and non-ferrous alloys, cements, clay products, protective coatings, fuels, boiler scale, and water softening, together with associated laboratory experience in mechanical working and heat treatment of the various metals, welding practise, protection against corrosion, etc. In addition to these widely used materials which are generally covered in the common introductory course in chemical engineering, the electrical student has a special interest in the silicon steels, in oils and papers, in cold and hot flow materials, in phenol plastics, varnishes, tapes, and mica. Seemingly no course given at the present time covers these materials which are so essential to the electrical designer. They should be included in the more comprehensive list of fundamental materials for an electrical student.

In civil engineering a common basic structural design course may follow some 8 semester hours of engineering mechanics, or the same field may be covered as applied mechanics in the last named department. At the University of Michigan the preparatory design courses in mechanics cover statics, 3 hours; strength and elasticity of materials, 4 hours; laboratory in strength of materials, 1 hour; and dynamics, 3 hours. In a fundamental structural design course we feel that the student should have some elementary training in analysis of stresses, moments and shear, for wood, steel and concrete beams, roof trusses and columns; beams and slabs in reinforced concrete masonry; and introduction to soil bearing theory, bearing power of piling, and settlement, together with some contact with electric welding of frames and machine structures.

For curricula in electrical engineering, the semester hours required in cognate or related engineering subjects are shown in the right hand side of Table IV. While there is almost general agreement as to the necessity for courses in heat power, shop work, and hydraulics, there is evidently a considerable difference of opinion as to the need for training in surveying and in the mechanical features of machine design. Again, almost half of the programs offer no training in engineering materials and only 3 curricula call for a structural design course after a preparation in engineering mechanics.

In view of these differences of opinion among teachers not only as to the subjects to be included in the fundamental training of the student but as to the time spent upon them as well, it is felt that consideration and study and the gathering of suggestions from the practising members of our profession would be very much worth while.

# Control for 3,000-Volt Multiple Unit Cars

**Because of the relatively high voltage used and the necessity of mounting the apparatus in a limited space, many new problems of control design were encountered in the 3,000-volt d-c. suburban electrification of the Lackawanna Railroad. This article describes the construction and operation of some of the more important of the control apparatus developed, and the tests made to assure its suitability to the service for which it was designed.**

By
C. J. AXTELL
MEMBER A.I.E.E.

General Elec. Co., Erie, Pa.

THE 282 CARS on the Delaware, Lackawanna and Western suburban electrified system are arranged to operate as 141 units, each unit consisting of 1 motor car and 1 trail car semi-permanently connected; each motor car has 4 1,500/3,000-volt motors of 235 hp. hourly rating, 2 motors being permanently connected in series. Operating stations are provided at each end of each 2-car unit, 1 on the motor car and 1 on the trail car. Trains are made up of from 1 unit (2 cars) to 6 units (12 cars). The auxiliary control of these cars has been described previously ("Auxiliaries for High Voltage D-C. Multiple Unit Cars," by C. J. Axtell, A.I.E.E. TRANS., v. 49, 1930, p. 1282–6); hence this article will treat only features of the control for the traction motors.

Motor control is of the pneumatically operated cam type with automatic acceleration at the rate of 1.5 miles per hr. per sec. The following control points or steps are provided:

6 accelerating steps with 4 motors in series.
1 running step with 4 motors in series.
5 accelerating steps with 4 motors in series-parallel.
1 running step with 4 motors in series-parallel, full field.
1 running step with 4 motors in series-parallel, shunted field.

The control equipment normally operates with a constant air pressure of 70 lb. but will function satisfactorily at a minimum pressure of 50 lb.

A schematic wiring diagram of this motor and control circuit is shown in Fig. 1. A motor generator set and a 300-ampere-hr. battery furnish power at 32 volts for control, lights, and auxiliary circuits; the control equipment is designed, however, to operate over a range of from 20 to 45 volts. Table I gives a listing and weights of the major parts of the control equipment.

**Table I—Weight of Control Equipment of Lackawanna 3,000-Volt Multiple Unit Cars**

| Equipment | Weight in Lb. |
|---|---|
| 2 pantographs | 2,270 |
| 8 pantograph insulators | 340 |
| 1 main fuse in box | 151 |
| 1 main switch and auxiliary fuse box | 313 |
| 1 line breaker | 583 |
| 1 motor controller | 1,119 |
| 1 set motor resistors | 455 |
| 1 field control switch | 88 |
| 2 inductive field shunts | 1,340 |
| 1 master controller | 75 |
| Total weight of motor car control including dynamotor and field shunts | 11,950 |
| Trail car control equipment | 1,260 |
| Total weight of control for 2-car unit | 13,210 |

## CURRENT COLLECTORS

Current for each unit is collected from the double or twin contact wire by a pantograph trolley on each motor car. Pantographs are of the spring-raised air-lowered type, with:

| | |
|---|---|
| 1. Maximum working range | 10 ft. 6 in. |
| 2. Length of contact surface | 4 ft. 0 in. |
| 3. Vertical movement of collector shoe | 2 in |

Bearings on the main shaft are taper roller self-aligning, with pressure lubrication. Contact pressure of the shoes against the wire can be adjusted from 20 to 35 lb. with a maximum difference of 6 lb. between the pressure exerted with the pantograph going up and that exerted with trolley retracting.

## MAIN FUSE

All wiring and apparatus on the car, except the trolleys, is protected by a compression type main fuse mounted on the car roof (see Fig. 2). The fuse holder has two expansion chambers joined by an insulating tube; the fuse consists of 2 braided copper leads with a connecting link of fusible alloy. The vaporizing of the fusible link creates pressure within the tube; this expels the braided copper leads from the tube and extinguishes the arc quickly, without any noise or flame that can be detected.

Arc rupturing tests were made on this fuse with both inductive loads and short circuits on a 3,000-volt 3,000-kw. motor-generator set built especially for high current testing. From oscillograph tests the times required to extinguish the arc completely after the fuse had melted were as follows:

| Volts | Amperes | Circuit | Time (Sec.) |
|---|---|---|---|
| 3,000 | 3,040 | Inductive | 0.030 |
| 3,000 | 7,000 | Non-inductive | 0.0076 |

The oscillograph record of the first test is shown in Fig. 3.

---

Written especially for ELECTRICAL ENGINEERING. *Not published in pamphlet form.*

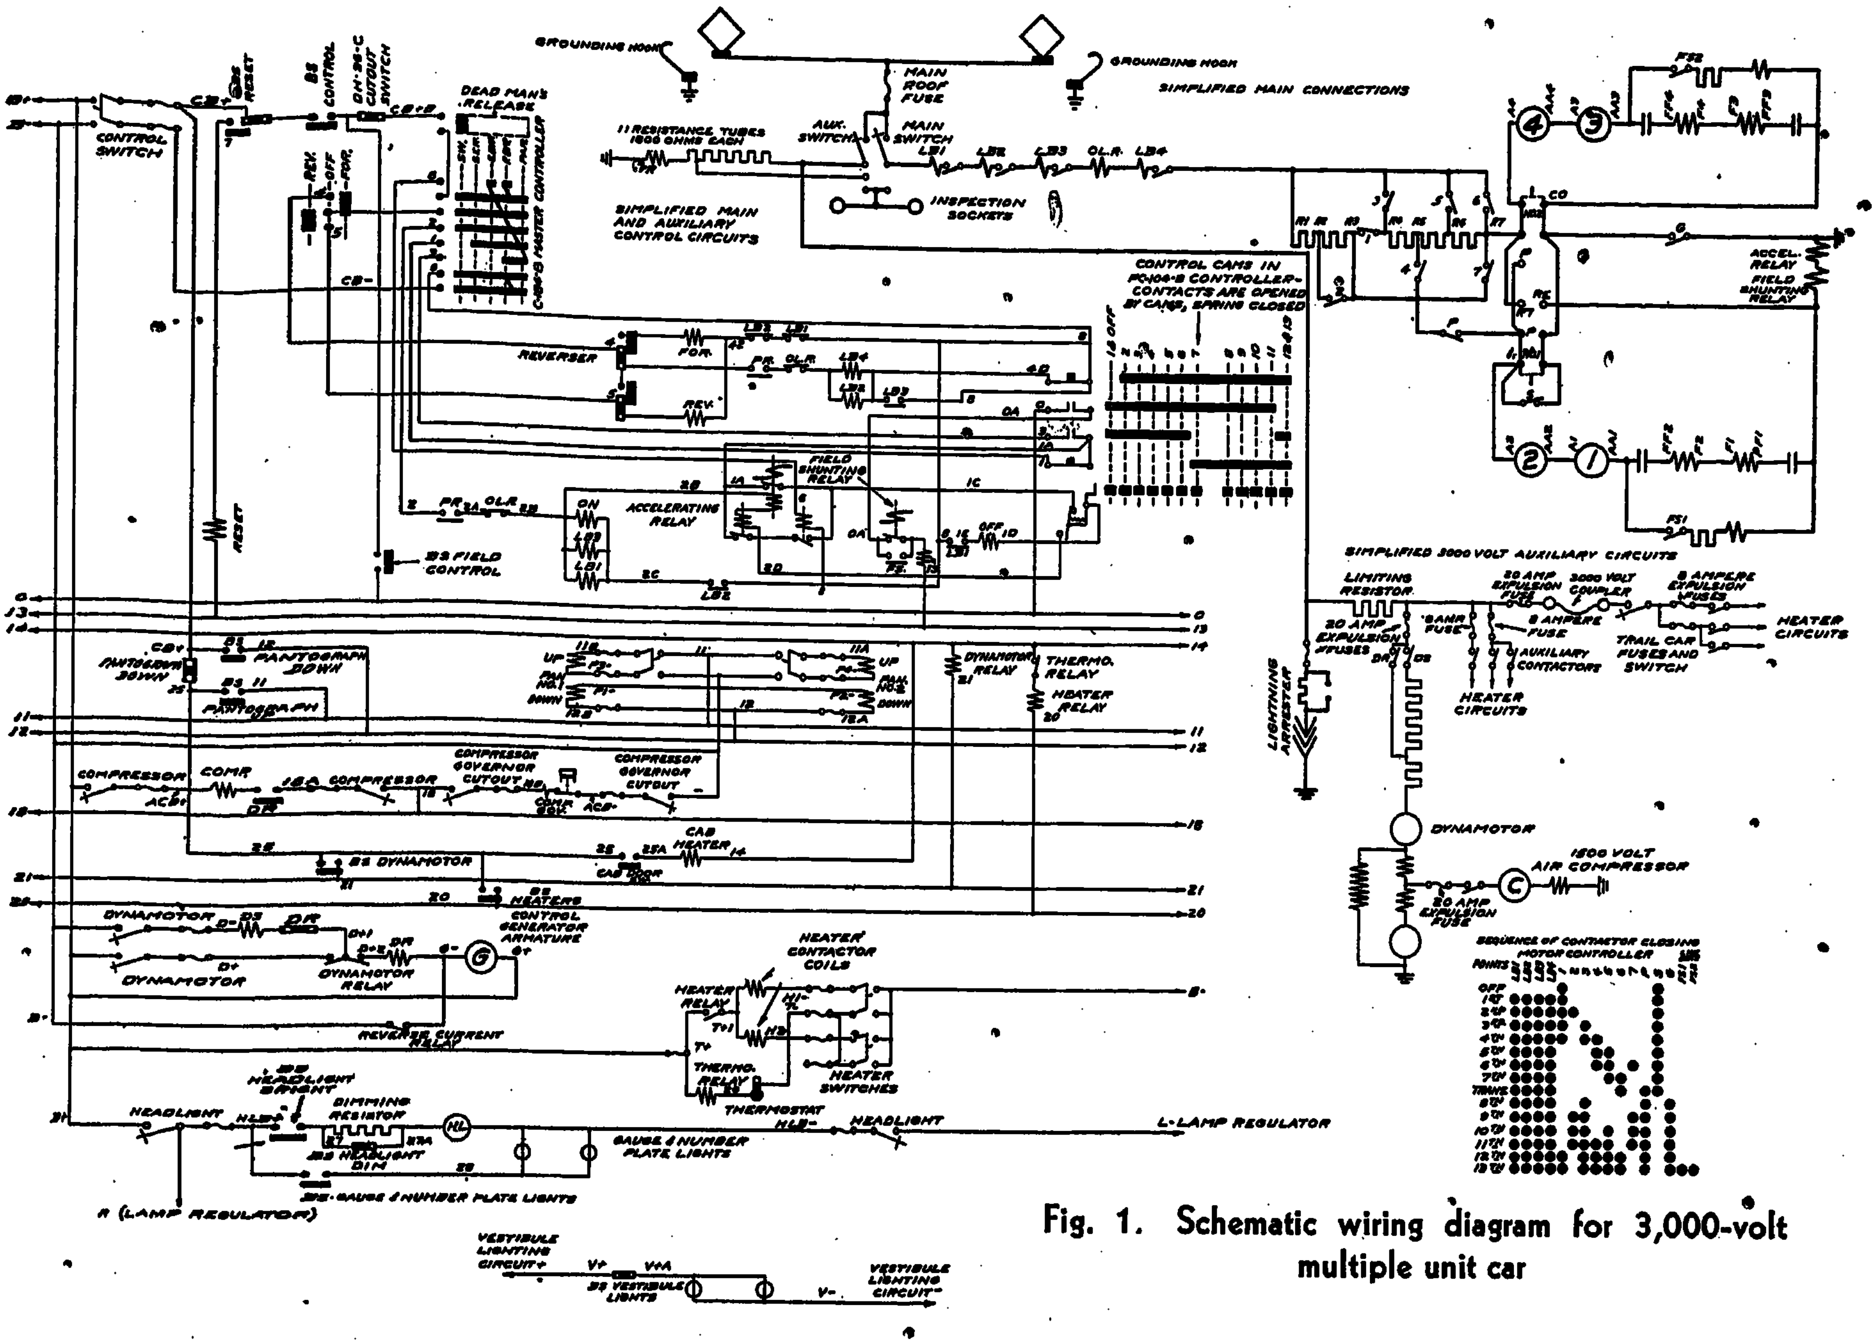

Fig. 1. Schematic wiring diagram for 3,000-volt multiple unit car

## LINE BREAKERS

On these equipments the line breaker is the only device that cuts off the power to the motors; consequently 4 3,000-volt contactors are used in series to rupture normal as well as overload currents. From the standpoint of safety it is essential to have 2 circuit rupturing devices controlled from individual train wires, each device capable of opening the motor circuit; consequently 4 contactors connected in series are used although 2 will interrupt any overload current. The contactors have a nominal capacity of 350 amperes with the blowout coil decreased to 200-ampere capacity to increase the number of turns; the units have $^3/_4$-in. wide tips and a tip gap of 1 in. The contact tip pressure is 70 lb. An overload relay is mounted directly on the back of the No. 4 contactor as shown in Fig. 4.

Oscillograph records made when testing the current rupturing capacity of this breaker show the following times to rupture the circuit after the contact tips begin to part:

| Test No. | Contactors Breaking Circuit | Volts | Amperes | Load | Time Sec. |
|---|---|---|---|---|---|
| 1 | 2 | 3,000 | 4,500 | Non-inductive | 0.017 |
| 2 | 2 | 3,000 | 700 | Inductive | 0.025 |
| 3 | 4 | 3,000 | 1,500 | Inductive | 0.043 |
| 4 | 2 | 3,000 | 1,500 | Inductive | 0.074 |

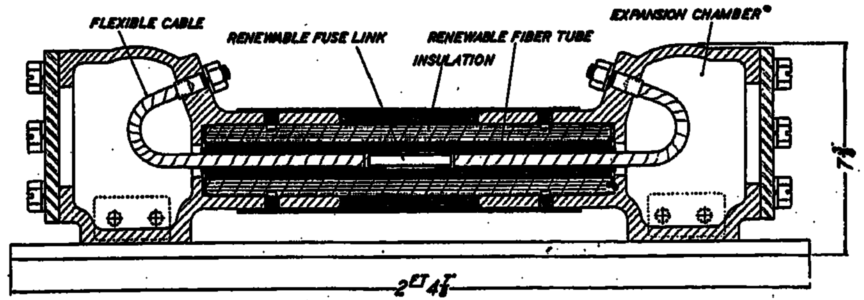

Fig. 2. Cross-section of 3,000-volt main fuse

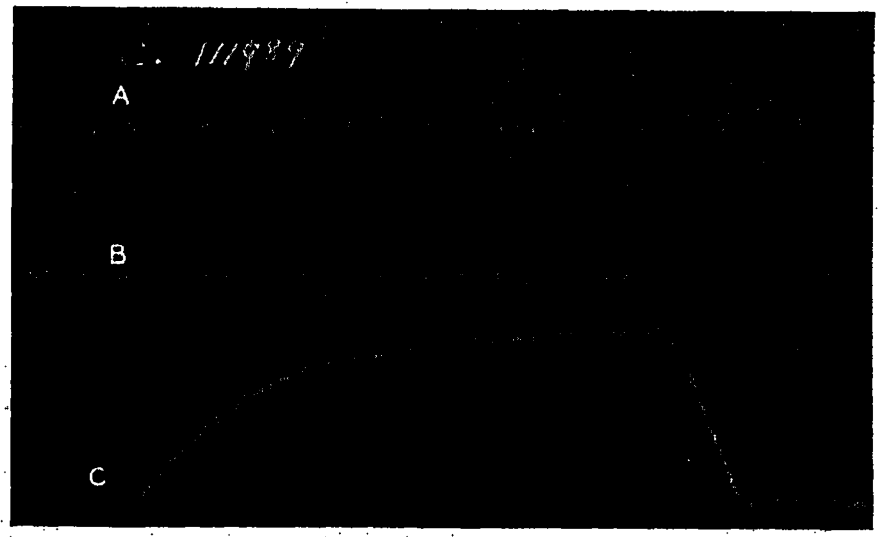

Fig. 3. Oscillograph record of 3,000-volt main fuse rupturing 3,040-ampere inductive circuit

A—60-cycle timing wave; B—Line voltage; C—Line current

The oscillograph record of test 3 is shown in Fig. 5. Interruption tests were made with 2 contactors in series with the following results:

10 interruptions in 2 min. with 3,300-volt 1,500-ampere inductive load.

5 interruptions in 2 min. with 3,300-volt 3,000-ampere non-inductive load.

On account of the liberal design of the line breaker contactors the heating for the service in which they are used is very low. A continuous heat run at 270 amperes gave the following temperatures:

| | |
|---|---|
| Blowout coil | 84 deg. cent. rise |
| Contact tips | 45 deg. cent. rise |
| Flexible shunts | 38 deg. cent. rise |
| Magnet valve coil (operating at 40 volts) | 30 deg. cent. rise |

The line breaker, because of the high voltage circuit and its location on the car, was designed to be grounded to insure safety to any passenger or workman who might come in contact with the box. Grounding this box necessitated some radical changes in insulation and box construction quite different from previous designs on which it has been customary to insulate the enclosing cases.

## Motor Controller and Associated Equipment

The motor controller, consisting of a group of devices assembled in a box for mounting underneath the car, is the principal part of the motor control apparatus. The box is made of fabricated steel with welded joints. Top covers are fixed and all side and end covers are hinged and latched. Cables enter the box at the top through 2-piece wood cleats. The equipment is mounted underneath the car with the box grounded to the car underframe.

A view of the front of the motor controller with the arc chutes of the cam contactors removed is presented in Fig. 6; at the right are the motor cutout switches and on the left are mounted the main air engine and relays. This motor controller contains:

7 cam operated resistance contactors.
3 cam operated contactors for series-paralleling the motor group.
1 main air engine for operating the cam shaft.
1 motor reverser.
2 motor cutout switches.
1 potential or no-voltage relay.
1 accelerating relay.
1 field control relay.

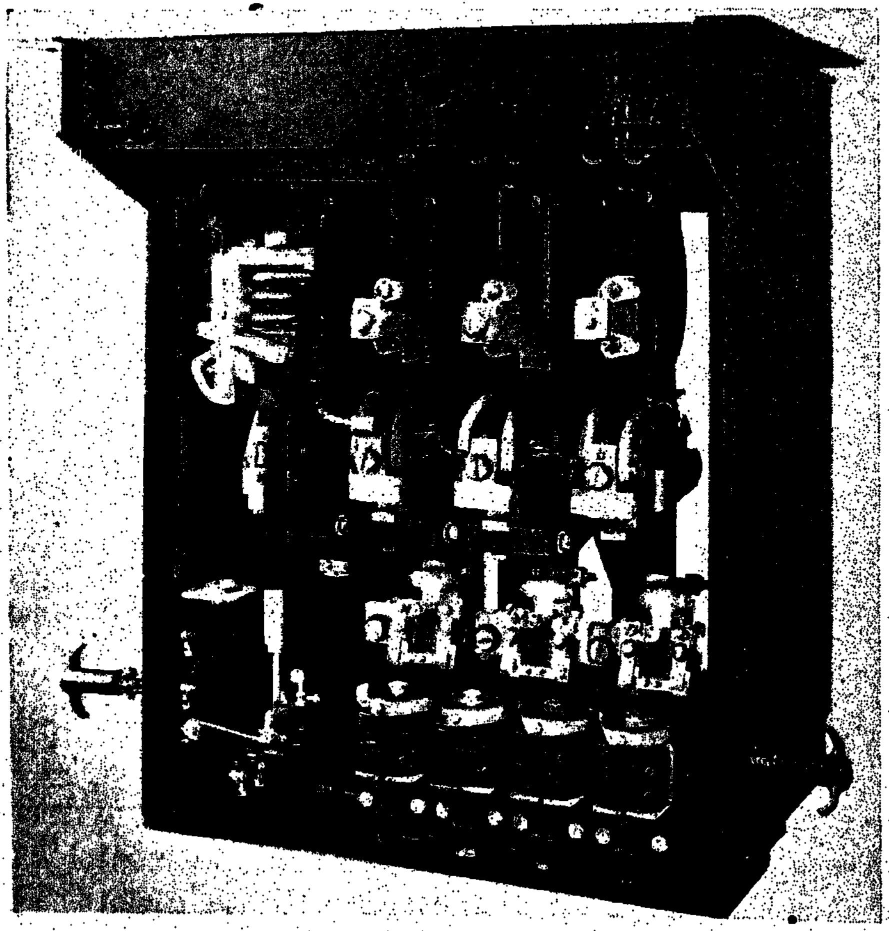

Fig. 4. Rear view of 3,000-volt line breaker

The cam contactors, one of which is shown in Fig. 7, have current carrying parts clamped on a rectangular steel bar which is covered by wrapped insulation. All contactors have magnetic blowout. Current carrying parts are of brass and both upper and lower contact tips are provided with arcing horns. Individual arc chutes can be removed by loosening a single screw at the top of the contactor and rotating the locking mechanism.

Contactors are closed by cams bearing upon a steel roller; they are opened by the pressure of the contact spring and by gravity. Should a contactor tip stick or "freeze," a mechanically operated "knock-out" operates on the cam shaft and mechanically forces the contactor open. Contactors have a 1-in. tip gap and renewable contact tips $^3/_4$ in. wide; contact tip pressure is 16 lb. Two of the contactors (R6 and S in Fig. 1) have enlarged arc chutes vented to the outside of the box as these contactors under some conditions are required to break current. The cam shaft is of hexagonal steel with wrapped mica insulation, cast iron cams being clamped on over the insulation and separated by insulating collars.

An opposed-cylinder air engine operates the cam shaft through a rack and pinion. Air admitted to the "on" cylinder rotates the cam shaft to the "on" position while air admitted to the "off" cylinder stops the progression on any step. Admission of air to the "off" cylinder is governed by a magnet valve under control of the accelerating relay which permits the cam shaft to rotate step by step under the influence of the current through the motors; this maintains a constant average current during acceleration. A specially designed accelerating relay also provides means to enable the operator to advance the motor controller one step at a time regardless of the motor current.

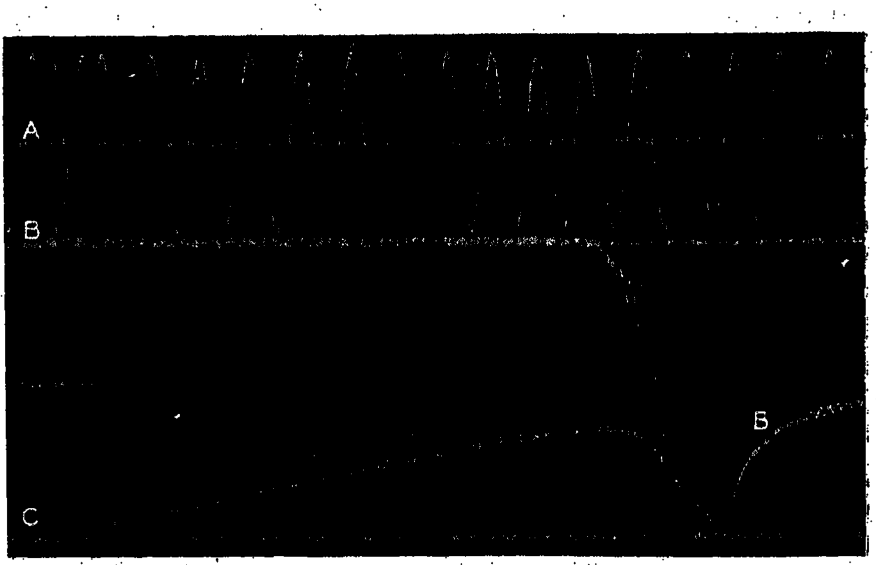

Fig. 5. Oscillograph record of 3,000-volt line breaker rupturing 1,500 ampere inductive circuit

A—60-cycle timing wave; B—Line voltage; C—Line current

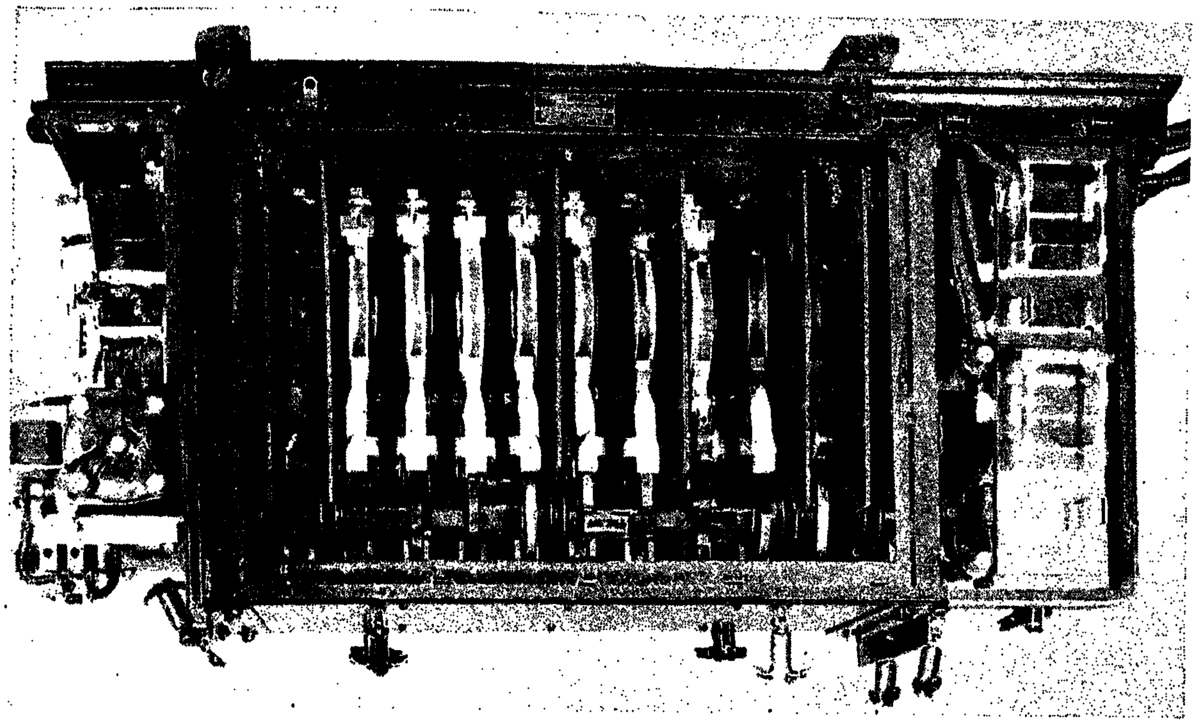

Fig. 6. Front view of motor controller with contactor arc chutes removed

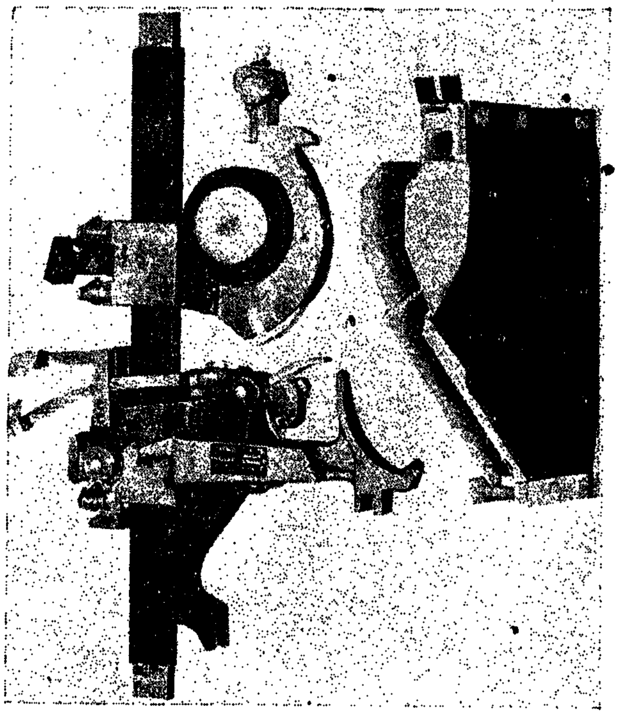

Fig. 7. Cam operated 3,000-volt contactor

Field connections of the motors are reversed by an electropneumatic reverser mounted in one end of the motor controller. It is of the cylinder type with segment castings mounted on an insulated hexagonal shaft. A double cylinder air engine furnishes power to rotate the cylinder to either the forward or the reverse position.

In addition to the accelerating relay there are provided (1) a second relay to govern the closing of the field control switches, and (2) a potential relay with resistor tubes to cut off the control current on an individual car should the line potential fail. The potential relay closes at 1,300 volts and opens if the potential falls to 750 volts.

## Field Strength Reduced by Inductive Shunts

The fields of the motors are shunted by an inductive shunt giving a reduced field strength of 50 per cent. In series with the inductive shunt is an adjustable non-inductive resistance to compensate for any variation in the wiring of the 2 pairs of motors. A separate box with 2 contactors operated by a single air cylinder and having mounted in the back 2 adjustable rheostats composed of edgewise wound units comprise the equipment for shunting the fields.

Main resistors are of the edgewise wound type arranged in 1 group of 2 sections, and 1 group of 3 sections. All of the resistance is connected in the circuit on the trolley side of the motors. The alloy of which the resistors are wound has a high specific resistance, 120 × $10^{-6}$ ohms per cm.$^3$, but a low temperature coefficient of resistance; the increase in resistance is 5.8 per cent with 350 deg. cent. rise in temperature. The resistor frames are insulated from the support by 1,500-volt porcelain bolt insulators; the support is insulated from the car framework by 3,000-volt porcelain bolt insulators.

## Master Controller and Cab Equipment

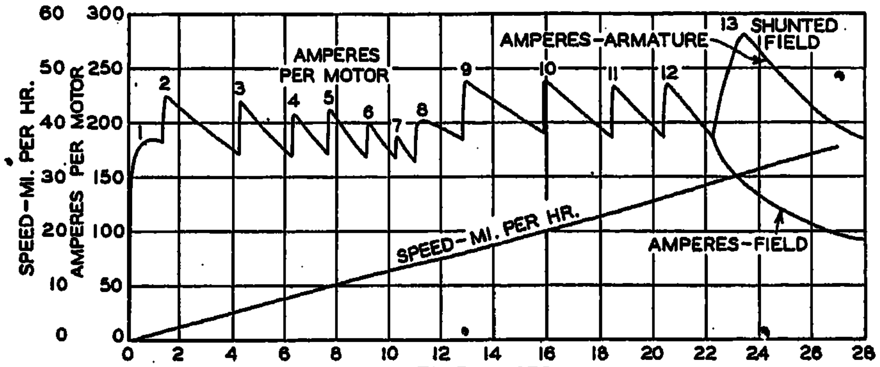

Fig. 8. Acceleration curve of Lackawanna 3,000-volt d-c. multiple unit cars

The master controller has 2 cylinders, a main and a reverse. A "dead man's release and emergency brake feature" is incorporated in the controller which interrupts the control current and actuates a pilot valve to apply the emergency air brakes should the handle be released.

A button type switch in each cab gives the operator convenient control over the pantographs, control equipment, overload reset, dynamotor, heaters, and lights. It is provided with a lock so arranged that all important circuit switches are locked in a fixed position when the key is removed. An additional control switch is connected to the air brake cutout cock; this switch cuts off all control current to the master controller unless the cutout cock is open, thus preventing the starting of the train until the air brakes have been cut in.

## Tests

A sample unit consisting of a motor car and a trail car was completely equipped with motors, control, and air brakes, for test purposes. These cars were run for 15,000 miles on the 3,000-volt test track at Erie, Pa., to determine how they would perform under service conditions.

The production control apparatus was subjected to many special tests. In addition, all control devices for 3,000-volt circuits were given a high potential test of 8,750 volts at 60 cycles for 1 min.; all control devices for the 32-volt circuits were tested at 1,000 volts, 60 cycles for 1 min.

# Sectionalizing Improves Rectifier Efficiency

**By building large capacity mercury arc rectifiers from a group of several small sections, the better efficiency, reliability, economy, and flexibility inherent in the smaller rectifiers can be retained in the larger units. Experiments on a 3,000-kw. rectifier composed of 4 750-kw. units, shows an efficiency one per cent higher than for the conventional single unit type.**

By
A. L. ATHERTON
MEMBER A.I.E.E.

Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

PRACTICABILITY of the sectional type of mercury arc rectifier is based upon the obvious, but apparently heretofore unrecognized, fact that the best possibilities inherent in the device are realized only in the smaller sizes. Efficiency, reliability, economy, and flexibility of both application and use are all far better in small than in large units. Furthermore, the advantages appear to be fundamental and therefore permanent. Subdividing a mercury arc rectifier into unit sections introduces both advantages and disadvantages; but the advantages so far outweigh the disadvantages that, once the conception is considered seriously and the sectional design actually worked out, doubts disappear and sectionalized plan seems the right and natural one to adopt.

Development through the past 29 years has resulted in rectifiers of small capacity, 500 kw. for example, with a high degree of reliability, a reasonable cost, and an efficiency which makes available for the higher voltage applications the unique quietness and freedom from mechanical wear which has been the major incentive throughout the development. When size is increased, however, the quality decreases markedly. Reliability decreases not in proportion to size, but more rapidly because the difficulty of controlling the "hurricane" flow of vapor from the cathode is increased enormously when the size is even doubled. The outage time of 3,000-kw. rectifiers is several times as great as that of 500-kw. units. Cost per unit output does not decrease with increase of size, as it does with some apparatus; this is because manufacturing problems increase faster than in proportion to size, and because the total requirement for this kind of equipment with capabilities and limitations as they are, even in the smaller sizes, will not support organized "line manufacture" for the larger capacities. Efficiency falls off with increase in size because of the longer arc and greater exposure to deionizing surfaces, and because to obtain acceptable quantity the fundamentally less reliability makes necessary an increase in loss-producing arc-back preventives. With present designs, internal losses per unit output for a 500-kw. rectifier are only about $^3/_4$ of those for a 3,000-kw. unit, both based upon 600-volt operation.

## DISADVANTAGES OF LARGE UNITS FUNDAMENTAL

The major disadvantages which go with size appear to be fundamental and permanent, whatever advances may be made. Larger units always will be less efficient, and the reliability and cost disadvantages probably will persist.

Multiple installations of conventional small capacity units of the sort available in the past are impracticable; the space required is too great and the multiplicity of control and protective devices appears highly undesirable. But if a rectifier of large capacity is subdivided so as to take advantage of space economies resulting from recent advances in the art, building the structure in sections but installing, controlling, protecting and using it as a whole, the project becomes feasible; the desirable qualities of the small rectifier are made available for the larger capacities while the disadvantages of sectionalizing are reduced so as to become negligible.

Research in the Westinghouse laboratories on rectifiers of conventional size and characteristics has shown that the limitation in capacity for a given design lies in local limitations of the various parts, for example, the limits of conductivity and heating at the anode, and not in the fundamental and perhaps more troublesome tendency to arc back at the higher currents. To illustrate this the 500-kw. rectifier shown in Fig. 1 carries a nominal current of 833 amperes continuously, 1,250 amperes for 2 hr., and 2,500 amperes for 1 min.; extensive tests, which include use at currents up to 17,000 amperes on short circuit and loads of 2,000 to 2,500 amperes for periods of 5 to 30 min., depending on temperature rise, have not shown arc-back to be a limitation. Extended service experience with a limited number of installations gives the same result. Evidently, changes in the details leaving the general arrangement unaltered, would make it possible to reduce materially the size of the containing tank without affecting the ability of the unit to carry the loads required. Experiments have verified this conclusion.

## SIZE REDUCED BY REARRANGING PARTS

As a further step, a rearrangement of parts made possible a still further reduction in size for a given rating, and at the same time brought about some reduction in the internal losses. The rearrangement was based upon knowledge gained from experiments made to determine: (1) the effect of the way the vapor flows from cathode to condensing wall; and

---

Based upon "High Capacity Rectifier Efficiency Improves by Sectionalizing" (No. 32-50) presented at the A.I.E.E. winter convention, New York, N. Y., Jan. 25–29, 1932.

(2) the effect of the position of the anode structures in relation to this stream of ionized vapor upon the limiting current of which the rectifier unit is capable without excessive arcing-back. Although the whole mechanism of vapor flow and its effect on arc-back still are obscure, several factors that influence performance have been established. In the design shown in Fig. 2 an attempt has been made to take into account in the most satisfactory way possible at the present time, these as yet rather intangible and, it must be admitted, somewhat uncertain factors.

The desirability of improving the anode support and shielding arrangement also offered an opportunity for progress; a rather extended series of experiments resulted finally in the anode structure shown in Fig. 2. Processing to eliminate foreign material and to keep the gas evolution in operation at as low a value as possible, have progressed along with the design development.

As a result of these improvements, the rectifier section shown in Fig. 2 is capable, with a reasonable margin, of a standard nominal rating of 750 kw. at 600 volts, and of even higher short-time overloads at this rating. The unit is required to carry a normal current of 1,250 amperes, and 50 per cent overload, or 1,875 amperes for 2 hr. Since final temperatures are reached in about 2 hr., it is felt that the 2 hr. capacity can best be indicated by continuous operation at the 50-per cent overload value; experimental tests have been made in this way, thus including in a single test some margin of safety along with a degree of acceleration of the test. Double load, or 2,500 amperes, is required by standard nominal rating for a period of 1 min. following full load; experimental tests have been made at this current for a duration as long as 5 min. In all these operations, arc-back is quite infrequent; furthermore, it is a requirement that the rectifier can be put into operation again immediately following such an occurrence.

## Arc-Drop Lower in Sectionalized Rectifiers

Internal losses in the rectifier are determined by the arc-drop, or voltage from anode to cathode during the conducting period; this voltage varies with load current. The value that determines the rectifier efficiency is the average for the various anodes. Fig. 3 shows an average arc-drop curve for both the unit indicated by Fig. 2 and the older, conventional unit shown in Fig. 1. As the size of a rectifier is increased, the arc path becomes longer, resulting in increased exposure to deionizing surfaces; thus the losses per unit output become greater. Experimental rectifiers of 3,000 kw. with a single tank have had arc-drop voltages as shown by the dot-dash curve of Fig. 3. It may be seen that at full loads the difference between the arc-drop voltage of these experimental single-tank 3,000-kw. rectifiers and that of the sectional units shown in Fig. 2 amounts at full load to approximately 6 volts or 1 per cent, on the basis of a 600-volt output. With ordinary load factors and power costs, a 3,000-kw. sectionalized rectifier thus could be operated for from $600 to $1,500 less per year in power cost than could a single-unit rectifier of this capacity; this saving would justify an added investment of from $4,000 to $10,000.

Physical proportions of the sectional units are such as to make it feasible to mount them in service one above another. Thus, a 3,000-kw. unit can be made of 4 750-kw. sections mounted 2 side by side and 2 high, as shown in Fig. 4. Floor space required for such an assembly is approximately 118 in. wide, by 68 in. deep, overall, including auxiliary equipment. The over-all height is 113 in. and the necessary ceiling height of a room to accommodate this equipment need not exceed this value except for electrical clearance of a few inches and whatever may be necessary to provide for adequate working space, certainly not more than 2 ft. It is evident that the sectionalized plan thus makes possible a

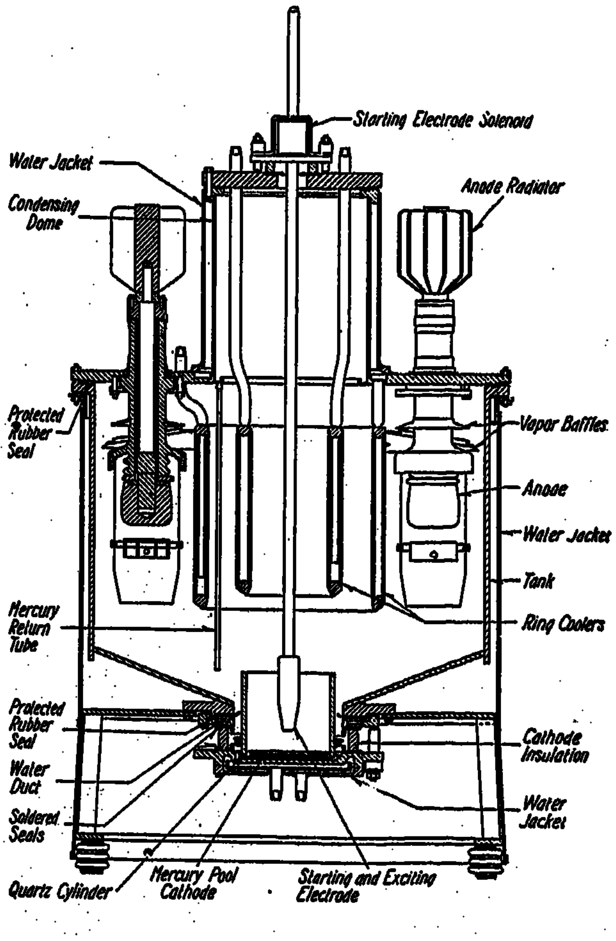

**Fig. 1. (Left) Sectional view of a conventional 500-kw. 600-volt rectifier**

The diameter of each of the 2 units is 54 in.; over-all height of the conventional rectifier shown on the left is 104 in. while that for sectional unit shown on the right is 41.5 in. The kw. rating per unit volume for the sectional unit is thus more than 3 times as great as for the conventional unit

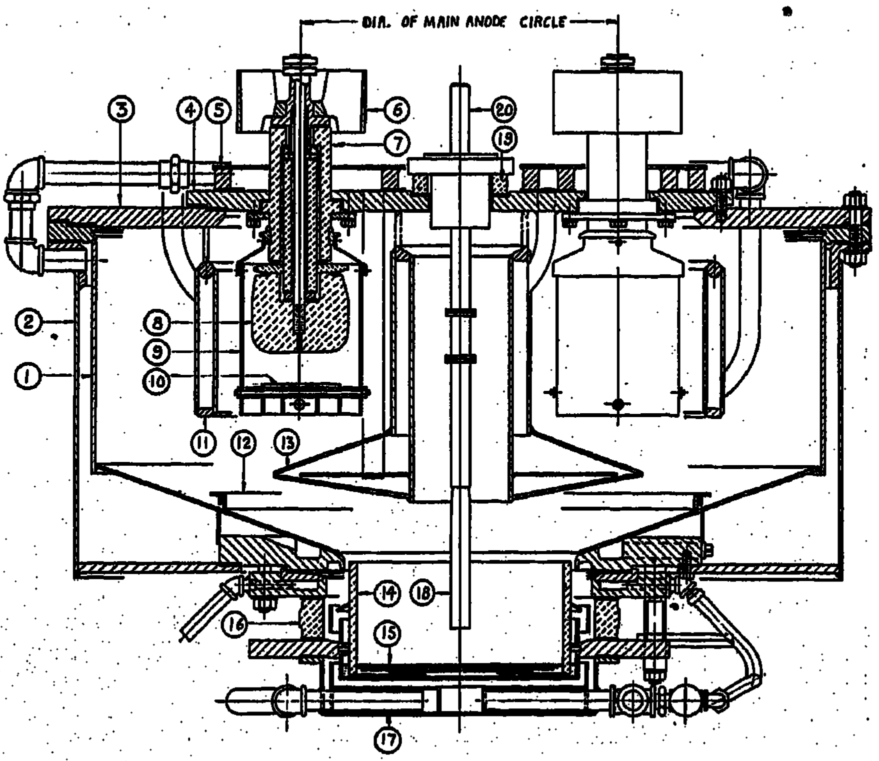

**Fig. 2. Sectional view of an improved 750-kw. 600-volt rectifier unit**

considerable saving in space. Such an arrangement is likely to prove the most convenient for usual applications. There is no reason, however, why other arrangements cannot be used where available space places a limitation on one or more dimensions.

### PARALLELING SECTIONS NO NEW PROBLEM

The problem of paralleling is the same for sectional rectifier units as for a single tank rectifier using the same number of anodes and, except in detail, is the same for any rectifier using twelve or more anodes. Load balancing is inherently approximately correct because the voltage across the arc rises with increasing current after a minimum at about 40 per cent load. To get a closer balance, anode balancing coils are used; these are arranged so as to introduce no appreciable impedance into the circuit under normal operation. Should it be desired to take a section out of service, for maintenance or any other reason, the corresponding balancing coil sections are short circuited by connecting links provided for the purpose.

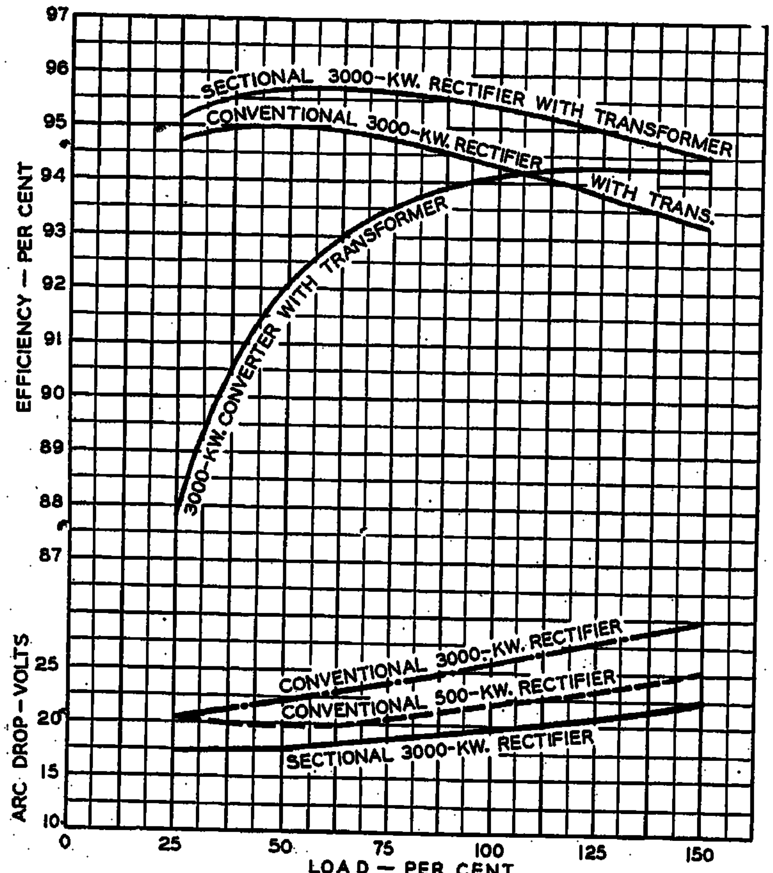

Fig. 3. Comparative characteristic curves for single unit and sectional rectifiers

One arrangement of vacuum pumping for sectional units is indicated in Fig. 5. Use is made of 2 independent pumping systems, connected through manifolding to the various sections and with cross connections so arranged as to permit the use of either pumping system or any or all of the tanks. The various sections of the rectifier are connected to the vacuum manifold through 2 valves of unique design, provided with a sealing plate as an extra precaution against outside air. Even if such a valve should develop a leak, this safeguard would prevent any leakage into the tanks except at a slow rate and only for the minute or less while the valve position is being changed. The use of 2 valves permits the separation of a single section from the balance of the structure without admitting air to either part. When maintenance work is required, it is thus possible to put the repaired section in condition by pretreatment, then install it and, by proper manipulation of the valves, exhaust it completely without admitting air to either the unit or any part of the operating system. With the pumping arrangement shown, this requires the operation of one of the other units with valves closed for some time. This introduces no further difficulty, however, for experience has indicated that if properly made and treated out the rectifier unit will carry normal loads without pumping for several hours or even several days without damage.

Sectionalizing inherently provides the utility

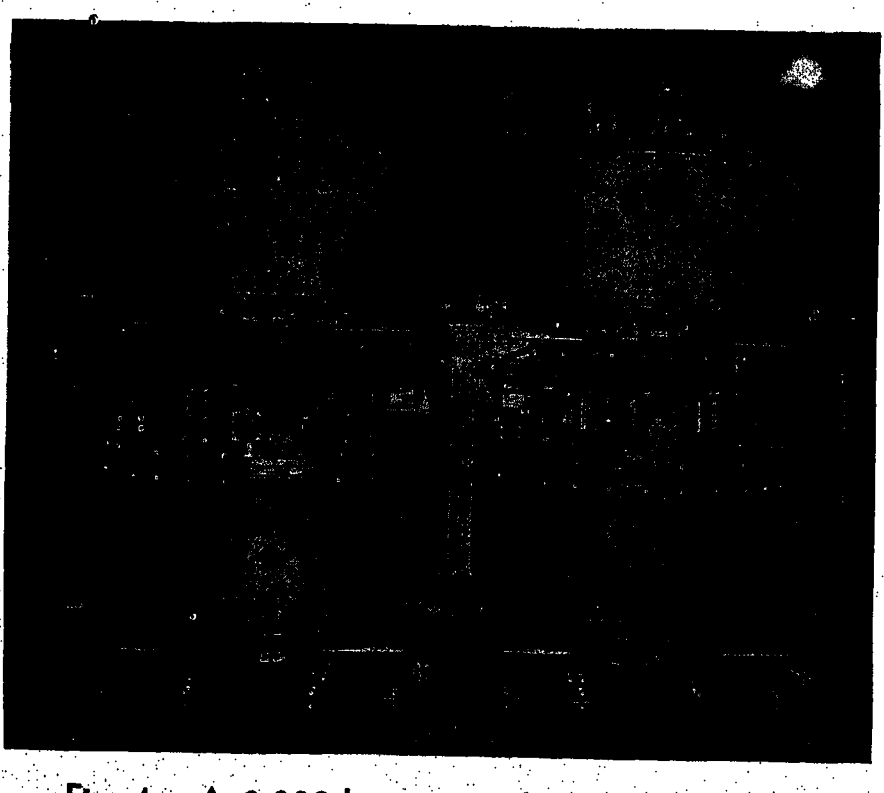

Fig. 4. A 3,000-kw. sectional rectifier composed of 4 750-kw. units

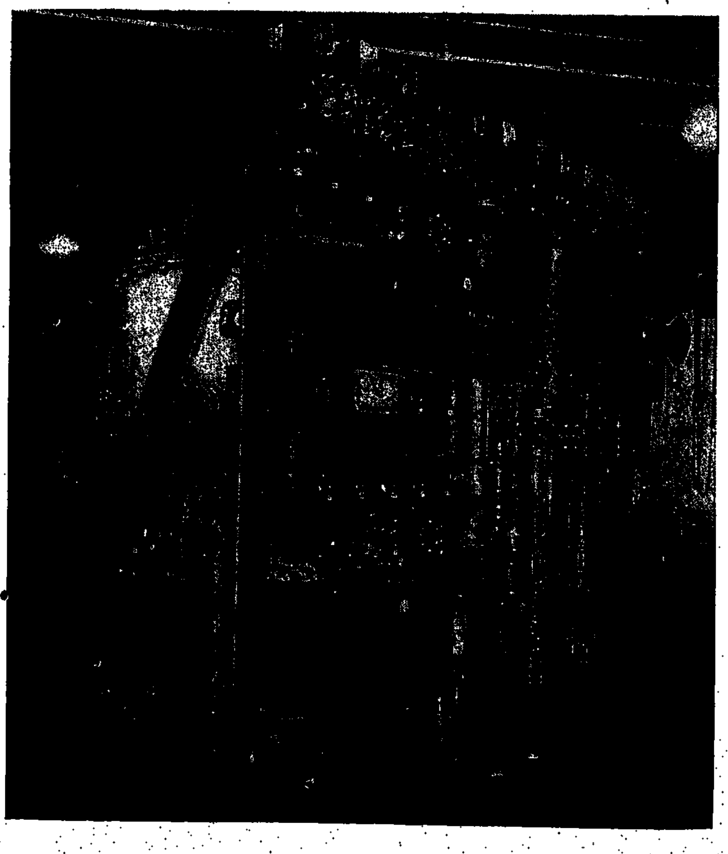

Fig. 5. Rear view of 3,000-kw. 600-volt 4-unit sectional rectifier showing arrangement for maintaining the vacuum

that any damage is likely to be limited to a relatively small part of the total assembly and that during the period of maintenance the load can be carried by the remaining units. With the arrangement shown in Fig. 5, a faulty section can be segregated from the others by removing the connecting links and closing the valves, requiring only a few minutes, before load can be carried again. Although the maintenance operation to remove a unit from the structure for repairs requires as long as 2 hr. or more, this can be done during a light or no load period. It would be possible to arrange with jack connections and separate systems of auxiliary equipment or flexible pumping and water connections, so that the operator could pull the unit forward a few inches and go on with operation with the remainder of the equipment after an interruption of 1 or 2 min. Choice between these 2 plans depends upon cost and service requirements.

The sectionalized plan applied to mercury arc rectifiers, together with development work already performed in designing improved sectional units of more suitable dimensions and proportions, have made available in this equipment increased reliability, increased flexibility in application and use, improvement in manufacturing requirements, and an efficiency advantage of one per cent or more. Beyond this is the belief that further improvements will be made as time goes on and as a clearer understanding is acquired of the fundamental knowledge gained from research. It is to be expected that future developments will progress along the lines of sectional structures rather than single unit arrangements.

# An Improved Gap for Station Apparatus

**An improved voltage limiting gap for protecting electric power station apparatus has been developed, the breakdown characteristics of which may be varied over a wide range so as to conform to the characteristics of the station insulation. For the best protection, a lightning arrester in parallel with the gap is recommended.**

By
A. O. AUSTIN
FELLOW A.I.E.E.

Ohio Brass Co.,
Mansfield, Ohio

RECORDS as well as operating experience show that electric power stations may be subjected to a wide variety of transients. Although in practise it is necessary to limit the magnitude of the transients which may cause damage to the equipment, it is desirable that any limiting device shall not function unnecessarily, thereby causing interruptions. This is particularly true where a protecting gap is used that has not the ability to clear the line or prevent the flow of normal frequency current following discharge. This leads to the use of a limiting gap of relatively small time lag for transients of extremely high magnitude and steep front, in parallel with an arrester of greater time lag that will function for the many transients of lower magnitude without interrupting service.

It is exceedingly difficult to coordinate station insulation for the wide range of transients likely to be imposed, as the impulse flashover characteristics may be quite different as regards time lag and polarity, even though these characteristics be in close agreement at normal frequency. This is evident by reference to Fig. 1.

Owing to difference in time lag, a high overpotential suddenly applied may cause one type of insulator to flashover, whereas a transient having a much lower crest value may cause another insulator to flashover. Furthermore, the difference between the

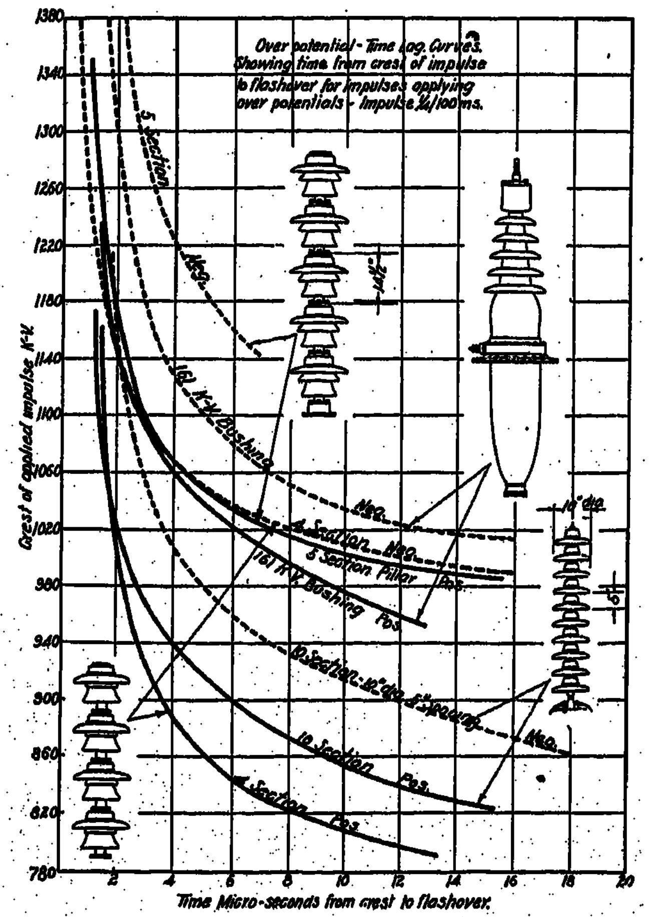

Fig. 1. Impulse flashover characteristics for different types of insulators

---

Based upon "Improved Type of Limiting Gap for Protecting Station Apparatus" (No. 32-60) presented at the A.I.E.E. Great Lakes District meeting, Milwaukee, Wis., March 14–16, 1932.

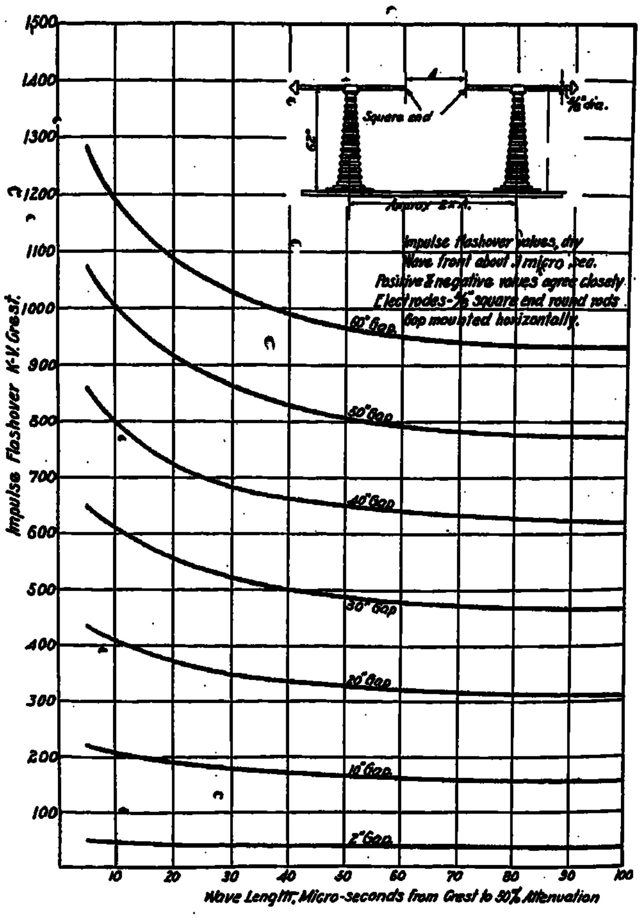

**Fig. 2. (Left) Impulse flashover characteristics for a simple type of gap**

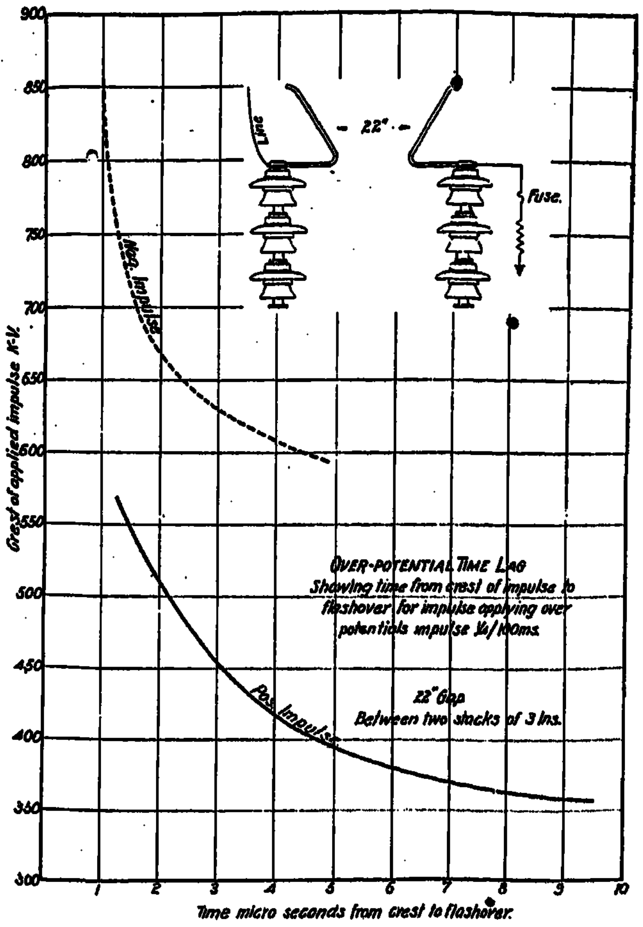

**Fig. 3. (Right) Positive and negative impulse flashover characteristics for a typical horn-gap**

breakdown voltage for negative and positive transients, respectively, may be quite large for bushings, bus insulators, and the internal insulation of transformers and circuit breakers. A bus insulation or a disconnecting switch may have a high effective flashover voltage for a negative impulse, and a much lower value for a positive impulse; for some other piece of equipment the reverse may be true. In station insulation therefore it is necessary to take into account not only the time lag in flashover, but the effect of polarity and oscillations as well.

A lightning arrester or a limiting gap which will protect station insulation against overvoltage transients long has been regarded of great economic importance. It is evident that if a gap or lightning arrester may be depended upon to protect the insulation in a manner similar to that in which a safety valve protects a boiler, it is possible to lower the level of insulation and thereby effect a material saving. To be fully effective, however, the limiting device must interrupt the discharge when the overvoltage is relieved, without interfering with operation.

## CHARACTERISTICS OF LIMITING GAPS

Impulse flashover voltages for a simple type of gap formed by two $^5/_8$-in. rods are shown in Fig. 2; Fig. 3 shows the time lag characteristics for a 22-in. horn-gap. In considering the characteristics of these gaps, it may be noted that the flashover voltage tends to increase rapidly for short waves or for short time intervals. Since equipment needs protection most for severe direct strokes at or in the immediate vicinity of the station, many gaps may not afford the desired protection, although having an arcing voltage comparatively low for less severe impulses or those of longer duration. Also the characteristics of some gaps for positive impulses may be widely different from those for negative impulses. If therefore the gap is to furnish efficient protection, it must have characteristics corresponding to those of the insulation in parallel with it, both with respect to polarity and to time lag.

Impulse time lag characteristics for a typical bushing and several types of limiting gaps are shown in Fig. 4; to avoid confusion, curves for only one polarity are shown. In order to provide protection for the bushing having the characteristics shown in curve *A*, it may be assumed that the voltage limiting gap should flashover at not more than 90 per cent of *A* for all time lags indicated by curve *B*. The characteristic curve of the horn-gap shown as *C* has approximately the same shape as *A*, although it tends to depart somewhat for the shorter time lags. Reference to Fig. 3, however, shows that for that type of gap, the difference between positive and negative sparkover voltages is likely to be very large.

Referring again to Fig. 4 it may be noted that curve *D* for the ring-gap intersects curve *A* at approximately 585 kv. For transients having a crest below 585 kv., the ring-gap will sparkover first; for transients having crest values above 585 kv., however, the ring-gap does not afford protection, as the bushing will sparkover first. Therefore if the ring-gap is set as high as possible so as to minimize unnecessary interruption for transients of lower crest and longer duration, it will afford little or no protection for severe overvoltages when most needed. To provide protection against these severe overvoltages, the ring spacing and flashover voltage must be materially reduced, thereby causing unnecessary interruptions. For example, the minimum flashover voltage shown in Fig. 4 for the ring-gap is approximately 400 kv., as against 520 kv. for the bushing; a further reduction in the flashover voltage of the ring-gap is necessary in order to provide protection for high over-potentials.

Curve *E* of Fig. 4 shows the characteristics of a sphere-gap of negligible time lag having the same minimum flashover voltage as the gap of curve *B*.

As the time of voltage applications is decreased, however, insulators and most equipment will withstand much higher impulses. It is desirable therefore that the impulse flashover of the limiting gap be higher for short time lags. If a limiting gap having the rather uniform flashover characteristics of a sphere-gap as shown by curve *E* is used, unnecessary flashovers will result owing to the sparkover of the gap for the shorter time lags where the insulation can well withstand higher voltages. Characteristics of the sphere-gap may be modified materially by changing the relative sizes of the spheres with respect to each other and with respect to the gap spacing. As will be discussed later, this principle is made use of in the control type of gap to obtain the characteristic of curve *A′*, closely approximating the ideal characteristic curve *B*.

## CONTROL TYPE OF LIMITING GAP

A protecting gap will approach the ideal in so far as the following can be carried out:

1. It should be possible to control the time lag characteristics so that the gap will afford protection over the range of transients likely to be imposed.
2. Negative and positive impulse breakdown characteristics of the protecting gap should correspond to that of the apparatus to be protected.
3. Flashover voltage of the gap should not be lowered seriously by rain or surface contaminations.
4. Means should be provided for changing the relative negative and positive flashover voltages, where it is desired to work within close limits or to protect apparatus or insulation, the properties of which are not fully known.
5. It should be possible to change the time lag characteristics without materially affecting the minimum flashover voltage.
6. Where discharge of the gap will cause a serious service interruption, a fuse or other device should be used for clearing the normal-frequency current following discharge.
7. The gap should not discharge under high frequency transients of comparatively low magnitude caused by switching or arcing grounds.

A gap conforming to these requirements obviously should have improved characteristics over types in general use in the past; development of such a gap is described in the following paragraphs.

A protecting gap using spheres of proper size in relation to the gap spacing and of unequal diameters to provide for the difference in negative and positive characteristics of the equipment protected could be used to comply with requirements 1 and 2 just enumerated. However, the effect of water or other surface contaminations upon the flashover voltage of spheres would make it difficult to conform to requirement 3. Also the characteristics of the gap made in this way could not be changed easily and therefore would not meet the requirements 4 and 5.

As the spacing of a protecting sphere-gap is increased to lengths well beyond the diameter of the spheres, the flashover voltage for a positive impulse will tend to be lower than for a negative impulse. This can be offset by using a larger sphere for the live terminal and a smaller one for the ground terminal. Where the electrostatic fields of the two terminals of the gap are of equal intensity, the flashover will start from the positive terminal since a lower density is required to start discharge with a positively charged electrode. Therefore by controlling the flux density at the surface of a gap terminal, it is possible to vary the discharge voltage. This principle is made use of in the newly developed limiting gap, one form of which is shown in Fig. 4. The control shields in the vicinity of the gap terminals can be moved forward or backward to change the field density and regulate not only the time lag but the difference in negative and positive sparkover characteristics.

Test results (see Fig. 5) show that the relative negative and positive flashover voltages of the protecting gap may be controlled readily by changing the flux density of the positive arcing tip. Any screen or shield may be used to accomplish this. It is important, however, that the shield does not cause erratic performance by becoming one of the electrodes so that an arc will be struck between shields

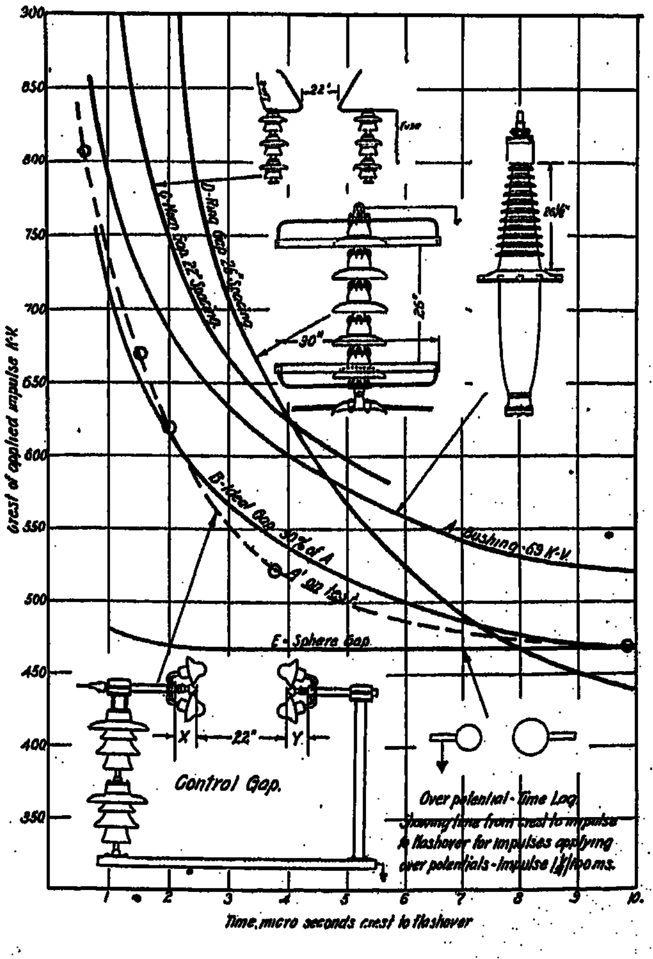

**Fig. 4. (Left) Comparative impulse flashover characteristics for various gaps**

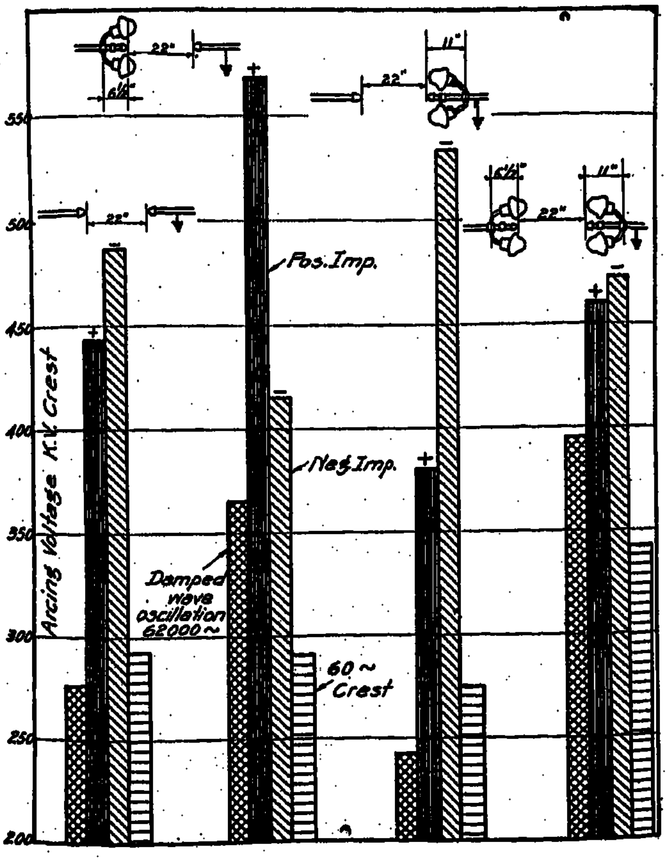

**Fig. 5. (Right) Chart showing effect of insulated control screens upon arcing voltages of a 22-in. gap**

or between one of the tips and a shield. By using the insulated type of shield this difficulty is obviated, even though the shields may be nearer together than the discharge points. This is particularly important in wet conditions or where the gap may be subjected to high frequency oscillations, for in these circumstances a gap having bare metal shields generally has a very low flashover voltage. Reference to Fig. 5 shows that control of the flux density of the discharge points by means of the insulated shields is quite effective in changing the relative arc overvoltage for negative and positive impulses. In addition it may be seen that the arcing voltage for a damped wave or oscillation compares favorably with that for an impulse, thereby reducing unnecessary discharges.

The change in relative negative and positive impulse sparkover voltages that may be effected by changing the flux density on the electrodes with insulated control shields is shown by Fig. 6 as well as Fig. 5. Reference to Fig. 6 shows that the arcing voltage for a negative impulse is approximately 75 per cent greater than for a positive impulse where the controlled screens have the same relation to the arcing tips, and where the control screens are well forward ($C = 3$ in.). Moving the control shield on the ground electrode back from the point of the gap reduces the screening on this electrode so that the discharge will start at a lower voltage for a given distance between terminals when the opposite terminal is negative. Moving the shield back on the ground side also reduces the flux on the live terminal so that the arcing voltage for a positive impulse will be raised. For example, by increasing $C$ to 9 in. and reducing the screening effect of the control shield on the ground electrode, the positive and negative impulse values are brought in close agreement. Advancing the control screen on the live side toward the gap opening has the same general polarity effect as moving the control screen on the ground side away from the gap opening.

It is evident that the arcing voltage will be increased for a given gap spacing if the stress on the arcing tips is reduced by advancing the control shields; this makes it possible to reduce the gap spacing and time lag for a given flashover voltage. It necessarily follows that the characteristics of the gap may be changed materially, both as to time lag and the effect of polarity upon discharge voltage, by simply adjusting the control shields. As the projecting insulated control screen is affected but little by high frequency transients, it is possible to reduce the time lag without lowering the flashover voltage for waves of lower crest and long duration. In Fig. 7 the impulse flashover values for waves of different attenuation are given for a control type of gap and a ring equipped suspension string, respectively.

Control gaps of this type may be made in several different forms with plain shields or rings used in place of the insulated control screen. The latter has the advantage in that the gap does not have a low flashover voltage for oscillations and is affected but little by rain or conditions which may cause a gap with a bare metal shield to be erratic. Other forms of gaps embodying the principles outlined in some cases may work out to much better advantage.

## CONCLUSIONS

Results of this study and development work indicate that:

1. An ideal voltage limiting gap for station use is one wherein both polarity and time lag characteristics are capable of adjustment over a sufficient range to allow protection of all apparatus in parallel with it for any transient wave form imposed upon the station.

2. A form of limiting gap has been developed, making use of adjustable electrostatic field controls for the gap electrodes. This allows the breakdown characteristics of the gap both as to time lag and arcing voltage for positive and negative impressed waves, to be varied over a wide range so as to conform to the characteristics of the station insulation.

3. The use of a control type of gap for limiting the severest transients only, and a lightning arrester for the remainder, undoubtedly will provide the best station protection and operation available at present.

# Abstracts

## Of Papers to Be Presented at the Pacific Coast Convention

INTERPRETIVE abstracts of all papers which at the time of this issue are definitely scheduled for presentation at the A.I.E.E. Pacific Coast convention (Aug. 30–Sept. 2, 1932) are published herewith. In response to popular demand and within its space limitations ELECTRICAL ENGINEERING subsequently may publish certain of these papers, or technical articles based upon them.

Members vitally interested and wishing to obtain a pamphlet copy of any paper available in that form may do so by writing to the A.I.E.E. Order Dept., 33 West 39th Street, New York, N. Y., stating title, author, and publication number of each paper desired.

### The Power System of the British Columbia Power Corporation, Ltd.

By
E. E. Carpenter[1]

THE SYSTEM LOAD of the British Columbia Power Corporation, Ltd., is concerned principally with lighting, domestic power, and small industrial power. With one exception no heavy contract load is carried. Owing to the seasonal and climatic influences the load factors are inherently low, the annual load factor ranging for several years between 45 and 48 per cent, with little immediate prospect of improvement. The peak load on this system, during the middle of December, is 100,800 kw.

The power supply for the system is derived principally from hydro sources although 3 steam plants are maintained for standby, emergency, and occasional peak service. The coastal region especially is favored in water power resources, although precipitation increases rapidly with altitudes any distance from the coast. Snow and ice on the higher elevations and dense forest growth over a large part of the area have a considerable effect on the power supply, while the glacial structure and topography lend their aid to providing favorable dam sites and storage basins for regulation, a necessary and expensive part of all the developments.

Details of the electric, hydraulic, and structural features of the principal generating plants of the system are described briefly in this paper, and the transmission and distribution system is summarized. (For presentation only; not scheduled for publication by the Institute.)

### Segregation of Hydroelectric Power Costs

By
W. S. McCrea, Jr.[3]

THE PRODUCTION COST of electric power is made up of the power or demand cost per kilowatt and the energy cost per kilowatt-hour. The relative amount of each of these items which make up the total cost of power at the power station determines the cost at any load factor. The above segregation of the annual production cost of power is essential in determining the power rates and the economic design of the production plants of an electric system.

The usual hydroelectric power station is designed to utilize as much of the potential stream flow energy as is possible economically with the type of load available. The annual costs of such a station having storage may be divided between those costs proportional to the generating capacity and those independent of the generating capacity. For use in the design of the station the energy available in the stream is fixed at some value, and is determined by the stream flow records. The energy cost of hydroelectric power from this type of station is the annual costs which are independent of the generating capacity divided by the useful stream flow energy. The demand cost is the annual costs which are proportional to the generating capacity divided by the power or kilowatts. This method of analysis is applicable to the majority of hydroelectric developments. The nature of a hydroelectric station is such that the factors that fix the cost of power are those which give an average cost over a period of years.

The discussion in the paper is divided into 3 sections. The first section is a brief outline of the method used in segregating system power costs and the development of the fundamental cost items. The second section has to do with the segregation of the power costs of hydroelectric stations into their component parts; the methods of developing the components for different classes of hydroelectric stations are outlined. In the last section the peculiarities of hydro power are given and the method of determining an average cost of power for a hydroelectric unit or system is outlined. (A.I.E.E. paper No. 32-112)

### The Reading Company's Philadelphia Suburban Electrification

By
G. I. Wright[4]

THE ELECTRIFICATION of the Reading suburban service in the vicinity of Philadelphia was first placed in operation July 26, 1931. The lines now under electrical operation include 65 route miles and 157 track miles, which will be increased by January 1, 1933, to 87 route miles and 203 track miles. These lines consist of 6 branches and cover all the suburban territory north of Philadelphia, between the Schuylkill and Delaware rivers.

Severe competition from automobiles, buses, a new subway, and the Pennsylvania Railroad's electrified lines had resulted in serious loss of traffic and revenue to the railroad. The Reading Company was faced with the alternative of impairing the existing steam operation to reduce costs, or providing a modern superior electrified service. The latter policy was decided upon and electric operation has now been in effect over a year. In spite of a 20 per cent speeding up of schedules and an increase in trains and train miles of approximately 100 per cent, the cost of operation is found to be substantially lower than for the service by steam in the same territory. The improved schedules combined with greater cleanliness and more attractive equipment have changed a steady loss in traffic into an appreciable increase. As a result, the railroad management recently authorized the electrification of the suburban service on its Norristown branch from Philadelphia to Norristown.

The present paper describes the electrification, giving details of power supply, substations, catenary structures, signal bridges, transmission lines, and catenary system, and rail return system. Considerable information is given also on the multiple unit cars, together with motors and control. Interchangeability of apparatus was given special consideration during design, and many special features have been incorporated. (A.I.E.E. paper No. 32-109)

## Electrical Operation on the Cascade Division of the Great Northern Railway

By
J. B. Cox[5]

ELECTRIFICATION of the Great Northern Railway's main line between Skykomish and Wenatchee, 73 route miles, was carried out in conjunction with the building of a new tunnel 7.79 miles long, and the relocation of approximately 17 route miles of troublesome track and other minor improvements, aggregating an expenditure of approximately $25,500,000. Although all of these improvements were placed in operation at about the same time, making a direct comparison of operating expenses difficult, analyses which give a reliable comparison between the cost of steam and electric operation over this part of the system have been made.

Operating difficulties with this recent electrification, especially those occurring shortly after the equipment was placed in service early in 1929, are described in this paper. Some of these difficulties were due to the condensation of moisture caused by the sharp changes in air temperature at the upper end of the tunnel and toward which the draft of air flowed. Other changes in the locomotives and control were found desirable and are described.

Segregated operating costs with steam and electric operation are presented, and show that although the route miles with the present electrified section are only 8.8 per cent less than the route miles with the previous steam operated section, the total operating costs are reduced 57.3 per cent. Costs of the electrification also are presented. (A.I.E.E. paper No. 32-110)

## Theory of the 3-Wire D-C. Generator With 2-Phase Static Balancer

By
E. G. Cullwick[6]

AN ANALYSIS of the theory of the 3-wire d-c. generator using a 2-phase static balancer is presented in this paper with the particular object of explaining the very large unsymmetrical magnetizing current peaks which occur in the balancer windings. These peaks are evidence of unsymmetrical flux variation attaining high values of flux density; and as their value may be equal to, or greater than, the total unbalanced current in the neutral wire of the system, they have a pronounced effect upon the r.m.s. value of the currents, and therefore upon the heating, in the balancer phases. They also cause marked pulsations in the terminal voltages of the machine.

These magnetizing current peaks are out of all proportion to the actual magnetic unbalance of the 2 phases on the balancer core; and the mathematical development shows that they are cumulative phenomena, analogous in a general way to the cumulative growth of field current in a shunt generator, and depending for their initiation upon only a very small magnetic unbalance of the balancer phases, and upon a normal maximum flux density which lies above the perfectly straight portion of the magnetization curve for the balancer core.

An expression for the e.m.f. induced in the balancer phases by the alternating flux in the core is obtained. From this are analyzed the conditions governing the cumulative growth of the current peaks until a steady value is reached. It is found that any unbalance of the resistance of the balancer phases has a marked effect upon the phenomena, it being possible by the introduction of a suitable unbalance to cause the peaks to reverse. If the resistances of the 2 phases are kept equal, it is found that the value of the current peaks decreases with the increase in the resistance of the balancer windings.

These theoretical conclusions are verified by oscillograms, which, taken on an actual machine, clearly show the nature of the phenomena and their variation with the operating conditions of the machine. (A.I.E.E. paper No. 32-111)

## Metering of Symmetrical Components

By
R. G. Shuck[7]

CONTENTS of previous publications on metering of symmetrical components have been confined to the components of current and voltage in 3-phase 3-wire systems. This paper discusses the method of metering the positive and negative sequence power and energy in 3-phase 3-wire systems, and positive, negative, and zero sequence power and energy in 3-phase 4-wire systems. Networks are described which make it possible to meter these components simultaneously and separately. Tables are included showing the location and number of instrument transformers required for each network. Equations involving the design of the impedances of the metering systems are given.

In discussing the various metering systems, the possibility is suggested of metering large blocks of power at the alternator terminals with 1 wattmeter, a positive sequence network, 2 potential transformers, and 2 current transformers, used to replace 3 wattmeters, 3 current transformers, and 3 potential transformers. Also it is suggested that in relay and control equipment the components of power be utilized as well as the components of current and voltage. Where definiteness of action depends upon the amount of voltage available at the relay, positive and negative sequence components of power might be utilized in the relay. One relay using the balanced components of current and voltage will function regardless of which phase is short circuited.

A preliminary design of a complete set of network impedances necessary for simultaneous metering of positive and negative sequence power reveals that the equipment could be placed in a box having dimensions of less than 6x6x6 in. (For presentation only; not scheduled for publication by the Institute.)

## Shaping of Magnetization Curves and the Zero Error Current Transformer

By
A. C. Schwager[8]
V. A. Treat[8]

NONE of the methods previously available to improve transformers is capable of producing an important requirement of the power industry; namely, the high accuracy, high voltage, low ratio, bushing type current transformer operated at a high secondary burden. However, in analogy with the molecular theories of magnetization, a method of shaping magnetization curves has been advanced for securing constant permeability. Tests prove this method to be very effective and to result in a permeability which remains constant within fractions of one per cent over a wide range of induction.

The method has been applied to the bushing or through type current transformer so desirable for the metering of high voltage transmission lines. For this type of transformer the exciting current of the core in the low flux density range of its normal operation has a

---

5. General Electric Company, Erie, Pa.
6. University of British Columbia, Vancouver, B. C.
7. University of Washington, Seattle.
8. Pacific Electric Mfg. Corporation, San Francisco, Calif.

nonlinear characteristic. However, a much smaller core of varied cross-section, working at a higher flux density, can be made to have an exciting current characteristic of almost exactly the inverse curvature and similar value to that of the current transformer core.

If a reactor with such a core be connected in parallel with a current transformer secondary, the total exciting current of the combination can be brought to an almost exact linear relation with the secondary voltage or current for a considerable range of values. This linearity produces a like relation as to primary and secondary currents. The loss of secondary current due to the parallel reactor is restored by reducing the number of secondary turns to bring the transformer to a desired ratio, and the phase angle discrepancy is corrected by neutralizing the major part of the exciting current by the reactive current of a parallel capacitor. A parallel resistor has a similar effect but the sensitivity of the transformer to burden variations is increased.

Current transformers with this auxiliary equipment (transformer compensator) are adjusted for a fairly large burden, such as 50 voltamperes and 0.50 power factor. A variable loading burden (burden compensator) is placed in the secondary circuit so that a considerable range of external burden is possible without affecting the calibration curve of the transformer.

A 115-kv. bushing type transformer with a silicon-iron core when thus equipped will give characteristic curves between 0.5 and 5 amperes secondary current not exceeding variations of 0.001 in ratio correction factor and 10 min. of phase angle. Greater accuracies than this are possible if required commercially.

High precision wound type current transformers also may be secured by this method at no substantial increase in cost or complication of construction. In the same manner zero error potential transformers and watt-hour meters, relays with prescribed characteristics and linear electric circuits including ferro-magnetic cores, are easily produced. **(A.I.E.E paper No. 32-116)**

## Factory Assemblies in Substation Design

By
M. H. Hobbs[9]

DESIGNS and factory procedure for factory assemblies of medium voltage substations which may be applied to either network or radial distribution systems are described in this paper. These substations may be divided roughly into 2 principal classes, those for serving large individual power consumers and those for general distribution to a community of varied customers. In the latter class may be included also substations in very large industrial plants and steel mills having their own generating and transmission systems.

For so-called customer substations of the indoor type, the special requirements are usually limited space, low cost, safety, and simplicity. Metalclad switchgear offers an ideal factory assembly for the high voltage side of such an installation, occupying as it does the minimum floor space both for installation and for operating aisles. From the low voltage side of the transformers a metal enclosed bus run is desirable, terminating in a metal enclosed structure with transformer and feeder air circuit breakers of either the draw-out type or the fixed type. In addition to the metalclad construction, truck type and cubicles are available in factory assembled construction. Customers' outdoor substations, comprising mainly the high voltage switchgear and transformers, also are available in this construction.

Substations for general distribution differ from so-called customer's substations largely in number of circuits, complexity of bus arrangement, and amount of meter and relay equipment used; otherwise similar apparatus may be used for both applications. Space may be at a premium on account of the larger amount of equipment to be accommodated, and in any case it is desirable of course that ground space cost be kept as low as possible.

It is in the wholly outdoor form of substation that the greatest saving from the use of factory assemblies can be effected, since a further saving comes from the elimination of the building. This applies whether the station is for a network or radial system. Cost analyses of factory assembled substation layouts show surprising over-all economy. **(For presentation only; not scheduled for publication by the Institute.)**

## High Voltage Oil Circuit Breakers

By
R. E. Rowley[10]

MECHANICAL maintenance of high voltage circuit breakers is of considerable importance to the successful operation of power systems. Experience obtained over a number of years has proved that in many ways existing equipment may be modernized and betterments provided by the operating engineer.

Some of the problems which have been encountered in maintaining and rebuilding high voltage oil circuit breakers in connection with a modern and fast growing system are indicated in this paper. It has been found that high voltage circuit breaker maintenance may be improved materially with the use of available apparatus such as the tuning fork and equipment for securing travel-time curves. Information obtained from such studies automatically will indicate whether improvements to the switchgear are necessary.

In the paper, details of the changes made to existing equipment are discussed; these include improvements in the solenoid, safety, and venting, and various other mechanical changes to give greater current carrying and interrupting capacities. The economy of rebuilding obsolete switches has been proved. In many cases, the rebuilding of switches has cost considerably less than new switches, and subsequent performance has been quite satisfactory, as all operations have compared favorably with those of newer equipment. **(For presentation only; not scheduled for publication by the Institute.)**

## Corona Loss Measurements for the Design of Transmission Lines to Operate Between 220 Kv. and 330 Kv.

By
J. S. Carroll[11]
Bradley Cozzens[10]

DURING the summer and fall of 1931, measurements at the Harris J. Ryan Laboratory, Stanford University, Calif., extended the range of corona loss data for conductor sizes beyond those investigated during 1930. In these latter tests the 3 conductor specimens studied were a 1.125-in. hollow copper cable, a 1.49-in. hollow copper cable, and a 2.0-in. hollow aluminum cable. The losses were measured on a 3-phase line 700 ft. long. Voltages as high as 600 kv. between lines were used. The conclusions obtained in these tests are summarized as follows:

1. There are throughout variations in corona loss that result from causes at present unknown. These variations are of sufficient magnitude to be considered in the design of transmission lines and should be remembered when studying corona loss data.
2. Further evidence proves that the die, grease, and other foreign matter existing on cables as received from the manufacturers greatly increase the corona loss, and that this loss can be partially eliminated by washing the cable with a solvent soap solution and thoroughly rinsing in water.
3. The cleaning of the cable surface by scratch brushing only slightly lowers the corona loss below that which exists on a new cable properly washed.
4. The polishing of a cable surface by buffing temporarily decreases the loss on the cable below that which exists on a new cable properly washed.
5. Dragging a clean cable a distance of $^1/_2$ mile increases the loss on the cable above that which is found on a washed cable, but the loss is less for this condition than for the new, unwashed cable as received from the factory.
6. The surface of clean washed cables that have been subsequently dragged ages rapidly, so that with a year of weathering the loss is practically the same as found on a new, washed, undamaged cable.

---

[9] Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.

[10] Department of Water & Power, City of Los Angeles, Calif.

[11] Stanford University, Calif.

7. The surface produced by buffing ages rapidly, and as observed over one week's time showed a great variation in loss which was not regular but at times approached the loss value as found for the new, washed cable.

8. The variation in corona loss as found on new, washed cables shows that the voltage shift for the same power loss on cables of different sizes is practically proportional to $r \log S/r$, which is the factor in $E_0$ which is varied by dimensions. ($E_0$ is the disruptive voltage, $r$ the radius of the conductor, and $S$ the spacing.)

9. Insulator loss if not considered may introduce an appreciable error in corona loss measurements at high voltages. The loss can be partially eliminated by properly shielding the insulator strings.

10. A completely transposed line 1,050 ft. long showed the same corona loss as the same length of line untransposed. A horizontally spaced line showed a slightly higher loss than the same length of line with the equivalent triangular spacing.

In addition to the description and discussion of results of these tests, the paper includes a description of the modifications in the high voltage wattmeter for these measurements. (A.I.E.E. paper No. 32-113)

## The Triple-Harmonic Circuit in 3-Phase Power Systems

By
T. H. Morgan[12]
C. A. Bairos[11]
G. S. Kimball[11]

THE IMPORTANCE of triple-harmonic voltages and currents in electrical power systems is generally recognized by engineers associated with the power and telephone industries. It is desirable to have some convenient method of representation and calculation of the triple-frequency effects in 3-phase power systems.

The path of the third-harmonic current is different from that of the fundamental current and for this reason the circuit can be considered as separate and distinct. The characteristics of the triple-frequency circuit as determined by laboratory experiment are given in this paper, and methods of measurement of the required quantities for accurate solution of the triple-frequency circuit are described.

The results of an experimental investigation of the equivalent triple-frequency circuit as proposed by H. S. Osborne in 1915 are set forth. A typical simple 3-phase power network has been set up and the measured currents compared with computed values. Oscillograms are presented of voltages and currents with typical transformer connections demonstrating the principles of operation of the circuit both for normal and abnormal excitation conditions. The effects of various types of connected loads are discussed with particular attention to the condition of triple-frequency resonance. It is shown that triple-frequency resonance occurs when the external capacitive reactance of the circuit is equal to the triple-frequency no-load impedance of the transformer. Resonance produces large triple-frequency currents and serious distortion of the line-to-neutral voltage of the system. **(For presentation only; not scheduled for publication by the Institute.)**

## The Radio Plant of R.C.A. Communications, Inc.

By
H. H. Beverage[13]
C. W. Hansell[13]
H. O. Peterson[13]

THE Radio Corporation of America, through its subsidiary, R.C.A. Communications, Inc., operates a world-wide radio communication network between the United States and some 40 foreign countries. The major terminals of this world system are located at New York and San Francisco, with smaller centers at Honolulu, Manila, and Havana. The associated receiving and transmitting stations are located outside of these cities at various convenient distances.

A system has been worked out whereby all operations are concentrated in a central office at each of these terminals, thereby eliminating delays and errors inherent in the previous system of sending traffic over telegraph wires between the central office and the radio station. The development of short wave transmission also has greatly facilitated transoceanic radio service. Due to the great number of stations operating on both long and short waves, it is necessary to maintain means for monitoring the transmitters and for measuring the radiated frequencies with great accuracy. On the short waves, the frequency must be maintained within 0.05 per cent for old equipment and within 0.02 per cent for new equipment.

Starting with 6 circuits in 1920, these have expanded to a total of 54 circuits in 1932. During this period the number of messages also has increased greatly. Equipment necessary for this service of transmitting telegraph signals by modulation of radio frequency power is described in detail in this paper. Central office equipment, transmitting equipment for both long waves and short waves, receiving equipment, and frequency measurements are covered. (A.I.E.E. paper No. 32-115)

## Radiotelephone Experiments Over Short Distances

By
C. H. McLean[14]

RADIO in communication practise generally is associated with long distances over which physical plant is economically impossible. There are very few communities of appreciable size on the North American continent that are not linked up with the various telephone networks. Exceptions are to be found in British Columbia and Alaska where the territory intervening between the isolated settlements and populated areas is of such rugged nature as to render impossible from the standpoint of economy, the use of the usual telephone facilities.

Radio already successful over longer distance was adopted as the medium for providing telephone communication to the telephonically isolated centers lying within 600 miles north of Vancouver, B. C.

Radio experimental work on frequencies between 1,500 and 6,000 kc. has been in progress during the last 3 years employing equipment primarily designed for air transport communication. The radio transmitter has an unmodulated carrier rating of 400 watts, employs quartz crystal control of frequency and is capable of complete modulation. The receiver is of special design and includes the important feature of automatic gain control.

In the early experimental work a boat completely equipped with the necessary power plant and 400-watt equipment, cruised up the coast as far as southern Alaska, and tests were conducted between the boat and a land station located at Lulu Island near Vancouver. Considerable data relative to field strengths, fading and skip effect of various frequencies were collected for various points within a radius of 600 miles from the shore station. Further work included additional experimental installations at Campbell River, Ocean Falls, and Prince Rupert. Campbell River, the most northerly point connected by telephone lines, is the connecting point for the Ocean Falls (210 miles) and Prince Rupert (400 miles) radio links. Commercial operation over the last $1^1/_2$ years has proved the practicability of this form of communication, and it is believed that with the improved equipment now available, the expansion of this service upon a more permanent basis is justified. (A.I.E.E. paper No. 32-114)

# Middle Eastern District to Meet at Baltimore

THE next meeting of the Middle Eastern District will be held at Baltimore, Md., October 10–14, 1932, with headquarters in the Lord Baltimore Hotel. A preview of the attractions which the Baltimore meeting will offer is given by A. L. Penniman, Jr., of the Baltimore Section as follows:

"The technical program will be of unusual interest, including a joint session with the committee on insulation of the National Research Council at which papers will be presented covering the latest discoveries in dielectrics and the most recent developments of cable research. There will be papers on telephone cable covering the recent advances in the design and manufacture of pulp [illegible]ed cable, as well as on the use of cable [illegible]ephone distribution purposes, which [illegible] be supplemented by inspecting the [illegible] Breeze works of the Western Electric [illegible]any, a modern telephone cable manu[illegible]ring plant. The electric power session will be of particular interest as it will cover the economic aspects of water power, the design and construction of the Safe Harbor hydroelectric plant with particular reference to the hydraulic turbines which were especially designed for sustained efficiencies under variable head and at partial loads. There will be papers covering the 80-mile long, 230-kv. transmission line from Safe Harbor to Baltimore, the step-down station and the utilization of hydroelectric power in Baltimore with an inspection trip to the dam site where the Kaplan turbines, step-up station, transmission line river crossing and other interesting details may be inspected.

"Baltimore has much to offer visitors, not only in the development of industry but in the cultivation of art, literature, science, and engineering. In a little more than 2 centuries she has become one of the greatest manufacturing ports along our eastern seaboard but still retains the charm and culture which, with the aid of an ideal climate, developed from the inception of the province and produced such literary geniuses as Edgar Allen Poe, Sidney Lanier, Francis Scott Key, and James Ryder Randall of 'Maryland My Maryland' fame.

"The same courage and foresight which prompted Maryland to be the only one of the original 13 states to go through nearly the entire period of the Revolution as a separate and distinct sovereignty, then give to the federal government the territory now the District of Columbia and have its general assembly at Annapolis provide the necessary money for the completion of the federal buildings so that Congress might have a meeting place in the federal capital, also prompted the formation of the first gas-light company in 1816, and some 12 years later the starting of the first steam railroad in America and thereby laid the foundation of the fortune which was some half-century later to furnish the funds for the Johns Hopkins University, making possible incalculable contributions to science by such men as Rowland, Remsen, and Wood, and providing a fertile field for the rapid growth of the engineering school during its 20 years of existence under the able guidance of Whitehead and Kouwenhoven. Peale's Museum where the first gas lighting was installed and the Mt. Clare station from which the Baltimore and Ohio Railroad dispatched its first train and which on that historic day in May nearly 90 years ago received the first telegraphic communication in the world are both places of more than usual interest, as are the Flag House, where Mary Pickersgill made the American flag which waving over Fort McHenry inspired Key to write our national anthem, and the home of Charles Carroll, signer of the Declaration of Independence, which, splendidly preserved, is now a part of the Hopkins building group.

"A sightseeing trip and tea for the ladies will take them to Annapolis, the capital of the State for nearly 300 years, where General Washington surrendered his commission as commander-in-chief of the Continental Army, still retains the delightful atmosphere of colonial days. The old senate room has been preserved as it was when the continental congress met there while Annapolis was the nation's capital. King William's School founded in 1696, now St. John's College, is the third oldest institution of learning in the country, and was one of the first free schools in the colonies. Here is located the United States Naval Academy, in the crypt of whose chapel lies the remains of John Paul Jones, and here also is the flag which has given the Navy its watchword, 'Don't give up the ship.'

"The Baltimore Section urges you to come to the meeting in October with the assurance that you will find an unbounded hospitality."

**One of the many points of interest which may be visited during the A.I.E.E. Middle Eastern District meeting, Baltimore, Md., October 10–13, 1932, is shown above. It is Mt. Vernon Place, looking north, and contains the first monument erected to the memory of George Washington. It was a gift from the French Republic**

# Last Call for the Pacific Coast Convention

INTEREST now is centered upon the next major event of the Institute's program; namely, the Pacific Coast convention to be held this year at Vancouver, B. C., August 30 to September 2, 1932. Details of this convention were published in ELECTRICAL ENGINEERING for July 1932, p. 518–9, and abstracts of all technical papers which at the time of publication of this issue were definitely scheduled, are given in this issue, p. 583–6.

Combined with the unusual entertainment features available in the region in such abundance and variety as to appeal to the "vacation" ideas of every man, woman, and child, the technical program and more formal features of the convention should attract a large registration.

### CHANGES MADE IN FEES FOR REGISTRATION AND ENTERTAINMENT

Of no little interest to those planning to attend the convention are the changes which have been made in fees. There will be no registration fee for the convention. Entertainment tickets, however, which cover the dance after the president's reception on August 30, the boat trip on August 31, the dinner on the boat, the banquet on September 1, and, in the case of the women, the bridge tea on September 2, will be available at the following rates:

| | |
|---|---|
| Members and men guests | $6.00 per strip |
| Women | 5.00 per strip |
| Students | 2.50 per strip |

Tickets for separate items will be available for men, women, and students.

This new information regarding fees supersedes that given in ELECTRICAL ENGINEERING for July 1932, p. 518.

### EXCHANGE RATES FAVOR UNITED STATES CURRENCY

Consideration should be given by all persons from the United States attending the convention to the present rate of exchange between United States and Canadian currency. Persons from the United States may effect a net reduction of 15 per cent in the effective amount of expenditures on the Canadian side of the border by making an exchange from United States into Canadian currency at an established banking institution covering expenditures which will likely be made in Canada. United States money presented in Canada for payment of bills is accepted dollar for dollar without reference to the exchange rate which now favors United States credit.

# A.I.E.E. Directors Meet During Cleveland Convention

The regular meeting of the board of directors of the American Institute of Electrical Engineers was held at the Hotel Cleveland, Cleveland, Ohio, on Wednesday, June 22, 1932, during the annual summer convention of the Institute.

Present were: *President*—C. E. Skinner, East Pittsburgh, Pa. *Past-president*—W. S. Lee, Charlotte, N. C. *Vice-presidents*—H. V. Carpenter, Pullman, Wash.; H. P. Charlesworth, New York, N. Y.; L. B. Chubbuck, Hamilton, Ont.; W. E. Freeman, Lexington, Ky.; W. B. Kouwenhoven, Baltimore, Md.; T. N. Lacy, Detroit, Mich.; I. E. Moultrop, Boston, Mass.; G. C. Shaad, Lawrence, Kans. *Directors*—A. E. Bettis, Kansas City, Mo.; A. B. Cooper, Toronto, Ont.; B. D. Hull, Dallas, Tex.; J. Allen Johnson, Buffalo, N. Y.; A. E. Knowlton, New York, N. Y.; A. M. MacCutcheon, Cleveland, Ohio; F. W. Peek, Jr., Pittsfield, Mass.; C. E. Stephens, New York, N. Y. *National treasurer*—W. I. Slichter, New York, N. Y. *Acting national secretary*—H. H. Henline, New York, N. Y.

Present by invitation were: *Past-presidents*—Paul M. Lincoln, Ithaca, N. Y.; Charles F. Scott, New Haven, Conn. *Officers-elect*—K. A. Auty, Chicago, Ill.; G. A. Kositzky, Cleveland, Ohio; A. H. Lovell, Ann Arbor, Mich.; E. B. Meyer, Newark, N. J.; A. C. Stevens, Schenectady, N. Y.

The minutes of the directors' meeting of May 20, 1932, were approved.

A report of a meeting of the board of examiners held June 15, 1932, was presented and approved. Upon the recommendation of that board, the following actions were taken upon pending applications: 3 applicants were transferred to the grade of Fellow; 7 applicants were elected to the grade of Member and 30 were transferred to the grade of Member; 62 Associates were elected; 54 Students were enrolled.

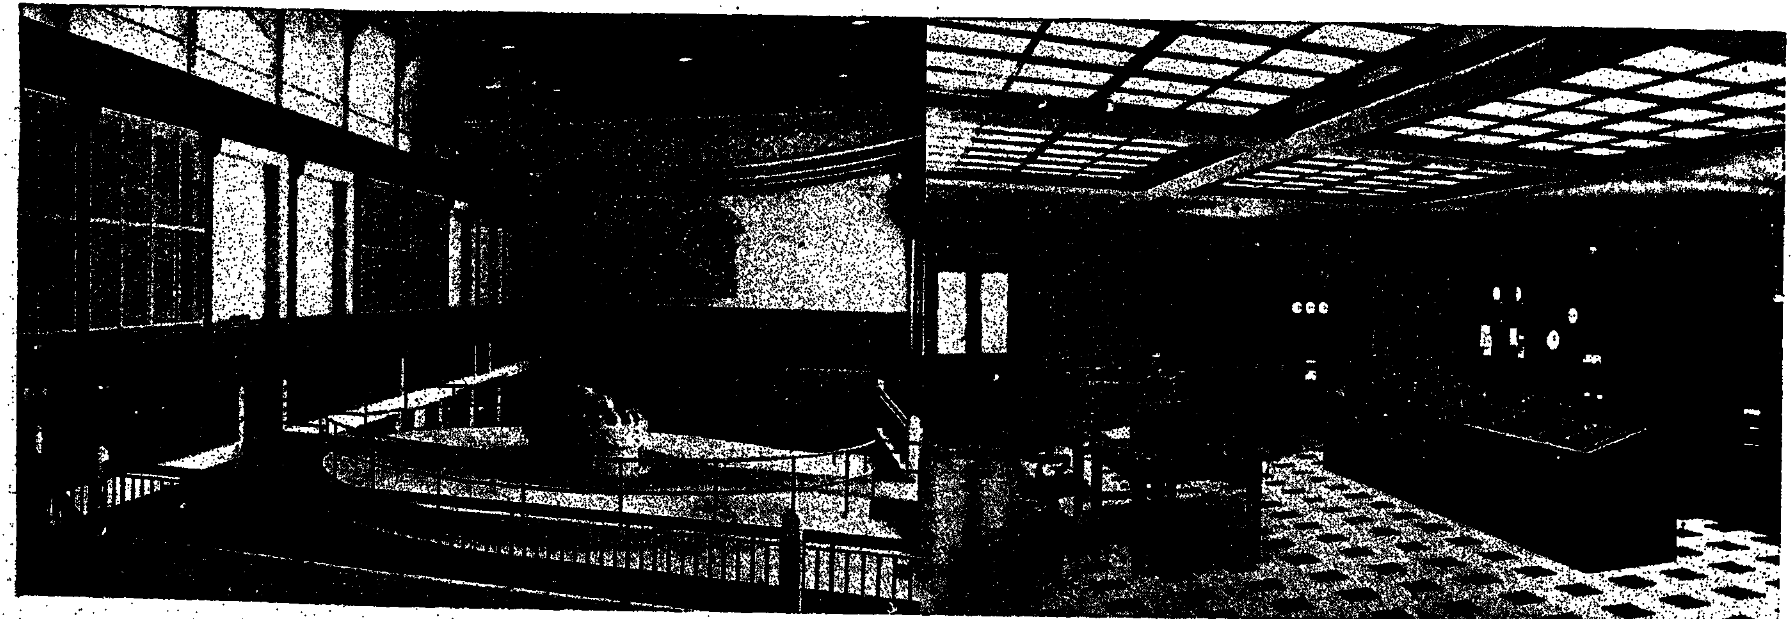
Approval by the finance committee, for payment of monthly bills amounting to $42,808.20, was ratified.

For the purpose of stimulating more prompt payment of membership dues by the mailing of dues notices at shorter intervals, after May 1, 1933, Section 18 of the By-Laws was amended by replacing the second and third sentences with the following: "On August first, November first, and February first, notices shall be sent to those remaining in arrears, the February first notice to be accompanied by a copy of this section of the By-Laws."

Resolutions were adopted, expressing the directors' appreciation of the services of the Cleveland convention committee and its subcommittees.

Various recommendations adopted at the conference of officers, delegates, and members on June 20 and 21 were considered and referred to appropriate committees already in existence or to be appointed; and approval was given to a recommendation that the Districts be requested, when planning Districts meetings, to consider the formation in each case of a subcommittee of the general convention committee to coordinate all phases of student participation in the convention activities, and to schedule a student session which will not conflict with any of the technical sessions, inspection trips, or other events of the convention; or in lieu thereof, to consider scheduling one or more student papers in the programs of the main technical sessions.

Other matters were discussed, reference to which may be found in this or future issues of ELECTRICAL ENGINEERING.



Generator room (left) and control room (right) in the Ruskin power plant of the British Columbia Power Corporation, Ltd., near Vancouver, B. C. Inspection of this plant will be made during the A.I.E.E. Pacific Coast convention, August 30–September 2, 1932. The generator, rated at 47,000 hp., is of the "umbrella" type

## Convention Sports Trophy Information Completed

Supplementary information and a correction are presented here to bring correctly up to date the listing of winners of A.I.E.E. summer convention sports trophies given on p. 521 of ELECTRICAL ENGINEERING for July 1932. The name of L. F. Deming (A'11) of Philadelphia, Pa., permanent winner of the first Mershon golf trophy was misspelled in last month's report.

Concerning the Mershon tennis trophy it should be recorded that the first trophy was offered for competition at the 1923 summer convention held at Swampscott, Mass., and was won in that year by J. P. Nikonow (M'18) of New York, N. Y. In 1925 the cup was won permanently by G. A. Sawin (M'13) East Pittsburgh, Pa., who also had won the tennis tournament of 1924. In 1926 Past-President Ralph D. Mershon made available a second tennis trophy which was won in that year by L. B. Chubbuck (M'26) of Hamilton, Ontario, Canada.

These additional data together with a correction in the present address of Mr. A. J. Gowan make the following list of Mershon tennis trophy winners correct according to present Institute records:

**First Trophy**

1923—J. P. Nikonow, New York, N. Y.
1924—G. A. Sawin, East Pittsburgh, Pa.
1925—G. A. Sawin, East Pittsburgh, Pa.

**Second Trophy**

1926—L. B. Chubbuck, Hamilton, Ontario, Canada.
1927—G. A. Sawin (M'13) East Pittsburgh, Pa.
1928—P. H. Hatch (M'29) Stamford, Conn.
1929—A. J. Gowan (A'23) Rock Island, Ill.
1930—E. F. Lopez (M'18) Mexico City, Mex.
1931—J. K. Peck (A'27) New York, N. Y.
1932—R. A. Monroe (A'30) Pittsburgh, Pa.

## American Tentative Standard for Engineering Abbreviations Adopted

BRINGING to a close a preliminary period of several years of effort, the sectional committee on scientific and engineering symbols and abbreviations of the American Standards Association recently made a final report to that Association embracing an American Tentative Standard specifying and governing the use of abbreviations for scientific and engineering terms. This tentative standard is strictly an editorial specification listing more than 200 abbreviations considered as acceptable for use in the preparation of technical manuscripts, and setting forth 8 practical rules governing the use of such abbreviations in text matter. In this initial list of abbreviations the committee has included only the terms in most common use.

The tentative standard as it now stands, with its list of abbreviations and its rules governing their use, has been accorded official approval by the A.I.E.E. and also by the American Association for the Advancement of Science, the American Society of Civil Engineers, the Society for the Promotion of Engineering Education, and The American Society of Mechanical Engineers. It is expected that these sponsoring organizations will bring into conformity with the standard list the abbreviations now used in their respective publications, and from time to time will contribute to the extension of the standard list by the addition of further mutually agreeable abbreviations. In sanctioning these abbreviations, each society authorized those falling within the sphere of its professional activity, recognizing at the same time the other abbreviations as authorized by the other organizations. Controversial abbreviations were omitted from the list subject to subsequent settlement.

The subcommittee of the sectional committee that carried on the research in abbreviations for scientific and engineering terms includes G. F. Bateman, professor of mechanical engineering, Cooper Union, New York, N. Y.; S. McK. Gray, Electrical Testing Laboratories, New York, N. Y.; W. T. Magruder, professor of mechanical engineering, The Ohio State University, Columbus, Ohio; Dr. W. N. P. Reed, assistant editor, Engineering and Mining Journal, McGraw-Hill Publishing Company, Inc., New York, N. Y.; H. E. Ruggles, Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.; working under the chairmanship of G. A. Stetson, editor, The American Society of Mechanical Engineers, New York, N. Y. Officers of the A.S.A. sectional committee on scientific and engineering symbols and abbreviations include J. F. Meyer, Bureau of Standards, Washington, D. C., chairman; S. A. Moss, General Electric Company, West Lynn, Mass., vice-chairman; P. S. Millar, Electrical Testing Laboratories, New York, N. Y., secretary; and S. McK. Gray, assistant secretary. The executive committee of the A.S.A. sectional committee includes J. F. Meyer as chairman and S. A. Moss as vice-chairman; also Dr. A. E. Kennelly, Harvard University, Cambridge, Mass., representing the American Association for the Advancement of Science; H. N. Davis, Stevens Institute of Technology, Hoboken, N. J., representing The American Society of Mechanical Engineers; and C. M. Spofford, Boston, Mass., representing the American Society of Civil Engineers.

### RULES GIVEN

To clarify a necessary distinction, the committee has ruled that:

A symbol is a letter or sign used in a formula as a substitute for any numerical value. A shortened expression for a name or a unit is an abbreviation and *not* a symbol. Concerning the use of abbreviations, the committee's recommended standard specifies that:

1. Abbreviations should be used sparingly in text and with regard to the context and to the training of the reader. Terms denoting units of measurement should be abbreviated in the text only when preceded by the amounts indicated in numerals; thus "several inches," "one inch," "12 in." In tabular matter, specifications, maps, drawings, and texts for special purposes, the use of abbreviations should be governed only by the desirability of conserving space.

2. A sentence should not begin with a numeral followed by an abbreviation.

3. Short words such as ton, day, and mile should be spelled out.

4. Abbreviations should not be used where the meaning will not be clear. In case of doubt, spell out.

5. The use of conventional signs for abbreviations in text is not recommended; thus "per," not /; "lb." not #; "in.," not." Such signs may be used sparingly in tables and similar places for conserving space.

6. The committee indorses the movement which was begun by the international committee on weights and measures in omitting the period in abbreviations of metric units and further indorses the growing tendency toward the omission in abbreviations of other origin. In the interests of economy and the reduction of waste, the elimination of the period is recommended except where such an omission results in an English word. Exceptions to this practise will be found in a few mathematical and chemical terms, such as sin, tan, log, As, etc.

7. The letters of such abbreviations as A.I.E.E. should not be spaced (not A. I. E. E.).

8. The use in text of exponents for the abbreviations of square and cube and of the negative exponents for terms involving "per" is not recommended. The superior figures usually are not available on the keyboards of typesetting and linotype machines, and composition therefore is delayed; also there is the likelihood of confusion with footnote reference numbers. These shorter forms are permissible in tables and sometimes are difficult to avoid in text.

Principal changes that may be noted in the tentative standard list of abbreviations include the elimination of practically all periods from abbreviations, and shorter forms of some otherwise common abbreviations. As new material is set up for subsequent publication in ELECTRICAL ENGINEERING and other A.I.E.E. publications, such abbreviations as are used will be brought into conformity with the tentative standard list.

### PERMISSIBLE ABBREVIATIONS

In conformity with the A.S.A. tentative standard, the following partial list indicates the style of abbreviations recommended by the A.I.E.E. publication committee for use in Institute manuscripts and publications:

| | |
|---|---|
| Acre-foot | acre-ft |
| Alternating-current (as adjective only) | a-c |
| Ampere | amp |
| Ampere-hour | amp-hr |
| Antilogarithm | antilog |
| Average | avg |
| Barrel | bbl |
| Baumé | Bé |
| British thermal unit | Btu |
| Calory | cal |
| Candlepower | cp |
| Centigram | cg |
| Centimeter | cm |
| Circular mils | cir mils |
| Circular-mil (adjective) | cir-mil |
| Cologarithm | colog |
| Cord | cd |
| Cosecant | csc |

# Summarized Review of Some Cleveland Convention Discussions

PRINCIPAL discussions of the Cleveland convention papers are summarized herewith. The papers to which these discussions refer were abstracted in ELECTRICAL ENGINEERING for June 1932, p. 405–13.

Only discussion submitted in writing in accordance with governing A.I.E.E. rules is summarized. Complete discussion, together with all approved papers, will be published in the TRANSACTIONS.

### THE ENGINEERING SUBJECTS IN THE COLLEGE PROGRAM

S. M. Dean (Detroit, Mich.) discussed this subject with the view that an increasingly large proportion of engineers eventually get into administrative positions. He agrees, however, than any electrical engineer must have a basic training in the fundamental concepts. Referring to Table I of the paper, he would include in the first prescribed group the fundamental courses as well as transmission and distribution; also electronics. He also suggested that a rather wide range of the more specialized subjects should be offered as electives to determine the "natural bent" of the student and to show him into what the various branches of the electrical engineering profession will lead him. The necessity for a successful administrative engineer to take a broad view of any situation, and his ability to set forth his ideas in a logical and convincing manner, were emphasized as important characteristics. He suggested, too, that the story of obstacles surmounted and of the men who contributed to this successful development of the various steps both from a strictly engineering angle as well as from the commercial point of view, would serve as a helpful background.

R. E. Hellmund (East Pittsburgh, Pa.) called attention to the lack of training in the mechanical features of machine design and engineering materials as shown in Table II of the paper. He stressed the point that all component parts of electrical machines and apparatus present mechanical problems and that the greater part of the work of electrical design engineers has to do with the mechanical phase. He believes that some of the time now devoted to heat, power, and hydraulics should be devoted to mechanical design and engineering materials; at least, he believes good courses on these subjects should be available to those wishing to go into design work.

A. E. Knowlton (New York, N. Y.) in his discussion of this subject urged generous support of Dean Lovell's plea that the electrotechnical content of the curricula be surveyed, but at the same time he warned against placing too much emphasis on statistical data. With regard to reversion to fundamentals and the elimination of specialization, two solutions were offered. One of these suggested a review of the content of fundamentals with a test of every item for its broad applicability over the whole range of energy magnitudes and diversified applications; those phenomena and principles having the widest range of adaptability to electrical activities would appear most entitled to be ranked as fundamentals. The other solution suggested that more stress be placed upon functional significance of electrical phenomena and the physical equipment devised to exploit them. The "horizontal" character of such a set-up would give the subject matter a bearing upon every branch of the art involving an exercise of those functions.

Another discussion by D. C. Jackson, Jr. (Lawrence, Kansas) brought out recent changes made in the electrical engineering curricula of both the University of Kansas and Kansas State College. The former now has a greater number of hours given over to fundamental course in electrical engineering, while the latter has increased the number of hours for electronics, making it a required rather than an elective course. These changes tend to substantiate the trend indicated by Professor Lovell in his paper.

Another view of this subject from the point of industry was presented by W. W. Lewis (Schenectady, N. Y.), who explained that graduates ultimately were absorbed through 3 main channels: large manufacturing companies; large public utilities; and small manufacturing companies, public utilities, and industrial plants. The first 2 groups maintain more or less extensive training courses and require broad training in fundamentals; but the latter group requires in addition specialized training to fit the graduate for immediate usefulness. Since very few students know until just before graduation in which group they will be employed, Mr. Lewis believes that it is obviously necessary to give all students the broad fundamental courses plus a number of specialized courses. He agrees that the subject of electronics is becoming increasingly important and that practically all of the courses listed in Tables I and II of the paper were desirable, with the exception of those on surveying and foreign languages.

Still another view from industry was contributed by L. F. Morehouse (New York, N. Y.). He questioned whether all of the required work should not be given in truly fundamental courses in which the broad fundamentals would be illustrated from every phase of electrical engineering. If this should be impractical it was suggested that required courses other than those designated as "fundamental" should have a more general content and be more widely illustrative of modern electrical engineering in its broadest application.

L. W. W. Morrow (New York, N. Y.) ably discussed the subject of technical education, calling attention to the need for engineering courses to keep abreast of the rapidly changing art. An analysis of Table I of the paper quickly raised a number of pertinent questions which indicated the variation in hours devoted to fundamental courses, the lack of correlation between fundamental course hours and additional required or elective hours, the specialized courses consistently taught, and the lack of courses such as electrochemistry and electronics. Upon analysis, such data showed very vividly an antiquated, superficial, and cumbersome content for the technical engineering courses. The next step in this discussion, based upon Mr. Morrow's broad experience and extensive contacts, showed briefly but valuably what problems confront practising engineers of today. In conclusion, the following recommendations were made relative to the technical content of college courses: (1) Stick to theoretical principles and apply them to all current engineering applications; (2) eliminate the old, the standardized, and the obsolete principles and applications, and replace them with new and live theories and applications; and (3) do not specialize in terms of arbitrary and artificial field divisions of engineering, but require all students to take the same fundamental course with a few electives in specialized theory instead of practise.

A. E. Silver (New York, N. Y.) also discussed this subject, and was of the opinion that natural ability justifying a 4-year course should be devoted primarily to the laying of a foundation—learning the principles of accomplishment by effectively directing the forces at hand, acquiring the trait of making one's knowledge available and of value to others, and finding one's natural self—leaving specifications largely to graduate work and one's later initiative and experience.

### Educational Aspects of Engineering and Management

R. E. Hellmund (East Pittsburgh, Pa.) discussed this subject and emphasized particularly the point that enthusiasm over the fact that engineering education had turned out personnel suitable for industrial management, should in no way lead to a diminution of the technical engineering phase of the undergraduate program. It was pointed out that although only 25 per cent remain in technical work after the age of 40, the majority soon after leaving college are called upon to carry on technical engineering. He advocated that rather than change the undergraduate courses, managerial training should be given in the various postgraduate programs.

D. C. Jackson, Jr. (Lawrence, Kan.) also discussed this phase of the subject and it was his belief that engineering training would continue to be valuable for managerial duties in industries based upon engineering. With students, there might be a trend toward business courses, administration or management, but it appeared doubtful whether such courses of study could provide so satisfactory a training as do engineering courses.

Another discusser, E. E. Johnson (Schenectady, N. Y.), related a number of instances where men who have demonstrated a high order of technical leadership gradually came into positions of technical management. He did not feel that inclusion of a fundamental technical background in engineering curricula would detract from the field of management.

### Reliability and Economy in the Operation of Large Electric Systems

This subject was introduced very comprehensively by the presiding officer, F. H. Hollister (Chicago, Ill.), who told of the origin and objective of the symposium. He pointed out that each district had its own peculiar problems and that there were scarcely 2 alike. For example, Philadelphia with a major hydroelectric connection was contrasted to Chicago with no hydroelectric connection of any great importance. Each paper was believed to present a method of determining how each of the respective metropolitan systems with its particular characteristics is operated to secure maximum reliability and economy. In each instance, however, the goal is reached in a different manner by devious paths that rarely cross but it is believed that each system with its scheme of operation has ample backing and justification.

One of the interesting phases of a discussion by R. L. Thomas (Baltimore, Md.) related to the essentiality of accurately forecasting future loads under present economic conditions. It is his belief that under present conditions, any forecaster who predicts loads for even a year or 2 in advance, with an error of only 2 or 3 per cent, may consider himself fortunate.

J. R. Baker (Baltimore, Md.) in his discussion summarized indications in the papers which related to interconnections. Apparently they were not producing the widely connected geographical power scheme forecast by some of the early proponents. The true function of interconnection seemed to be of a supplementary nature, and the papers tended to show that the main reliance for power supply in any load area would continue to reside in power stations adjacent to the load.

Another discussion by C. M. Gilt (Brooklyn, N. Y.) considered 2 different methods of meeting the situation arising when it might become necessary to shut down a generating station completely. Costs for such systems at first might appear high, however, for the larger systems, the magnitude of such completely isolated stations is of the order of 500,000 kva., and makes use of the most economical size of units available.

Another part of a general discussion presented by J. R. Baker (Baltimore, Md.) referred to carrying out construction projects in advance of load requirements for reasons of reliability or economy in operation. He explained that such work had been confined chiefly to the replacement of obsolete and inadequate equipment. In general, for reasons of economy in operation the company was not committed to investments in advance of actual load requirements. The exception is in the case of such items as converting attended substations into the automatic type where definite labor savings can be predicted.

### The Coordination of Transformer Insulation With Line Insulation

R. N. Conwell (Newark, N. J.) cited objections to the fixing of transformer insulation at a definite arbitrary value and then relying upon the designer of a transmission line to coordinate with these values. Such a method, he explained, surely could not produce a well-balanced, satisfactory, economical, system design. The transmission designer is handicapped at the very

## The Engineer

HE IS THE master of the Laws of Nature. On a sound foundation of mathematics, science, and economics, he bends the materials and forces of Nature to his plan and rears the structure of civilization.

With vision, resourcefulness, and ingenuity, he labors to increase the comfort, wealth, and safety of his fellowmen.

He attacks his problems with the vision of the pioneer, the integrity of the scientist, the accuracy of the mathematician, the practicality of the business man, the resourcefulness of the inventor, and the courage of the conqueror.

He is the planner and builder. He builds his visions into enduring realities.

He is the pathfinder of civilization. He breaks down the barriers, bridges chasms, establishes communication, and straightens the way for commerce and human progress.

He is the protagonist of efficiency. He reduces the effort, eliminates waste, and increases production.

He is the creator of a Nation's wealth. He drains the swamps, reclaims the deserts, develops resources, and harnesses power. He builds the machinery of industry, the wheels of commerce, and the structure of business.

He is the great coordinator. He plans and directs the construction of projects representing the investment of millions of dollars and the labor of thousands of men.

He investigates with open mind, and gets the facts before he makes decisions. He plans with thoroughness and builds with fidelity.

To his rich heritage from the labors of past generations of engineers and scientists, he adds his contributions. He continues the work of forcing outward the challenging barriers that separate Man's efforts from the impossible.

By D. B. Steinman, President of the New York State Society of Professional Engineers, and Past-President of the American Association of Engineers. Reprinted from "The American Engineer" for February 1932.

start by the necessity of meeting limits established without regard to service conditions or local factors, such as the character of the terrain, lightning exposure, frequency of storms, or the position of the line with regard to storm paths. He suggests that a suitable committee canvass thoroughly a large number of operating companies to determine preferences in future insulation levels, and he believes that the methods employed for coordination should be the basis of determining transformer insulation requirements.

F. J. Vogel (Sharon, Pa.) also discussed this subject; it is his belief that the coordination of transformer insulation with the gap was of great value not only to operating engineers but to the manufacturers in providing a yardstick to measure the surge strength of station apparatus. He felt that the gap would be used merely as the level in the case of very low voltages, and that for this purpose, the table in the paper might be extended.

J. B. Hodtum (Pittsburgh, Pa.) discussed justification for the development of the coordinated distribution transformer. He explained that such a transformer had been developed and had been on the market now for 4 years. Impulse tests confirmed by 4 years of service have demonstrated that these transformers would flash over the bushings before the transformer itself would fail. Over 5,000 such transformers have been in service without a single failure having been reported.

Another discussion of this subject by J. K. Hodnette (Sharon, Pa.) pointed out that if the transformers were designed in the usual way with the high-voltage winding divided into 2 or more parts, the initial voltage stresses across the coils would be reduced materially as compared with the coordinated design. From this material reduction in stress it would appear that the shields were not essential for building a transformer with coordinated insulation.

### CHARACTERISTICS OF SURGE GENERATORS

C. L. Fortescue (East Pittsburgh, Pa.) discussed this subject and explained that the importance of the paper rested in the fact that the author had demonstrated that what might appear as extremely complicated circuits, could be represented with a close approximation by simple circuits. He believes that the author has shown the ease of predicting the actual wave under test conditions, thus permitting specifications for surge testing of apparatus without fear, provided surge measurements are properly carried out and calculations are made beforehand, to insure that the apparatus is receiving the proper test.

W. L. Lloyd, Jr. (Pittsfield, Mass.) believes this paper timely, well-written, and interesting, but he does not feel that the subject is particularly new. Reference was made to Mr. Peek's first lightning generator of 1913, and to the fact that the impulse voltages delivered by such a circuit have been subject to calculations.

### LOAD RATIO CONTROL CIRCUITS

F. L. Snyder (Sharon, Pa.) in his discussion of this subject pointed out that whether an air-gap should or should not be used in the core of the reactor depended upon the characteristics of the circuit desired. In any event he felt that the tap changer, the transformer, and the reactor must be insulated for the voltages which may be impressed upon them under both normal or abnormal conditions. Conceivably, a tap changing operation might take place at the instant of line short circuit.

A. Boyajian (Pittsfield, Mass.) in discussing this subject felt that usually attempts to limit voltage rise by saturation result in just the opposite effect. Noncritical expectations based on r.m.s. characteristics come to grief, and the very feature (saturation) depended upon for protection, stings and pierces the insulation of the circuit by needle-shaped voltage peaks. In terms of elementary sine wave concepts associated with linear circuits and without recourse to advanced mathematics, he analyzed the meaning of saturation phenomena in an a-c. circuit as understood physically.

H. O. Stephens (Pittsfield, Mass.) discussed this subject. He referred to tests which showed that when preventive reactors with closed magnetic circuits were used, decided peaks in the voltage waves across the reactors were obtained, the arcing on the contacts was severe, and the contact life unsatisfactory. However, with air core reactors, or with iron core reactors having suitable air-gaps in the core so as to obtain a substantially straight-line volt-ampere characteristic throughout the working range, the bad peaks in the voltage across the reactor were eliminated and the life of the contacts greatly increased.

### INFLUENCE OF BRUSH CONTACT DROP ON COMMUTATION

R. E. Hellmund (East Pittsburgh, Pa.) in discussion of this subject gave an interesting hypothesis of contact phenomena which, although not as yet checked with results of experimental data, seemed valid. It is his belief that contact phenomena may eventually be explained in a rather simple manner by assuming certain mechanical conditions in the contact areas, nothing but ohmic resistance in the materials proper, and other already well-known phenomena.

L. A. Heath (Long Island City, N. Y.) cited the existence of ever-changing conditions of contact between brush and commutator. He referred to brush sparking when a cold rotary or generator is started and immediately carries full load. During this initial period the slope of the brush contact curve indicates too great an interpole field strength, but after sparking ceases, the contact curve is quite normal. Inspection of the brush faces during this initial period indicates that the brushes have changed their seating from that taken at the last shut-down.

Another discussion by W. E. Stine (Cleveland, Ohio) explained that the authors' theory of sliding contact and data submitted was in very close conformity with a theory which the discusser advanced several years ago to explain brush contact drop characteristics. The authors were asked a number of questions about the physical properties and mechanical conditions in connection with their work and points with which the discusser was not in agreement were cited.

### SINGLE-PHASE SHORT-CIRCUIT TORQUES OF SYNCHRONOUS MACHINES

L. A. Kilgore (East Pittsburgh, Pa.) in his discussion of this subject felt that the authors had presented a relatively simple solution to the difficult problem of calculating the pulsating torque of single-phase short circuits. He explained that the extended 2-reaction theory and the constant interlinkage theorem were applied to include the effect of direct and quadrature axis damping circuits.

Another discussion of this subject by B. L. Robertson (Berkeley, Calif.) made reference to the previous work on synchronous machines by Doherty, Penny, and others. The assumptions of, and conditions set forth in previous work were compared with those in the present paper, the discusser also pointing out the continued use of the theorem of constant linkages.

### WIRE COMMUNICATION AIDS TO AIR TRANSPORTATION

H. T. Killingsworth (Cleveland, Ohio) in connection with this subject described the communication equipment of the Cleveland airport, which includes practically all of the features described in the paper. Five teletypewriter circuits radiate from Cleveland, paralleling the more important routes. The administration building which contains this equipment is connected to the long wave radio transmitting station, urgent messages being retransmitted to planes in flight by the use of the re-perforating equipment. Short wave radio equipment is used by the airport authorities in dispatching planes, both upon leaving and landing at the field.

### CHARACTERISTICS OF ELECTROMAGNETIC RADIATION FROM AIRCRAFT IN FLIGHT

The authors, J. C. Coe and T. C. Rives, were asked several questions concerning the possibility of obtaining effects similar to fading when flying rough, the factors upon which the distance free from fading depended, and comparisons between different types of antennas. It was explained that good flying conditions were encountered during these tests, and that variation in field strength would be due much more to the changes in orientation of the transmitting antenna with respect to the receiving antenna than to an actual change in altitude or distance. The attenuation undergone by earthbound rays was found to be independent of whether daylight or darkness obtained, and fading was encountered when the field strength became less than a certain value, this value depending upon frequency, time of day, etc. With regard to effects with the different types of antennas, it was explained that where distances are much greater than altitude, the trailing wire antenna would give a greater field strength; and as to the distance free from fading, this also would be favored by the trailing wire antenna rather than by the horizontal type.

### VERTICALLY CUT SOUND RECORDS

In connection with this subject Benjamin Olney (Rochester, N. Y.) discussed the practical limitations which prevent the radio broadcasting and receiving of high quality music as demonstrated by the authors. To obtain a high frequency range in radio reception comparable to that which was demonstrated, the following steps would be necessary aside from merely extending the frequency range of both the radio receiver and the broadcast system: (1) frequency spacing of adjacent broadcast channels must be doubled; (2) the effective power must be increased to provide a greater signal noise ratio; (3) carbon button microphones must be used with caution or eliminated; and (4) transmitter overmodulation must be avoided to a much greater extent than at present. Also space limitations in the home would constitute the principal limiting factor of low-frequency reproduction.

### Adequate Wiring of Buildings

Philip Sporn (New York, N. Y.) in his discussion of this subject felt that the engineering profession as a whole, and the membership of the Institute in particular, had not given sufficient attention to this subject. He hoped that the paper on this subject might serve as a prelude to others which might describe advances and new developments in this field. One of the important reasons for the lack of progress in this field was thought to be due to the general belief that the National Electric Code has a legal status, and that there is nothing engineers can do except comply with this code. He pointed out that the code has no legal status of any kind except that which is given to it by municipal or other ordinances, and such legislation might call for installations in direct contradiction to the code.

J. M. Bryant (Minneapolis, Minn.) also discussed this subject and felt that the Institute should cooperate with standardizing bodies in the adoption of new codes of wiring. An increase in the standards for wiring so that conductors in new structures would have sufficient capacity to permit increasing the illumination was recommended. He believes that there is no type of building which better illustrates the changing tendencies than do the public school and buildings in institutions of higher education. An actual experience was cited and served to illustrate this point.

F. C. Caldwell (Columbus, Ohio) in discussing this subject referred to a simple application of differential calculus which showed that the greatest economy of copper for a 2-wire system will be attained when the permitted voltage drop is divided between a feeder and its branches, in proportion to the length of the feeder and the average length of the branches. Similar relations for 3-wire feeders could be worked out with any given relation of neutral to outside wire. This simple principle he stated has never been observed in treatises on wiring.

Another discussion on this subject by L. W. W. Morrow (New York, N. Y.) brought out that there are 3 aspects of wiring and lighting that should receive serious consideration by every man in the industry. These are the humanitarian, business, and technical aspects. With regard to business possibilities, he pointed out that a 30-story office building offers a load in the neighborhood of 36,000 kw. High-grade engineering and detailed attention is devoted to a 500-kw. industrial power load; although the lighting load is infinitely the larger, it receives but little attention. Also, each home market if adequately sold and engineered offers from 10 to 15 kw. of load. He felt that no more fruitful field for engineering than this existed in the industry, and that it should have serious attention.

A discussion by Morgan Brooks (Urbana, Ill.) referred to means for revising inadequate house wiring without recourse to complete replacement. He also brought out that the predicted installation of air-conditioning apparatus in homes makes adequate wiring a debatable question. As a remedy, he stated that often where coffee urns, toasters, and chafing dishes affect dining room illumination adversely, a single additional circuit can be installed economically, connected to the opposite side of the distribution system. Also judicious reconnection of circuits at the cut-out cabinet may save the expense of rewiring.

Taylor Reed (Reedsville, Pa.) recommended that there should be a revised code on adequate wiring of buildings to set limits of permissible momentary dip of voltage.

Another discussion of this subject by P. L. Alger (Schenectady, N. Y.) suggested that the wiring code committee prepare a supplement to the standard code to explain the minimum character of standard code provisions and give detailed figures on the possible savings to be made by the use of larger wire sizes and more numerous outlets.

### Current Propagation in Electric Railway Propulsion Systems

K. L. Maurer (New York, N. Y.) discussed this subject and pointed out that the peculiar feature of the type of circuit treated in this paper, as distinguished from the ordinary power circuit, is that one side is made up of a concentrated metallic conductor in parallel with a distributed conductor, the earth. The effect of the earth as a conductor, upon the electrical constants, cannot be neglected as ordinarily it might be in the case of the usual power circuit.

### Application of High-Speed Relays

E. H. Bancker (Schenectady, N. Y.) in his discussion of this subject felt that papers of this type which presented results actually attained in operating practise, were valuable as they point out to designing and application engineers factors which have been overlooked or neglected. In this way such papers offer the opportunity for a further improvement in protective relaying. These remarks were illustrated by several cases taken from the paper and analyzed by the discusser.

### A New High-Speed Reactance Relay

In connection with this subject Philip Sporn (New York, N. Y.) stressed the fact pointed out in the paper, that in spite of the high cost, because of the need of high-voltage instrument potential transformers, any system of distance relaying gives high speed protection for only about 80 per cent of a line section. He then referred to the pilot scheme for universal protection and the objections to using a separate set of pilot wires. As a solution to this difficulty, recourse was taken to the use of carrier current and tests which have been conducted. He explained that the scheme was a true power directional plan of protection, utilizing carrier current to perform strictly one function. Fast tripping relays in a section are locked out when the fault is external to that section; when the fault is internal, the fast relays will operate. Results of these tests showed that tripping under all conditions could be obtained in a maximum time of 3 cycles on a 60-cycle system.

### Relay Operation From Bushing Potential Devices

A discussion of this subject by H. A. P. Langstaff (Pittsburgh, Pa.) which told of

## Additional Locomotives for the Pennsylvania Railroad

FIVE of the electric locomotives for high speed passenger service on the Pennsylvania Railroad are shown in the test yard of the Erie, Pa., works of the General Electric Company. Each locomotive weighs 190 tons, and is rated as 3,750 hp.

the successful operation and functioning of a number of these bushing potential devices in service, was read by Mr. Langguth. When these devices were used for relays, Neon lamps or a high resistance voltmeter was recommended for checking the voltage which would assist materially in the finding of trouble that might occur within any of the circuits between the bushing and relays. Another point brought out was that no proof was actually obtained of the belief that atmospheric conditions have a limited effect upon the accuracy of the potential as obtained from these devices.

### THE BORIC ACID FUSE

T. G. LeClair (Chicago, Ill.) discussed the features of this new fuse and he felt that the lack of an inflammable liquid filler was an excellent safety measure. He inquired about an opening in the inclosed type for the escape of gases, and the effect of failure when called upon to interrupt a current beyond its capacity.

### SUPERVISORY CONTROL SYSTEMS

M. E. Reagan (E. Pittsburgh, Pa.) described the history of this development. It was interesting to note that the first comprehensive system of remote control and supervision of a large number of operations over a group of common line wires was put into operation at Cleveland in 1922. He also commented on how the fundamentals in these early installations stood the test of time, and are today relatively unchanged. The only addition to the excellent specification for performance appeared to be the anti-pumping control as presented by Mr. Oliver.

J. H. Oliver (Philadelphia, Pa.) discussed the operating experience obtained from the Reading Company's installation, emphasizing the last paragraph of the paper which reported that no trouble had been experienced from induction, no faulty indications or operations had been observed or performed, and no train delays had been caused by failure of the supervisory control equipment. The discusser also pointed out that more maintenance was required where several stations are operated in parallel on the same common conductors than when individual wires and individual systems are used for the control of each station.

### APPLICATIONS AND PERFORMANCE OF AUTOMATIC EQUIPMENT

A. E. Anderson (Philadelphia, Pa.) in his discussion of this subject referred to the extensive use that has been made of the system of the American Gas and Electric Company. With regard to the economics of this equipment he pointed out that investments in automatic switchgear permit reduction in operating costs. In some cases it was possible to remove enough feeder copper to pay for a large share of automatic control. However, he brought out that with the increased reliability and speed over manual operation, together with other attendant developments, economics sometimes are of secondary consideration.

Another discussion by Robert Treat (Schenectady, N. Y.) demonstrated, by quotations from the paper, that a certain course of procedure results in a collateral and perhaps unexpected advantage which is more important or more valuable than the primary objective originally sought. As was found in the paper the automatic substation is often less expensive to operate than an equivalent attended one. But by its reliability, speed of action, and freedom from errors of judgment, the automatic station gives a brand of service which cannot be approached by even the best attended substations.

### REPORT ON TELEMETERING, SUPERVISORY CONTROL AND ASSOCIATED COMMUNICATION CIRCUITS

C. G. Wassal (Cleveland, Ohio) commended the committee for offering such a thorough presentation. He believes the report filled a need felt for a long time and it should result in a much closer coordination between the 3 groups, the manufacturer, the user, and the companies furnishing circuits for such purposes. It also was brought out that the communication circuits used for telemetering require 24-hour maintenance and in addition for open wire routes, alternate routes seemed advisable in case of a base channel failure.

Another discussion of the report was presented by P. MacGahan (Newark, N. J.) and called attention to the importance of the communication line problems. He also told of one of the earliest telemetering systems which was of the frequency class and installed on the Chicago, Milwaukee, and St. Paul Railroad. He explained that the impulses and the current balance systems have entirely superseded the frequency system in modern installations. He also referred to a report on remote metering by the committee on instruments and measurements in the A.I.E.E. TRANS., v. 47, 1928, p. 1164, and he felt that the present report might be considered as an extension of the same subject.

### STRESS-STRAIN STUDIES OF CONDUCTORS

J. A. Inglis (Toronto, Can.) believes the paper on this subject very interesting from the point of change in values of the modulus of elasticity of a cable. He felt it would be interesting to know if during these tests basketing or bird-caging was experienced at end conditions or connections, and if any records were taken of rotation. He also cited the importance of fatigue limits and suggested that it would be most advantageous if they were tabulated for the various metallic cables.

### VIBRATION AND FATIGUE

In connection with this subject F. E. Andrews (Chicago, Ill.) explained that there are several 3-strand conductors now on the market, notably one of high strength material made by the Aluminum Company of America. Inquiry was made about experience with the use of sleeves on this conductor and if any special sleeve was necessary.

M. E. Noyes (Pittsburgh, Pa.) replied to the suggestion in the paper that different types of stranding of cables should be compared to determine their relative ability to dissipate energy by interstrand friction. He explained that this had been done successfully in the laboratory of his company on 120-ft. spans using a decrement method, by Mr. Kimball. The decrement of amplitude was measured from a trace taken after the source of forced vibration had been suddenly disconnected from the cable. This value is then substituted in the Kimball formula. Concerning consideration of new cross-section shapes and new types of stranding, Mr. Noyes called attention to the possibility of severe stress concentrations which might occur at span ends due to abrasions of the surfaces of wires. In his opinion any cross-section shapes of conductor which caused certain strands to stand out sharply would be liable to higher stress concentrations than the usual round cable.

### VIBRATION OF OVERHEAD TRANSMISSION LINES

E. W. Dillard (Boston, Mass.) described field tests and experiences on the Fifteen-Mile Falls transmission line in connection with disruptive corona as a third cause of vibrating conductor. A test span, the exact duplicate of one of the spans on the line, was erected to confirm this hypothesis by experiment under controlled conditions. Rows of sprinklers installed above the span provided precipitation at will. Under simultaneous conditions of low wind velocity (under 4 miles per hour) and precipitation, vibrations were produced in all sizes of conductors from No. 14 AWG stranded copper antenna wire to 795,000-cm. A.C.S.R. with the exception of No. 4/0, 7-strand, hard drawn copper which seemed to have inherent mechanical characteristics which suppressed any tendency toward vibration. Conditions observed on the Fifteen-Mile Falls line and on the California-Oregon Power Company's system showed that vibration occurred on the 2 systems under identical conditions. This data led to several new principles in regard to conductor vibrations.

Another discussion by C. B. Basinger (Cambridge, Mass.) read by F. E. Deck, presented results of experiments made by H. L. Richardson (Cambridge, Mass.) and the author of the paper, at the Massachusetts Institute of Technology, to study the forces which act on a moving conductor surrounded by corona discharge. These studies showed that a force exists which is a function of the voltage on the conductor and of the velocity of the conductor relative to the air. In general, it is necessary for the conductor to be energized above the corona voltage and over the range studied a further increase in voltage increases the force.

### VIBRATIONS DUE TO SLEET

F. E. Andrews (Chicago, Ill.) also discussed this paper and he felt that the subject discussed was that which is generally known as "whipping" rather than "vibration." He also believes the conclusion in the paper, that change in span length or change in tension of the cable does not effect the phenomena, is contrary to generally established formulas for traveling waves in a conductor. To him it seemed impractical to predict whipping by the application of the formulas developed.

Another discussion by L. L. Perry (Chicago, Ill.) gave evidence of extraordinary weather conditions in Illinois and Indiana on March 21, 1932. Conditions produced sufficient dancing of conductors to trip out 132-kv. circuits of both A.C.S.R. and copper. At Chicago the temperature range was only from 29 deg. fahr. minimum to 30 deg. fahr. maximum with a maximum wind of 35 miles per hour. Other conditions were cited and apparently all tripouts occurred at one point, as evidenced by burns on the conductors and ground wires. At this point only, the line had a diagonal run with about a 90-deg. angle with the wind.

A. E. Davison (Toronto, Can.) discussed this subject and cited the importance of keeping it prominently before engineers and executives. He referred to galloping as evidenced within a 100-mile radius of Niagara Falls with sleet loading and winds at 5 to 15 miles per hour. These conditions were shown by Mr. Davison from a film obtained through the kindness of the Niagara, Lockport and Ontario Power Co. In regard to this paper he explained that it correctly pointed out that in earlier references to "lift," "drag" studies were omitted. He felt also that there should be general agreement with the authors' conclusions.

## 1932 Lamme Medal Nominations Due Nov. 1

In fulfilment of By-Law requirements, a second posting is hereby given to the necessity of all nominations for the Lamme Medal for 1932 being submitted not later than November 1, 1932. (See Electrical Engineering, June 1932, p. 417.)

Presentation of the 1931 Lamme Medal was made to Giuseppe Faccioli (F'12) consulting engineer (retired) General Electric Company, Pittsfield, Mass., at the opening session of the Institute's recent summer convention at Cleveland, Ohio.

**Three thousand radio receiving sets** now can operate independently on the same antenna without interfering with each other, according to an announcement by the Western Electric Company. The system is designed primarily for hotels, apartments, and other multiple dwellings, and is arranged to overcome the increasing problems which dwellers in such buildings face in obtaining good antenna facilities for their radios at reasonable cost. The principles employed in long distance telephone circuits are used in this equipment. The receiving system is protected against interferences which the ordinary lead-in wire commonly picks up from sources within a building, and the loss in receiving power usually caused by the great length of lead-in wire and its high capacity to ground is overcome. Each receiving set connected to the system is electrically isolated so that it cannot put any noises back into the system to disturb the operation of others on the line. The receiving set may be of any make the individual chooses. A vital part of the system is the "coaxial conductor" which serves as a lead-in wire. A lightning arrester, repeating coil, filters, an amplifier, and lines radiating throughout the building make it possible for each user to connect his set by plugging into a convenient socket. Smaller forms of this equipment are available also, and are suitable for even the individual home owner with only one radio receiving set.

## Frank J. Sprague Receives Many Tributes

A feature of the meeting honoring Frank J. Sprague (A'87, F'12, HM'32 and past-president) and which was held in the Engineering Societies Building, New York, N. Y., on July 25, 1932, was the presentation to Doctor Sprague of a handsomely bound collection of nearly 500 letters of congratulation and appreciation. The existence of these letters was not known to Doctor Sprague until the conclusion of the meeting when they were presented to him as a complete surprise.

The program, as announced in Electrical Engineering for July 1932, p. 526, included speeches of tribute delivered by Dr. J. H. Finley, associate editor of the New York *Times* and former commissioner of education for New York City, Frank Hedley, president of the Interborough Rapid Transit Company, New York, N. Y., Rear Admiral S. S. Robison, U.S. Navy, retired.

Classifying Doctor Sprague as having "the same relation to electric transportation that Thomas A. Edison bore to electric illumination," Mr. Hedley in his address stated further that "Doctor Sprague has not rested with the mere inventing or suggesting of new methods. He has recognized that the world often is too busy to pay attention to new and advanced ideas which are considered revolutionary, or to give them a trial unless forced to do so, and he has made it his business to do the necessary forcing. . . . He knows what it means to have the signals set against him and to be forced onto a side track and delayed. Nevertheless . . . his inventions have proved worth while and he had sufficient faith in them to fight for them, even when confronted with discouraging conditions and fierce competition." Mr. Hedley mentioned the modern multiple unit electric train control as exemplifying the importance of Doctor Sprague's contributions to transportation developments, and said " . . . The traveling public owes and always will owe a tremendous debt to him."

Doctor Sprague acknowledged the tribute in a short response, expressing his thankfulness at having been able to be of service to his fellow men in facilitating their convenient transportation. After mentioning briefly some features of his own work, Doctor Sprague ventured the opinion that although other modes of transportation are becoming more important, the railroads still remained the "vital foundation of the country." He stated further that "it would be folly to predict in the present low state of competitive traffic and world wide financial depression, that general electrification is advisable or even permissible in the near future. However, if some of the hundreds of millions of capital which the national government is ready to dole out for unproductive public works were diverted to legitimate and sane electric railway equipment a long step would be taken toward economic recovery."

Doctor Gano Dunn, past-president of the Institute (1911–12) presided over the meeting as chairman of the anniversary committee which included in its membership list a galaxy of names prominent in professional, educational, electrical, and transportation fields. Dr. C. T. Hutchinson (F'12) consulting engineer of New York City served the committee as its secretary, while Frank Hedley, W. B. Potter (M'96), G. A. Richardson (A'08), and F. H. Shepard (F'24) served the committee as its working unit.

**Wood Poles for Overhead Electrical Lines.**—The Bureau of Standards of the U.S. Department of Commerce has issued Handbook No. 16 on the subject of "Wood Poles for Overhead Electrical Lines." It is for sale by the superintendent of documents, Washington, D. C., price 10 cents, and contains considerable data on this subject.

## Doctor Flinn Receives Honorary Degree

On June 17, 1932, Dr. A. D. Flinn, who since 1922 has been director of Engineering Foundation, New York, N. Y., received the honorary degree of doctor of engineering from Worcester Polytechnic Institute, Worcester, Mass. Doctor Flinn, a native of the state of Pennsylvania, received his bachelor of science degree from Worcester Polytechnic Institute in 1893, and in 1927 received the degree of doctor of applied science from the University of Louvain.

Doctor Flinn, a civil engineer, has been concerned for many years with the activities of the entire engineering profession. Between 1895 and 1918, he was successively engineer with the Metropolitan Water Works, Boston, Mass., managing editor of *Engineering Record*, New York, N. Y., engineer on the Croton Aqueduct Commission, and deputy engineer and deputy chief engineer of the Board of Water Supply, New York, N. Y. (Catskill aqueduct). Since 1918 his office has been in the Engineering Societies Building where he has served since that date as secretary of the organization carrying successively the names, United Engineering Societies, Engineering Foundation, Inc., and United Engineering Trustees, Inc. From 1918 to 1921 he also was secretary of the Engineering Council. In addition to being director of Engineering Foundation since 1922, he has been secretary of that organization since 1918.

Doctor Flinn was a member of the National Research Council, 1918–1923, and chairman of its division of engineering 1920–1923. His technical affiliations include fellow of the American Association for the Advancement of Science, member and past director of the American Society of Civil Engineers, and member of the American Institute of Mining and Metallurgical Engineers, the American Iron and Steel Institute, and the American Society for Testing

Materials. He is honorary foreign member of the section of engineering societies of the Masaryk Academy, Czechoslovakia, Knight, Order of the White Lion, Czechoslovakia, and member of the Japan Society, Sigma Xi, Sigma Alpha Epsilon, the Engineers' Club, and the Century Association. Doctor Flinn was a joint author of the "Waterworks Handbook" published in 1916, and has been a contributor of numerous papers and articles on engineering topics.

## Airship Institute Dedicated at Akron

The new Daniel Guggenheim Airship Institute at Akron, Ohio, was dedicated with impressive ceremonies on Sunday, June 26, 1932. The program included a communication from Harry F. Guggenheim, president of the Daniel Guggenheim Foundation for the Promotion of Aeronautics, and addresses by Dr. G. F. Zook, president of the University of Akron, and Dr. R. A. Millikan (M'22), chairman of the executive council of the California Institute of Technology, Pasadena. This Airship Institute at Akron has been made possible by a gift of $250,000 from the Guggenheim foundation to both the University of Akron and the California Institute of Technology for the study of lighter-than-air problems. The gift was supplemented by $100,000 from the city of Akron. After expenditures for building and equipment, funds remained for the conduct of research work during the next 5 years. A most important part of the equipment is a vertical wind tunnel, the largest in existence.

On the second day, June 27, a conference was held on progress and problems of research in lighter-than-air craft, with Dr. R. A. Millikan as chairman. Among the large number of speakers, all outstanding experts in aeronautical engineering and research, who took part in this conference are: Karl Arnstein, vice-president in charge of engineering, The Goodyear-Zeppelin Corporation; Garland Fulton, chief of lighter-than-air section, Bureau of Aeronautics, U.S. Navy Department; J. C. Hunsaker, vice-president and general manager, The International Zepplin Corporation; Theodor von Karman, director, The Daniel Guggenheim Airship Institute; W. E. Kepner, Air Corps, Wright Field; and C. B. Fritsche, general manager, Detroit Aircraft Development Corporation. The subjects discussed during this conference fall under the following headings:

1. Aerodynamics of airships.
2. Thermodynamics.
3. Meteorology.
4. Structural analysis.
5. Instruments.
6. Engines and power plants.
7. Materials.
8. Aerostatics.

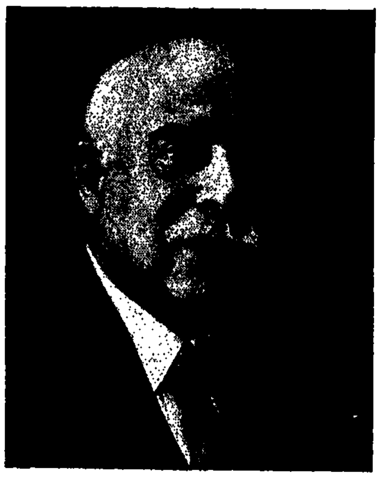
Dr. C. E. Skinner (A'99, F'12, and junior past-president) served as the representative of the A.I.E.E. at the exercises on June 26 and 27. The following statement, taken from a letter of Doctor Skinner's reporting the exercises, summarizes the purpose of The Daniel Guggenheim Airship Institute and its relation to electrical engineering:

"This Institute is to be devoted entirely to the study of problems incident to the building and operation of lighter-than-air craft. Many of the problems which have been selected for study and experiment have a very direct relation to the problems in electrical engineering, and I have no doubt that on this account our Institute would do well to keep in touch from time to time with the work of The Daniel Guggenheim Airship Institute.

"The problems of most direct interest are probably those having to do with the movement of air through passages, the surface friction of air over bodies, the transfer of heat, etc. These all have direct relation to the problem of ventilation in electrical machinery. There are many other problems in connection with the physical characteristics of construction and materials, the study of stresses and strains in structures, etc., which have a less direct bearing but which are similar to problems encountered in the construction of electrical machinery and apparatus."

## Doctor Burgess, Leading Physicist, Dies

George Kimball Burgess, director of the U.S. Bureau of Standards, Washington, D. C., died suddenly on July 2, 1932, of cerebral hemorrhage. Doctor Burgess was born at Newton, Mass., in 1874, receiving his bachelor of science degree from Massachusetts Institute of Technology in 1896, and the degree of doctor of science from the University of Paris in 1901; honorary degrees of doctor of engineering were conferred upon him by Case School of Applied Science, 1923, and Lehigh University, 1925.



GEORGE K. BURGESS

Between 1896 and 1903, Doctor Burgess taught physics at M. I. T., the University of Michigan, and the University of California. Since 1903 he has been connected with the Bureau of Standards, being successively assistant physicist, associate physicist, physicist and chief of the division of metallurgy, and since 1923, director, in which position he succeeded the first director, the late S. W. Stratton. High temperature measurements and metallurgy were the fields in which most of his scientific work as a physicist was concentrated; among his noteworthy achievements are the application of optical pyrometry to metal in furnace and rolling processes. His work on standards for light measurement, details of rail structure, causes of rail failure, and many other phases of metallurgy was outstanding and has continued to be of considerable assistance to workers in these fields. A large expansion of the bureau's activities occurred while he was director, and he was responsible for the development of the research associate system under which industries carry on research work at the bureau through their own employees advised and assisted by the staff experts of the bureau.

Doctor Burgess contributed freely of his time to the work of scientific and technical societies. Among the societies of which he was a member are the National Academy of Sciences, American Society for Testing Materials (past-president), National Research Council (chairman), American Society for Steel Treating (past-president), American Engineering Standards Association (director), the American Institute of Mining and Metallurgical Engineers, the American Physical Society, and the Optical Society of America. He was an honorary member of the American Foundrymen's Association, and the Japanese Society of Mechanical Engineers. He had also been chairman of the federal specification board and the national screw thread commission, and a member of the national advisory committee for aeronautics. In 1927 he was U.S. delegate to the seventh international conference on weights and measures in Paris, in 1929 was U.S. delegate to the world engineering congress in Tokyo, and had been president of the Annual Conference on weights and measures. He was a member of Sigma Xi fraternity and the Cosmos Club. In addition to many scientific articles and papers, he was the author of "Recherches sur la constante de Gravitation," 1901; "Experimental Physics—Freshman course," 1902; and "The Measurement of High Temperatures" (with H. Le Chatelier) 1912.

## Insulation Committee to Meet in Baltimore

The electrical insulation committee of the National Research Council has announced its plans to hold its regular annual meeting at The Johns Hopkins University in Baltimore, Md., at the same time that the A.I.E.E. Middle Eastern District is meeting there. This will facilitate a joint meeting of these organizations tentatively scheduled for Monday afternoon, October 10, at which time 4 papers in the field of high voltage underground cable insulation and performance will be presented.

Two other technical sessions of the electrical insulation Committee will be held. In those sessions the results of recent research in the fields of dielectrics and insulation will be presented in the form of informal reports of progress made by manufacturers, scientific societies, and governmental and university laboratories. These sessions are scheduled to be held at the School of Engineering, Johns Hopkins University, under the general supervision of Dr. J. B. Whitehead, who is chairman of the committee.

# Letters to the Editor

CONTRIBUTIONS to these columns are invited from Institute members and subscribers. They should be concise and may deal with technical papers, articles published in previous issues, or other subjects of some general interest and professional importance. ELECTRICAL ENGINEERING will endeavor to publish as many letters as possible, but of necessity reserves the right to publish them in whole or in part, or to reject them entirely. Statements in these letters are expressly understood to be made by the writers; publication here in no wise constitutes endorsement or recognition by the American Institute of Electrical Engineers.

## Labor and Engineering Progress

*To the Editor:*

Mr. William Green's contribution to the symposim on "Has Man Benefited by Engineering Progress" (see "Labor and Engineering Progress," ELECTRICAL ENGINEERING, May 1932, p. 318–9) is, to my mind, the most encouraging contribution yet received.

Its depth of view and understanding is wonderful evidence that one need not necessarily have had a typical engineering education to have the engineer's method of approaching a difficult subject.

Most of all, it is encouraging to me, because it contains the first invitation that engineers have received from one not in their profession, to expand their field of usefulness to mankind.

We, as engineers, have had exceptional advantages and some of us have had the courage to say that our methods should be extended into other fields, including that of human relations, but no such suggestion has come to us from bankers, lawyers, or politicians.

That such an invitation should first come from a self-made man, like Mr. Green, who is president of the world's greatest labor organization, is indeed encouraging indication that engineering methods are beginning to be appreciated outside the profession.

I sincerely hope that the Engineering Foundation and American Engineering Council will both find ways and means to cooperate with Mr. Green.

Very truly yours,
W. S. MOODY (F'12)
(Consulting Electrical Engineer,
155 Dawes Ave.,
Pittsfield, Mass.)

*To the Editor:*

The article by Mr. William Green on "Labor and Engineering Progress" in ELECTRICAL ENGINEERING for May 1932, p. 318–9, is a fine contribution to the economic recovery of the country.

There is no doubt but that the present machine age with its mass production, efficiency systems and the infinite number of labor saving devices, requires a compensator in the form of a shorter work week.

When the salesmen find that their former customers cannot buy their goods due to their being out of employment, business suffers, also machinery and plants become financially insecure.

Real prosperity demands that the maximum number be employed. At no additional expense to the employer the present man-hours of work should be apportioned so that the weekly amount of work will be done by more workers. The work week should be shortened, keeping the same hourly rate of pay, until all unemployment is absorbed. We are being forced to this conclusion. The longer the delay the harder it will be to recover.

When all who want to work are employed, business will soon pick up, with leaps and bounds, due to available money to spend, which will create a healthy demand. Salesmen will be happy and salaries will rise as the general prosperity increases.

Production will be balanced by work hours.

Very truly yours,
H. S. HALL (M'25) (616 East
8th St., Brooklyn, N. Y.)

*To the Editor:*

After reading that most commendable article, "Labor and Engineering Progress" by William Green, which appeared in ELECTRICAL ENGINEERING for May 1932, p. 318–9, the writer was moved to wonder if this article and articles of a similar nature in this series, as well as the President's message, have made any deep impression on engineers at large. It seems that most engineers are all too prone to lose themselves in the maze of technical work and lose sight of the less tangible problems mentioned in above paper, the equitable distribution of goods, profits, and labor. These are certainly complex problems which are worthy of an engineer. Since the engineer is largely responsible for the creation of the giant, machine age, which is threatening to annihilate us in its unguided and staggering course, surely he is not going to sit down and leave to bungling politicians the task of providing a system of control for his robot. In other words, the engineers' work is only partly done and he must devote some of his time to the solution of these important problems.

It does not seem enough to utter a mild appeal to members at large to take a more active interest in such matters or to leave the burden of their solution to a few engineers who are actively engaged in politics, for it seems that a few men with ideas cannot put them into effect without strong support. If anything of value is to be arrived at, it requires concerted effort from the engineering body as a whole. Of course, every engineer should acquaint himself more with the matters of government, finance, and politics than he has done in the past, and should have no hesitancy in coming forward with criticisms, ideas, etc., at any time. Now it seems that this concerted effort of the engineers should be directed by the various engineering societies, that is, why should not each engineering society have a special committee of notable engineers to investigate and present reports and recommendations on these problems from time to time in the same manner they would investigate a special phase of technical work. Thus the engineers as a body would be in a position to offer solutions to pressing problems and to exert the necessary pressure for their adoption in industry and government. If the President had such a body behind him, he could effect many of the necessary reforms which he, no doubt, has in mind and is at present almost powerless to carry out due to strong group opposition. Therefore, it is time the engineer cast aside his habitual reserve and deference to the politician and join the fray in a concerted effort to find a scientific solution to the problems which urgently need solving.

It is not assumed that all our difficulties would be solved by the magic touch of the engineer, or we would arrive at the millennium at once, but it certainly seems that more active and concerted effort by the engineers in the solution of these difficulties would be preferable to experiments of bolshevism or socialism which may come unless the machine age is put under sensible control. No doubt the suggestions outlined above will provoke some criticism and suggestions. If so, this letter has accomplished its purpose.

Very truly Yours,
J. R. HANGO (A'31)
(Arvida, P. Que., Canada)

## Reactive Power Units and Terms

*To the Editor:*

I desire to call attention to the apparent disregard of the "unit of reactive power" and the term "reactive power."

The adoption of this unit—the "var"—and the provisional adoption of the term "reactive power" by the International Electrotechnical Commission in session at Oslo, July 1930, were reported in ELECTRICAL ENGINEERING for February 1931, p. 142.

It would be unreasonable to expect all authors to adopt these conventions immediately, but I do believe that our committee reports should utilize any and all definitely adopted nomenclature, thus hastening its general usage.

It is quite possible that I have overlooked some article using the "var" but to the best of my knowledge the unit has not been used until in A. E. Kennelly's article, "Recent Developments in Magnetic Units," in ELECTRICAL ENGINEERING for May 1932, p. 343–5. The adoption of a unit of reactive power comparable with the unit (watt) of active power is a valuable advance, as the "reactive voltampere" has been a cumbersome unit.

In respect to the term "reactive power," though only provisionally adopted, the desirability of its use in conjunction with "active power" is, I believe, obvious. Reactive voltamperes as a term has no more excuse for its use than has its complementary term active voltamperes. By refraining from the use of either of these (reactive voltamperes and active voltamperes) the unit of apparent power—the voltampere—is available without the slightest need of the qualifying prefix "apparent." Thus 2 distinct phases of the power expression are provided:

1. **Apparent Power = Active Power $\pm j$ Reactive Power**
2. **Voltamperes = Watts $\pm j$ Vars**

In a recent committee report, "Proposed Definitions of Terms Used in Power System Studies" (No. 31M2) and some other articles, the convention $P \pm jQ$ has been used to represent the right hand side of the above equations. This is leading us directly into an ambiguous situation. $P$ is commonly accepted as the symbol for power. And power has been commonly used interchangeably with active power, though it is becoming more apparent that this is a serious error—as attested by the increasing interest in the reactive power component in energy sales considerations, and the difficulty of explaining this new factor to the layman.

It is certain that a considerable amount of educational effort will have to be expended to clarify this situation. Why not make as much gain as is possible since some revising is necessary. Two lines of procedure are suggested to me. They are:

1. Place power on the left side of eq. 1, that is, drop the "apparent" from power as we did above from voltamperes, making the unit of power the voltampere, of active power the watt, and of reactive power the var. This is the preferable though more radical change.

2. Continue the use of power in lieu of "active power" and adopt some other term for reactive power (quadro is suggested to me by the symbol $Q$). "Apparent power" is still a source of trouble and should be replaced by some other term.

According to A.I.E.E. Standard, "Letter Symbols for Electrical Quantities" (17g1), $A$ and $S$ are available for assignment as symbols. $A$ is readily adaptable as the symbol for active power in suggestion 1 above.

$$\text{Power} = \text{Active Power} \pm j\,\text{Reactive Power}$$
$$P = A \pm jQ$$

For active power the symbol $A$ could nicely represent apparent power, although the letters $VA$ are quite suitable:

$$\text{Apparent Power} = \text{Power} \pm j\,\text{Quadro}$$
$$VA = A = P \pm jQ$$

I further wish to indicate that I favor the convention watts $\pm j$ vars to represent active power and leading reactive power as tentatively adopted by the committee.

Very truly yours,
FRED B. IRWIN (A'31)
(1430 Hawthorne Avenue,
Portland, Oregon)

## The Way Out of the Depression

*To the Editor:*

In response to the invitation to discuss the article "Progress Is the Way Out of the Depression" by Mr. A. W. Berresford in ELECTRICAL ENGINEERING for December 1931, I am sending the following: The first paragraph contains a statement about the depression that seems extraordinary for an engineer to make. "There is little of value at the moment in attempting to isolate and correct the major causes." Can we imagine this attitude applied to any engineering work? Can we imagine an engineer saying that there is little value in trying to isolate the causes after a bridge or a dam failure? Can we imagine an engineer saying, after a bridge failure, that the causes will gradually emerge as time provides a perspective? To be sure, study of the causes will not rebuild the bridge, but it may prevent a second failure.

If the solution is left to time, we are likely to see the economic and social errors that produced the dark ages repeated; in fact, much of the "quantity of understanding" which Mr. Berresford says has increased so much within the last 18 months seems to be a reversion to the errors refuted by the economists of the last 200 years.

"The mere fact that stabilization of employment is economically dependent upon controlled production, and consumption dependent upon stabilized employment, will unite all elements in a common demand for that solution." This statement forms the basis of many of the popular fallacies, chiefly because it is so plausible. But nature has decreed otherwise. As long as the farmer does not know whether he will get 10 bushels or 40 bushels when he plants an acre of ground, stabilized production is impossible. To attempt stabilization probably will cause greater instability.

Consider a state with industrial activities stabilized to the greatest possible extent. Each company has its quota of production with the men for whom it is responsible. Now nature produces an unexpected crop, 25 per cent greater than the farmers had planned. This leaves a surplus for next year, so that there should be a reduction of 25 per cent in the number of men on the farms for the next year. With every industry stabilized where are they to go? Instead there is an unemployed surplus of men on the farms with resulting distress and reduced purchasing power. This in turn affects the industries, reducing the possibility of employment, and consuming reserves if any have been accumulated. The attempt to maintain stability is an attempt to thwart economic laws; but the laws will win and worse troubles develop.

What we need is flexibility, not stability. We need a mobile labor force as well as flexibility of management. We need industries that can increase or decrease their working forces according to conditions, and we need an economic inducement to make them increase and decrease at the right time for the public good.

One simple inducement which can be applied without much change in the present economic structure consists of an expansion of the currency with falling commodity prices. When a surplus crop is produced, the currency should be expanded to hold a large part of this crop over for a future year. The expansion of currency will result in stimulating industrial demand so as to provide jobs for the farm help released by the excess crop. This is only one step, and it will not prevent unemployment or business depressions altogether, but it is a step in the right direction. A more important step is the reorganization of education; but that is too complicated a problem to discuss here. The important thing to keep in mind is that whatever action is taken, it should be to provide greater flexibility, to make it easier for men to change from one kind of work to another as conditions change. It should tend to break the ties that now too strongly bind men to the jobs where they long have worked.

Very truly yours,
A. W. FORBES (A'12) (Forbes
and Myers, 172 Union St.,
Worcester, Mass.)

## Paralleling Rotor and Stator

*To the Editor:*

In the March issue of the ELECTRICAL ENGINEERING appeared an article based upon an interesting paper by Conrad and Warner: "Induction motors with parallel rotor and stator." The synopsis of the complete paper points out that "this method of operation was new to the authors and to several eminent induction motor designers and as no reference has been found to others employing this principle . . ." etc. In connection with this statement, it may be of some interest to both authors and readers, to learn that the same subject has been covered in the Archiv fuer Elektrotechnik, v. 20, 1928, p. 162, by Tolwinsky and Hochberg (Leningrad) in a paper (German): "Asynchronous operation of a three phase induction machine with stator and rotor connected to the same supply system."

The information (theoretical developments and experimental results) contained in the German paper is supplemented by a few valuable remarks concerning the practical application of the principle involved. After pointing out the disadvantage of the low power factor at small loads, the Russian authors emphasize the fact that the superposition of a low-frequency current wave on the power supply system currents will be rather undesirable in so far as it will cause flickering of lights connected to the same system. As a consequence it must be feared that public utilities may prohibit application of said principle to motors connected to their power systems.

Very truly yours,
A. VAN NIEKERK (A'24)
(Designing Engr., Westinghouse Elec. & Mfg. Co.,
E. Pittsburgh, Pa.)

## Mechanical Analogs of Electric Circuits

*To the Editor:*

The use of electrical analogs for mechanical systems is based on definite analogies of form between the mathematical equations which describe the behavior of each type of system. The design of a mechanical phonograph (see "Methods of High Quality Recording and Reproducing of Speech and Music, Etc.," J. P. Maxfield and H. C. Harrison, *Bell Sys. Tech. Jl.*, v. 5, July 1926, p. 493) by electrical engineers some years ago apparently gave an impetus to the use of electrical analogs, although there has been comparatively little written on the subject. Skilling (see "Electric Analogs for Difficult Problems," H. H. Skilling, ELECTRICAL ENGINEERING, Nov. 1931, p. 862–5) has shown an application in a particular problem and has outlined some of the important advantages of the use of equivalent electric circuits.

The opposite process—use of mechanical analogs for electric circuits—does not appear to offer comparable advantages, particularly as far as circuit theory and ease in determining experimentally the action of a system are concerned. In certain cases, however, mechanical concepts may be of assistance to the electrical engineer. Several instances are cited below.

Consider Newton's Law of Motion

$$F = \frac{dG}{dt}$$

where

$F$ is the vector resultant of the forces acting on all the particles of a mechanical system

$G$ is the vector sum of the momenta of all the particles.

If $F = 0$, then $G$ is constant, which is the well-known law of the conservation of linear momentum.

The electrical analog of momentum (mass times velocity) is magnetic flux linkages (inductance times current) and the equivalent of the mechanical law is the electrical principle that in a circuit or group of circuits in which the resistance is small the flux linkages remain constant (approximately) when the forces (e.m.f.'s) are withdrawn, as on short circuit. (A capacitor gives rise to a force obeying Nooke's law in the electric-mechanical analogy.) This principle of electric circuits has not been very widely used, so that a comparatively recent writer (see "Short-Circuit Currents of Synchronous Machines," R. F. Franklin; A.I.E.E. TRANS. v. 44, 1925, p. 863–72) has felt it necessary to refer to a proof. That this analog of one of those laws of mechanics which are considered most fundamental is an electrical principle which has not been utilized by engineers for so very many years lends support to the thought that mechanical laws less prominent than the conservation of momentum may yet point out electrical principles of value in particular cases. The integral developed by Carson and applied by him to the analysis of electric circuits to which the usual circuit laws (Kirchoff's laws) were not readily applicable has been shown to have been used in equivalent mechanical form before electric circuits were known.

Experience indicates that most students, including those with some advanced training, consider work and kinetic and potential energies from the mechanical viewpoint, particularly when they understand the electric-mechanical analogy. Thus work is force times distance, hence e.m.f. times charge, while kinetic energy is $^1/_2\, mv^2$ for a particle, hence $^1/_2\, Li^2$ for a simple series circuit, etc. The magnetic energy is not always called kinetic energy, and the electric field energy is not always called potential energy, but it is of advantage to understand the analogy when for example the action of a system involving both electric and mechanical circuits such as a telephone receiver is analyzed. (See "Theory of Telephone Receivers," R. L. Wegel, A.I.E.E. JOURNAL, v. 40, 1921, p. 791–802. In this paper the total kinetic energy of an electromechanical system is set up and used in the Lagrangian equations to analyze the system.) The use of many advanced dynamical principles (Lagrange's equations for example), which are usually equally applicable to electric circuits, requires the setting up of expressions for the total kinetic and potential energies of the complete mechanical, electrical, or electromechanical system. It should be noted that the possibility of application of these mechanical principles to pure electric or electromechanical systems may be ascribed to the (formal) equivalence of mechanical for electric systems rather than vice versa.

Another conceivable case in which known mechanical principles might be used is in connection with the equilibrium and stability of an electromechanical system. The mechanical principles now available should suffice if need arises.

None of the above examples is very important in itself. They have been offered simply to illustrate some of the advantages to be derived from the consideration of mechanical "circuits" as analogs of electric circuits.

Very truly yours,
J. G. BRAINERD (A'32) (Moore School of Electrical Engineering, University of Pennsylvania, Philadelphia, Pa.)

## Junior Engineers Plan Industrial Projects

*To the Editor:*

The article "Junior Engineers Plan Industrial Projects" appearing in the July 1932 issue of ELECTRICAL ENGINEERING, p. 523, is of considerable interest.

The procedure of the program described in the article should be of interest to all members of the Institute Sections and Branches. There can be no doubt that the organization of the junior members within their respective local branches will produce an active continued interest among the young members.

The forming of these hypothetical companies and the solution of the problems involved should give the junior engineer an invaluable practical experience, as well as a chance to show his initiative and ability when confronted with a definite responsibility.

Local firms and public utility organizations, also elder members of these concerns or Institute Sections, should cooperate with the junior groups in offering their criticisms, suggestions, and experience.

This, then, is a very definite step in demonstrating to the junior engineer or graduate in what line of specialization he is more recommended, as well as forming a fraternal bond between the junior member and the profession.

Very truly yours,
HARRY A. ETKIN (A'26)
(520 McClellan St., Philadelphia, Pa.)

## Consumption, Production, Distribution

*To the Editor:*

In the progress report of American Engineering Council ("The Relation of Consumption, Production, Distribution," ELECTRICAL ENGINEERING, June 1932, p. 373–9), it seems to be assumed that savings have been too great. As a check on this theory I tried to secure the best data that I could find on the actual savings of the country, and have plotted the values in a curve, Fig. 1. This curve shows an estimate of the actual total volume of property, which is the actual measure of savings, as estimated by the U.S. Census and by the National Industrial Conference Board. I have corrected the figures for increase in population and for the change in the value of the dollar, giving the result in figures that are supposed to represent actual property, not dollars. It is plotted to a logarithmic scale so that the same slope of the curve indicates the same rate of increase at any point on the curve.

Of course the figures are not accurate. No one can tell just how much property you or I have, and no one can tell exactly the relative value of the dollar in times 50 years apart. But the figures are honest efforts to give comparable data, and the big differences shown leave us quite sure that they do represent a real change.

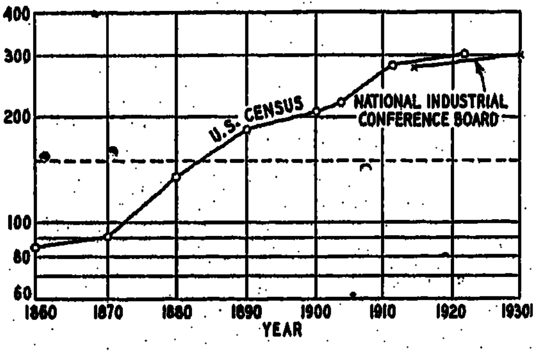


**Fig. 1. Per capita wealth of the United States expressed in index numbers. The scale is so selected that the slope of the line is the same at all positions if the per cent increase is the same**

First we see that the decade of the civil war was a time of slow increase in wealth, as would be expected. There was another slow rate of increase at the time of the 1893 depression, whether cause or effect is hard to tell. But the slowest rate of all has been the last few years. Unfortunately both recent figures include the period of the war, but the fact that both the latest figures of the census and the National Industrial Conference Board agree so closely would lead us to think that increase of wealth has not yet made its normal start, after the war.

Modern machines are expensive, and modern industry cannot operate without a greatly increased volume of capital. It is impossible to tell how much of the wealth shown by the curve is capital, but this failure of wealth to make a normal increase leads to the natural conclusion that capital has also failed to make its increase, and without this increase industry cannot function properly. This is merely one fact that supports the conclusion that one major cause of the present troubles is a shortage of capital. Therefore any method toward relieving the depression must be watched to see that it does not cause any further drain upon savings and capital. If it does it will probably cause more harm than good.

Very truly yours,
A. W. FORBES (A'12)
(Forbes & Meyers, Worcester, Mass.)

---

(Editor's Note: This letter is the second by Mr. Forbes discussing the economic problems covered in American Engineering Council's progress report.)

# Standards

## Wires and Cables

Three standards for wires and cables were approved by the American Standards Association on May 21, 1932, as follows: "American Standard Definitions and General Standards for Wires and Cables" (C8a-1932); "American Tentative Standard Specifications for Weatherproof (Weather Resisting) Wires and Cables" (C8k1-1932); "American Tentative Standard Specifications for Heat Resisting Wires and Cables" (C8k2-1932).

The first of these, the definitions and general standards for wires and cables, includes definitions and standards of a general character applicable to wires and cables for power purposes, and comprises a rearrangement of A.I.E.E. standard No. 30 of October, 1928, which has been brought up to date with certain additions and deletions. It contains definitions for the various types of wires and cables, conductivity standards, designation standards, high voltage test standards, insulation resistance standards, capacitance or electrostatic capacity standards, and maximum temperature limits.

The specifications for weatherproof wires and cables (C8k1-1932) cover weatherproof wiring and cables and the materials used for coverings and saturating compounds as applied to metallic conductors. The specifications are divided into the following headings: covering; saturating compound, which includes the tests therefore; stranded cables, including sizes of conductors and the stranding therefore; standard weights; a table of weights and weatherproof wires and cables; samples for tests; tests on copper conductors; and explanatory notes.

The specifications for heat resisting wires and cables (C8k2-1932) cover the usual type of heat resisting covering commonly known as "slow burning" as applied to metallic conductors for use in hot, dry locations where the other types of insulation would not long endure, or where the presence of large masses of inflammable materials would be objectionable. As explained in the standard itself, "There are many types of heat resisting materials used for insulating electrical conductors, but no attempt is made in this specification to cover anything but the so-called 'slow burning' insulation. The various types of asbestos coverings and enamels are for special purposes and are generally put out under trade names."

Printed copies of these documents on wires and cables will be available in the near future.

## Radio

Two new national standards for radio were approved by the American Standards Association on May 21, 1932, as follows: "Standard Vacuum Tube Base and Socket Dimensions" and "Manufacturing Standards Applying to Broadcast Receivers." These standards were developed by the sectional committee on radio working under the procedure of the American Standards Association, with the Institute of Radio Engineers and the A.I.E.E., the directing sponsors.

The first of the standards applies to certain details in the manufacture of broadcast receivers, which it is desirable to have uniform in the sets of all manufacturers; the second standard specifies dimensions for many of the principal types of bases and sockets of vacuum tubes used in both receiving and transmitting. The types of base covered in the standard are 4-pin bases of the large and small type; large 4-pin base without bayonet pin; large 5-pin base without bayonet pin; 4-pin transmitting tube base; large transmitting tube base: 4-pin sockets for receiving tubes; and 5-pin sockets for receiving tubes. The standard also specifies dimensions for terminal caps for both receiving and transmitting tubes and for connections between the tube elements and the pins.

The manufacturing standards applying to broadcast receivers establish a national standard for the frequency range of receivers from 550 kc. (545.1 m.) to 1,500 kc. (199.9 m.). The rating and design of socket-power devices and electric radio receivers are to be standardized for operation on from 105 to 125 volts. A standard test for quality of soldering of cord tips or terminals to radio cords also is provided. This test is a straight pull of 5 lb. applied to the cord tip or terminal. Other details for which standard dimensions are established are cord tips, binding posts, cable terminals, radio plugs and jacks, and pilot lamps. There also are standard definitions for the various parts of radio receivers. Information with regard to these standards may be obtained from the American Standards Association, 29 West 39th Street, New York, N. Y.

## Code for Protection Against Lightning

The sectional committee for the code for protection against lightning, working under the procedure of the American Standards Association and the sponsorship of the A.I.E.E. and the National Bureau of Standards, has completed a revision of parts I and II of the code. The original code was printed as "Miscellaneous Publication No. 92 of the Bureau of Standards," and information with regard to the proposed revision may be obtained from the chairman of the sectional committee, Dr. M. G. Lloyd, Bureau of Standards, Washington, D. C.

## Proposal Made for Emergency Lighting Code

The National Electrical Manufacturers Association has asked that consideration be given by the American Standards Association to the preparation of a code for emergency lighting. It states that for some time their codes and standards committee has been considering codes for lighting systems designed to insure adequate illumination for emergency use in such places as theaters, hospitals, schools, and other buildings. While there are many state and municipal codes governing such installations, there is little uniformity among them. At various times attempts have been made to incorporate rules governing these installations in the National Electrical Code and the National Electrical Safety Code. This proposal of N.E.M.A. now will go before the standards council of the American Standards Association.

## Test Code for Transformers

The standards committee of the Institute has asked that attention be called again to the "Test Code for Transformers." This code, which is the first of a proposed series of test codes covering electrical machinery and apparatus, has been out in its preliminary form for criticism and suggestion since October 1931.

In order to determine the performance characteristics of electrical machines, methods of testing have been developed and are in common usage. It is the purpose of these test codes to provide in convenient form the more generally applicable and accepted methods of conducting and reporting tests of a commercial nature and applying to the fulfilment of performance guarantees. In general the reception of this code has been favorable. Suggestions of a helpful nature have been received and the committee hopes this notice will result in a final clearing up of any debatable points so that publication in final form may be undertaken shortly. Copies of the preliminary report on the code may be obtained without charge. Address all communications to A.I.E.E. headquarters, 33 West 39th Street, New York, N. Y.

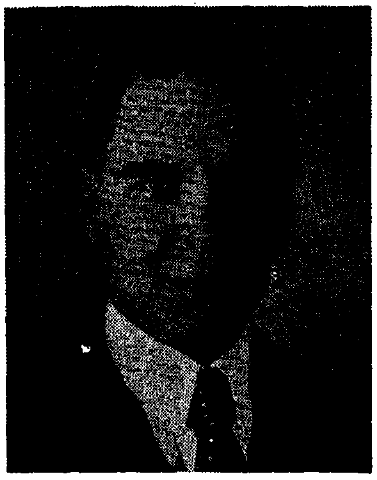
# Personal

Joseph Slepian (A'17, F'27) consulting research engineer of the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., upon June 12, 1932 received the John Scott Medal for his "discoveries in the field of the deionization of gases and fundamental and outstanding inventions involving these discoveries." This award carries with it besides the medal and certificate, a premium of $1,000 cash; it was presented to Doctor Slepian with due ceremonies at the Union League Club of Philadelphia. The award was established by John Scott, a chemist of Edinburgh, Scotland, who in 1816 bequeathed to the city of Philadelphia a fund of $4,000, the income from which was "to be distributed to ingenious men and women who make useful inventions...." After the fund had grown to $100,000 in 1917, court orders enlarged its use and specified that the premiums should be awarded "for inventions that will be useful to mankind in the development of chemical, medical, and any other science, or development of industry in any form; the test being that it may add to the comfort, welfare, and happiness of mankind." Doctor Slepian is a Bostonian by birth; his degrees of A.B., A.M., and Ph.D. were all won at Harvard University, the last one being conferred upon him in 1913, with mathematics his majoring subject. The winter of 1913 was given over to a semester at Göttingen University, Germany, and the following spring, to a semester at Sorbonne University, Paris, France. For a year he was instructor in mathematics at Cornell University, and in 1916 he joined the Westinghouse Company's East Pittsburgh force as an apprentice. His promotion to research engineer took place the following year, and in this and in a consulting capacity he has rendered exceptional service to his company. His conspicuous work upon circuit interrupting devices and his use of the unique principle of deionization in the destruction of powerful and violent electric arcs have been important contributions to the field of electric power transmission and distribution.

JOSEPH SLEPIAN

H. L. Wills (A'20) assistant to the vice-president, and also general manager, of the Georgia Power Company, Atlanta, Ga., participated in the A.I.E.E. 1931 national prize for best paper in engineering practise awarded the symposium on coordination of power and telephone plant, composed of 4 parts of which the paper, "Status of Joint Development and Research on Noise Frequency Induction," by Messrs. Wills and Blackwell was a part. Born in Burlington, Vt., he started an apprenticeship in the machinist's trade at the early age of 14. His next undertaking was in the capacity of transitman for the Wisconsin Central Railroad. By 1885 he was assistant to the operating engineer of the Schuyler Arc Light Plant, and from that time on over an extended period of years he continued to hold positions of increasing responsibility. In 1902 he joined the Georgia Railway and Electric Company, at Atlanta, to assume charge of the meter and maintenance repair shops, a service which he continued for 6 years. During the latter portion of his stay with this company, he was directing these 2 departments and also in charge of the contract department. His service as general manager of the Savannah Lighting Company was from 1908 until 1912, when he joined his present company, the Georgia Power Company, as district manager, with offices at Macon, Ga. Upon consolidation of his company with the Georgia Railway and Power Company, he was transferred to Atlanta, Ga., as special detail engineer. His long affiliation with the Georgia Power Company has included the various duties of resident engineer on the Tallulah Falls Development, rehabilitation of the underground distribution system at Atlanta, Ga., electrical engineer, electrical engineer and operating manager, and, since 1923, assistant to the vice-president as well as general manager, negotiating company relations with other wire using companies on problems of inductive interference. Mr. Wills has been particularly active in the National Electric Light Association, and has served on many of its committees. He is past-chairman of the A.I.E.E. Section at Atlanta, Ga., was its delegate to the fourth national radio convention, and a member of the subcommittee on legislation in 1925. His other memberships include the Institute of Radio Engineers, the International Association of Electrical Inspectors, the executive committee of which he served for 2 years; the American Engineering Council, and the Atlanta Chamber of Commerce. Mr. Wills was also a consultant with the committee on smoke prevention.

H. L. WILLS



W. S. PETERSON

O. B. BLACKWELL

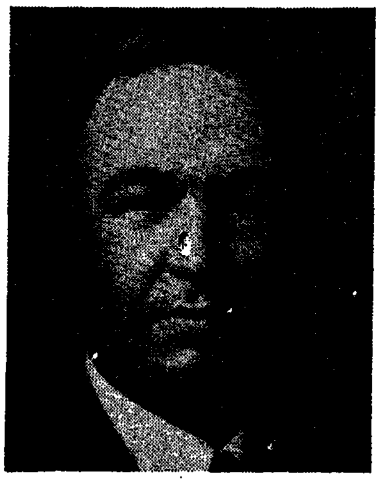
W. S. Peterson (A'23, M'29) transmission system engineer of the municipal water and power department, City of Los Angeles, Calif., has been awarded the 1931 A.I.E.E. Pacific District prize for best paper, the decision resting with his paper, "Calculation of Dynamic Power Limit of Transmission System During Three-Phase Faults." Mr Peterson was born at Anaconda, Mont. He entered upon an electrical engineering course at the University of California, Berkeley, Calif., and was graduated with the class of 1917 with his B.S. degree. He at once entered the test department of the General Electric Company at Schenectady, N. Y., remaining there until 1919, when he engaged with the Anaconda Copper Mining Company, Great Falls, Mont., for the operation and maintenance of substations. In September of 1922 Mr. Peterson started his work with the Los Angeles bureau of power and light, and in 1924 was transferred from the drafting room to the substation engineering department, his work including design of substations and writing of specifications. After a year of this work, he was advanced to research. Here his first work was the preparation of a report on the high voltage power system for the City of Los Angeles, which constituted the first step in the design of the system to receive the Colorado River power. Concurrently with this work, he was supervising the investigation of conductor movements during short circuits, the basis of a paper in joint authorship with H. J. McCracken, Jr. (A'27) and for which they received the 1927 national initial paper prize. Mr. Peterson also is serving as secretary of the technical committee of the bureau of power and light of the City of Los Angeles. His research work on the performance of insulators in dust and fog and also with regard to measurement of corona loss were carried on at the H. J. Ryan High Voltage Laboratory at Stanford University, in collaboration with Dr. J. S. Carroll (A'24) assistant professor of electrical engineering at Stanford University, and Bradley Cozzens (A'28) research engineer of the Department of Water and Power, City of Los Angeles.

O. B. Blackwell (A'08, F'17) now transmission development engineer of the American Telephone and Telegraph Company, New York, N. Y., shared in the 1931 A.I.E.E. national prize for best paper in engineering practise, for the paper which he prepared jointly with H. L. Wills (A'30) and which was entitled "Status of Joint Development and Research on Noise Frequency Induction," being an integral part of the symposium on coordination of power and telephone plant to which the prize was awarded.

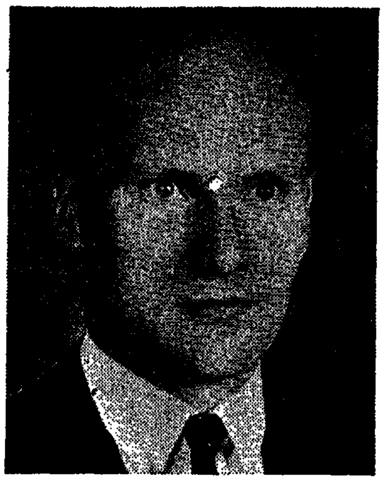
Mr. Blackwell who was born at Bourne, Mass., in 1906 received his B.S. degree from Massachusetts Institute of Technology. He at once entered the engineering department of the American Telephone and Telegraph Company, and in 1915 was placed in charge of transmission and protection, a subdivision of the department. Here he was given the supervision of some 40 technically trained men on important development and standardizing work of telephone transmission and protection circuits. By his collaborators Mr. Blackwell's work always has been recognized as uniformly of the highest grade—in fact it has won recognition for him throughout the entire telephone world. For a period of more than 7 years much of his work was looking toward the extension and betterment of telephone transmission through the use of loading coils, improved cable construction, telephone amplifiers, and similar electrical equipment. Illustrative of his work is the design of a standard transposition system for lines carrying phantom circuits, important work on the development of duplex telephone cables, and contributions of great importance to the successful use of telephone repeaters on long lines. He is a Fellow of the Institute of Radio Engineers and of The Acoustical Society of America; he also holds membership in the Machinery Club of New York City, the Manhassett Bay Yacht Club, and the North Hempstead Country Club.

H. L. Huber (M'23) engineer on foreign wire relations, American Telephone and Telegraph Company, New York, N. Y., who prepared the paper, "Status of Cooperative Work on Joint Use of Poles," in joint authorship with J. C. Martin (A'12) participates in the 1931 A.I.E.E. national prize for best paper in engineering practise, which has been awarded the symposium on coordination of power and telephone plant. Mr. Huber is a native of the state of Colorado, and a graduate of Mercersburg Academy and Cornell University. In 1913 he became plant engineering inspector for The Chesapeake and Potomac Telephone Company, Washington, D. C., designing its outside plant, preparing estimates, writing specifications, and doing construction work. In 1915 he became engineering assistant in the company's general engineering department, checking high tension line construction at crossings, and studying inductive interference and mechanical problems in connection with telephone line construction. In 1917 he was made district plant engineer in charge of laying out the outside telephone plant at Camp Meade and the Aberdeen Proving Grounds. December of that year he joined the U.S.

Signal Corps, and for the last half of 1918 as 1st lieutenant, was locating long distance telephone pole lines in France. In July 1919 he was back in the United States as division plant engineer in West Virginia for The Chesapeake and Potomac Telephone Company, and associated companies in charge of planning, estimating, and writing specifications. The next year he became engineering assistant in the company's general engineering department, which office he continued to hold until 1925 when he was made appraisal engineer. His history with the American Telephone and Telegraph Company dates from 1927.



H. L. HUBER



ERNST WEBER

L. V. BEWLEY

**Ernst Weber** (A'31) visiting professor of electrical engineering, Polytechnic Institute of Brooklyn, N. Y., has been awarded the 1931 A.I.E.E. national prize for initial paper, for his paper "Field Transients in Magnetic Systems." Doctor Weber was born at Vienna, Austria, and received his diploma as engineer from the Technical University in Vienna, April 1924; 2 years later his Ph.D. was conferred upon him by the same institution. In 1929 he earned what is termed "Privat dozent" (extraordinary professorship) at the Technical University at Berlin-Charlottenburg in the department of electrical engineering. After graduating in 1924 he was research engineer for Oesterreichische Siemens-Schuckert-Werke at Vienna in the department of electrical machine design. He then went with the Siemens-Schuckert-Werke in Berlin as research engineer in the electrical machinery department and continued there until 1930 when he came to the United States. Here he took up his present work at the Polytechnic Institute of Brooklyn in postgraduate lectures on electromagnetic theory, advanced circuit theory, and conformal mapping of high voltage problems. In September of 1931 he was made research professor of electrical engineering, still continuing with postgraduate lecturing, adding "higher mathematical analysis and its application" to his other subjects of discourse.

Doctor Weber is a member of the Viennese Institute of Electrical Engineers (1923); the Berlin Society of Applied Mathematics and Mechanics (1929) and Institute of Electrical Engineers (Germany) (1930). Only recently has become a member of the American Physical Society. He has been an abundant contributor to technical literature both here and abroad.

**L. V. Bewley** (A'27) of the power transformer department, General Electric Company, Pittsfield, Mass., has been awarded the 1931 A.I.E.E. national prize for best paper in theory and research, for his paper "Transient Oscillations in Distributed Circuits With Special Reference to Transformer Windings." Born at Republic, Wash., Mr. Bewley attended grade and high schools at Boise, Idaho. During the war, he left high school to serve as a machine gunner, spending 19 months out of the 28 he was in service, in France. Upon his return to the United States he entered the University of Washington and in 1923 received his B.S. in E.E. He joined the General Electric Company's test course, its 3-year advanced course in engineering, and the Union College G.E. cooperative course, receiving from the latter in 1927, his M.S. degree. Mr. Bewley's work has included design of induction motors, high-voltage bushings, synchronous converters, a-c. generators and motors, coupling capacitors, and power transformers. For the past few years he has been engaged with special problems of semi-theoretical and mathematical nature, and for the past 6 years in the General Electric evening courses he has taught advanced circuit theory (Maxwell, Heaviside, symmetrical components, system stability, etc.). He has contributed liberally to the Institute's literature, both with regard to technical papers and active discussion. He still holds a captaincy in the U.S. Engineers Reserve Corps.

**V. A. Hoover** (A'32) has received the 1931 A.I.E.E. Pacific District prize for initial paper, the decision being based upon the high quality of his paper entitled "Correlation of Induction Motor Design Factors." At the present time Mr. Hoover is engaged in the duties of a research assistant at the California Institute of Technology, where he is associated with Dr. S. J. Barnett, professor of physics, in special work on the nature of the elementary magnet in cobalt and nickel alloys. Under Dr. R. W. **Sorensen** (A'07, F'19) he also has been a teaching fellow in the institution's department of electrical engineering. His Ph.D degree was conferred upon him by California Institute of Technology in 1931 upon the completion of a course in electrical engineering, physics, and mathematics, the culmination of an 8-year period of work, undergraduate and graduate. Mr. Hoover has acquainted himself with the practical side of the profession also by summer work with the Southern California Edison Company, Ltd., at Los Angeles, Calif., where his duties were in connection with substations and meter testing, and by a part-time service with the U. S. Electrical Manufacturing Company of Los Angeles, as motor designer. His native city is Leadville, Colo.

**E. W. Palmrose** (A'32) who for his paper "Vacuum Tube Voltage Regulators" has received the 1931 A.I.E.E. Pacific District prize for Branch paper, was born in Finland. Upon graduation from the University of California, Berkeley, Calif., May 1931, he received his B.S. in E.E. His first practical work was as an apprentice machinist in the shops of the Hammond Lumber Company, Samoa, Calif.; this occupied him from 1925 to 1928, when after a brief interim he became connected with the Pacific Telephone and Telegraph Company, at Eureka, Calif. His position as draftsman with the Southern Pacific Golden Gate Ferries, Ltd., San Francisco, Calif., dates from late in 1929, on part time until his graduation from the university in May 1931, and full time beginning with June of that year; present activities include repairs to slips and wharves, the design of hydraulic bridge lifting machinery, parts for Diesel engines, steam condensers, and electric steering gear indicators for Diesel-electric ferries. The paper for which Mr. Palmrose was awarded the 1931 A.I.E.E. Pacific District prize for Branch paper was based upon the thesis prepared for his degree of B.S. in E.E.

**N. R. Damon** (Enrolled Student) University of Colorado, Boulder, Colo., and coauthor of the paper "New Ideas for High Voltage Circuit Breakers" shares with C. A. **Church** (Enrolled Student) in the award of the 1931 A.I.E.E. North Central District prize for Branch paper. Mr. Damon is a native of Hollenberg, Kans. He received his high school education at Laporte and Cheyenne Wells, Colo., and his technical training at the University of Colorado, from which he was graduated June 1931 with the degree of B.S. in E.E. His work at the present time is in graduate study and research at the University of Colorado, prerequisite to his master's degree in electrical engineering June 1932. Mr. Damon and Mr. Church are also fraternity brothers in Tau Beta Pi, Eta Kappa Nu, and Sigma Xi.

**J. S. Brown** (A'23, M'31) who was formerly engineer in the electrical division of the Stone and Webster Corporation, Boston, Mass., and still earlier identified with engineering projects of the firm of McClellan and Junkersfeld, Inc., and also that of Dwight P. Robinson Company, New York City, in responsible charge as electrical engineer, assistant superintendent of construction in charge of field forces, and electrical construction superintendent, now has tentatively entered upon a consulting engineering practise of his own in electrical and industrial fields, at Petersburg, Va.

E. B. Crane (A'23) previously with the Ohio Edison Company's Youngstown office as assistant engineer, effective June 1, 1932, was transferred to its central engineering department at Akron, a recently created division for the coordination and standardization in engineering design, practise, and materials.

R. H. Park (A'27), until recently an electrical engineer with the Stone and Webster Engineering Corporation, Boston, Mass., is now affiliated with the Calco Chemical Company of Bound Brook, N. J., where he is engaged in research in mathematical physics and the design of equipment. Mr. Park's work with Stone and Webster included design and operating problems in connection with various plant, structure, and equipment projects handled by that concern, particularly in connection with special analyses.

A. E. Kennelly (A'88, F'13, and past-president) professor emeritus of electrical engineering at Harvard University, Cambridge, Mass., on July 6, 1932, at a meeting in Paris, France, was chosen vice-president of the International Electrical Congress which convened there July 4-12, and at which approximately 1,300 delegates of 11 nations discussed from the angle of pure science electrical subjects of the day.

S. P. Grace (A'03, F'21) assistant vice-president of the Bell Telephone Laboratories, Inc., recently received from the University of Michigan the honorary degree of Doctor of Engineering, and from Notre Dame the honorary degree of Doctor of Laws. (The announcement in Electrical Engineering, July 1932, p. 530, did not state that the University of Michigan degree was an honorary degree.)

W. D'A. Ryan (A'02) who has been serving the General Electric Company of Schenectady, N. Y., as director of its illuminating engineering laboratory, recently was named consulting engineer of the company's lighting section.

R. A. Krasovec (A'31) whose work during the last several years has been that of chief electrician, U.S. Army Post, Mitchell Field, New York, N. Y.; electrician D. L. & W. Railroad, Hoboken, N. J., and of the New York Central Railroad, Cleveland, Ohio; chief electrician of the Lackawanna Anthracite Coal Mining Company, Vandling, Pa., and from 1929-31, electrical foreman of the Andes Copper Mining Company, Chanaral, Chile, S. A., now has joined the Corte Engineering Company of New York City, as sales engineer.

W. M. Williams (A'25) who has been serving Roth Brothers Company of Chicago, Ill., as electrical engineer, recently joined the Century Electric Company of St. Louis, Mo.

A. A. Schuhler (A'19, M'27) who recently was sales engineer for the Connecticut Telephone and Electric Corporation, at Meriden, Conn., now is chief sales engineer of Stanley and Patterson, Inc., New York, N. Y.

C. E. White (A'30) previously located at Salt Lake City, Utah, and at one time identified with the General Electric Company's general test work on electrical machinery, and with transformer engineering design, now has joined the Ohmite Manufacturing Company of Chicago, Ill., as electrical design and production engineer. Mr. White is past-chairman of the A.I.E.E. Student Branch at the University of Utah, and past-assistant secretary of the Institute's Fort Wayne Section.

W. B. Hopkins (M'20) who for the past 2 years has served the Stone and Webster Engineering Corporation of New York, N. Y., as a vice-president, engineering manager, and a director, has tendered his resignation, effective June 30, 1932.

C. L. Fortescue (A'03, F'21) who is consulting transmission engineer for the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., and a frequent contributor to A.I.E.E. technical literature, in both papers and discussion, has been chosen by The Franklin Institute to receive the Elliott Cresson Medal, for "his work in presenting theory and application of symmetrical components for studying balanced and unbalanced a-c. circuits," the subject of a paper which he recently presented at a statistical meeting of The Franklin Institute, Philadelphia, Pa.

H. C. Forbes (A'25, M'30) who for the past 5 years has been research engineer in the electrical engineering department of the New York Edison Company, New York, N. Y., recently was appointed system engineer. Mr. Forbes' history with the company dates from 1924 when he joined the electrical engineering department as assistant to the chief electrical engineer.

W. B. Campbell (A'30) who for the past year or so has been serving the Delta Star Electric Company, Chicago, Ill., as assistant engineer, now is assistant curator of motive power at the Museum of Science and Industry in Chicago.

C. W. Adams (A'20) formerly manager of the carbon products division of the United States Graphite Company, of Saginaw, Mich., is now with the California Public Service Company, as its division manager at Fort Bragg, Calif.

A. C. Bates (A'31) who was research assistant at Purdue University, West Lafayette, Ind., now is identified with the University of Pennsylvania at Philadelphia, Pa., as instructor in the department of mechanical engineering.

K. W. Jarvis (A'25) who was radio engineer of the United States Radio and Television Corporation, at Marion, Ind., and who has served the Institute of Radio Engineers on several of its committees, now is assistant chief engineer of the Zenith Radio Corporation in Chicago, Ill.

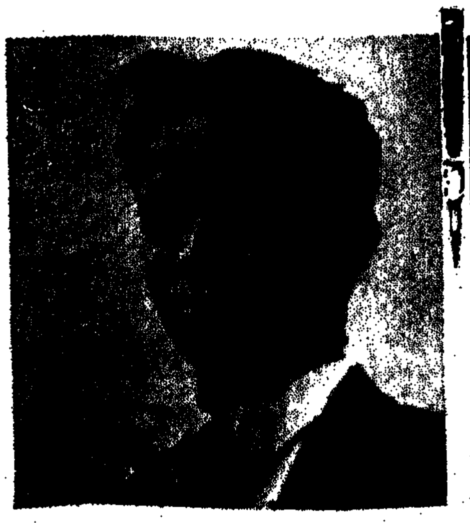
C. F. Hirshfeld (A'05) chief of Detroit Edison Company's research department and a manager of The American Society of Mechanical Engineers, recently was honored with the degree of Doctor of Engineering by Rensselaer Polytechnic Institute, Troy, N. Y.

J. L. McQuarrie (A'07, F'26) who has been serving the International Telephone and Telegraph Company, New York, N. Y., as a vice-president and chief engineer, has tendered his resignation and will retire from these connections.

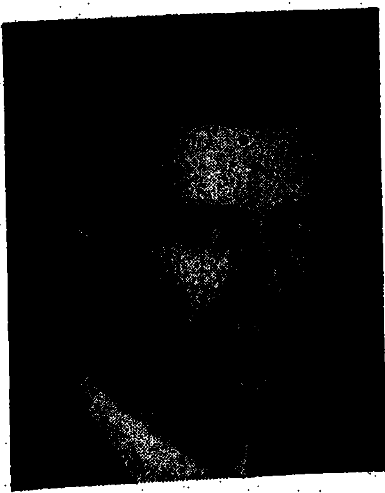
Gerard Swope (A'99, F'22) president of the General Electric Company, New York, N. Y., was given the degree of Doctor of Science recently by Washington University, at St. Louis, Mo., his native city.

F. A. Rogers (A'06, M'28) professor of physics and electrical engineering at Lewis Institute of Technology, Chicago, Ill., has been appointed dean of its engineering faculty.

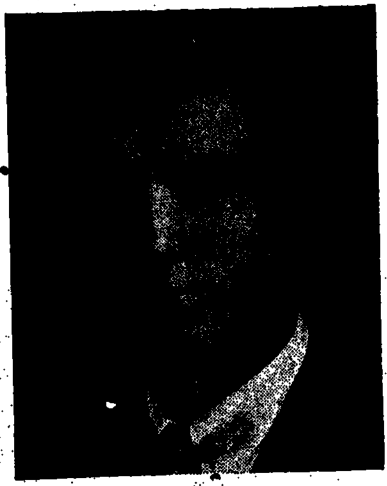
A. J. Smith (A'22, M'29) who has been serving the General Water Works and Electrical Corporation, New York, N. Y.,



V. A. HOOVER



E. W. PALMROSE



W. R. DAMON

as vice-president now has opened a consulting engineering office in Vancouver, B. C., Can.

C. A. Robinson (A'11, F'22) who prior to becoming assistant vice-president of the Chesapeake and Potomac Telephone Company was its chief engineer, recently was given the new office of general manager. His headquarters will be at Charleston, W. Va. For one year (1926–27) Mr. Robinson was chairman of the Institute's Washington (D. C.) Section, and for 2 years (1927–29) was a member of its communication committee.

Rolf Alvung (A'25) previously associated with the Standard Steel Car Company, Hammond, Ind., as an electrical engineer, now is with the Chicago Great Western Railroad, Chicago, Ill., in like capacity.

R. A. Connor (A'17) for the past year has been Pacific Coast manager of the National Electric Products, Inca manufacturing division, Los Angeles, Calif.; now he is western manager of the Phelps Dodge Copper Products Corp., Inca manufacturing division, in the same city.

P. de G. Baldwin (A'31) who last year was serving the RCA Photophone Inc., of Philadelphia, Pa., as installation and service engineer now is broadcast engineer of the WALR radio station at Zanesville, Ohio.

Newton Jackson (A'14, M'17) electrical engineer for the Virginia Public Service Company, at Charlottesville, Va., has been transferred to the company's office at Alexandria, Va.

F. I. Lawson (A'22) assistant engineer of the division of hydroelectric and transmission engineering of the Pacific Gas and Electric Company, San Francisco, Calif., recently joined that company's bureau of tests at Emeryville, Calif.

H. H. Cox (A'08, M'27) of the department of water and power, Los Angeles, Calif., has been appointed to the executive committee of the Los Angeles Electric Club for the year 1932–33.

F. J. Bartholomew (A'26) president of Electric Power Equipment, Ltd., Vancouver, B. C., is a director of the Vancouver Electric Club, for the current term of service.

J. D. Ross (A'08, F'12) has recently received his reappointment to the office of superintendent of the city light department, Seattle, Wash., a service which he already has rendered that city over an extended period during consecutive years.

S. E. Doane (A'89, F'12) consulting engineer, New York, N. Y., has received election as a vice-president of A. F. Hatch and Company, Inc., New York, N. Y., a reorganizing and refinancing body for firms in distress.

# Obituary

William Wolcott Tefft (M'26) consulting engineer of Jackson, Mich., died on June 24, 1932, at the Doctor Cowie private hospital in Ann Arbor, Mich. Mr. Tefft had for many years been prominent in the power activities of Michigan and surrounding states, and many of the outstanding developments of this region are credited to him. He was born at Milbank, S. D., in 1882, receiving his B.S. in C.E. in 1907 from the University of Michigan; in 1930 he received the honorary degree of doctor of civil engineering from the same institution. In 1910 he married Ethel L. Foote, daughter of W. A. Foote, who with his brother founded the Consumers Power Company. He began his professional career in 1902, spending summers as a rodman with surveying parties in electric railway construction, and later engaged in federal water power surveys until 1906. 1907–8 found him as resident engineer for the construction of a hydroelectric plant at Superior, Mich. His first connection with the Fargo Engineering Company, Jackson, Mich., was in 1908; here he continued as a member of the firm until 1919, having complete supervision of work on a large number of dams, many of them important plants on what is now the system of the Consumers Power Company. During this period he invented the Tefft conduit spillway which is claimed to reduce hydroelectric construction costs in some instances as much as 42 per cent. During the World War he investigated and reported to the government on water power possibilities in Michigan and Wisconsin. Continuing with offices in Jackson, he was consulting hydraulic and civil engineer for Hodenpyl, Hardy and Company between 1919 and 1924, and from this latter date until 1928 was vice-president and chief engineer of the Commonwealth Power Corporation and subsidiary companies, including the Consumers Power Company. In 1928 he entered private practise as a consulting engineer and in 1929 rejoined the Fargo Engineering Company as vice-president, in which office he continued until his death. Since 1930 he has been also president of the General Power Corporation. Mr. Tefft was the author of many technical articles, and a member of the American Society of Civil Engineers, The American Society of Mechanical Engineers, Michigan Engineering Society (director), National Electric Light Association, the American Society of Military Engineers, the American Society for the Advancement of Science, and American Men of Science. He was a member of the American committee to the World Power Conference, and was president of the board of trustees of Albion (Mich.) College. He was honored in 1929 by membership in Sigma Xi "for accomplishments in hydraulic engineering." Mr. Tefft has been active in church work. The clubs of which he was a member include the Rotary, Torch, Jackson City, Jackson Country, Jackson Gun, and the Bras Coupe Hunting and Fishing Clubs.

Robert Baird Williamson (A'02, F'12) for many years in charge of the Allis-Chalmers Manufacturing Company's division on a-c. rotating machinery, at Milwaukee, Wis., died June 26, 1932. Mr. Williamson, who was born at Smith's Falls, Ontario, Can., 59 years ago, was graduated from Cornell University, Ithaca, N. Y., in 1893. Two years of electrical construction work was followed by 2 years as chief draftsman for the Canadian General Electric Company. During the 3 years following 1897, while serving as an instructor in electrical engineering at Lehigh University, Bethlehem, Pa., the textbook "Alternating Currents" was written with Prof. W. S. Franklin as coauthor. This book for a score of years was standard in leading engineering colleges. From 1899 to 1905 Mr. Williamson served as principal of the electrical engineering department of the International Correspondence Schools. In 1905 he joined the Norwood, Ohio, plant of the Allis-Chalmers organization. His manner was quiet and unassuming and one which would inspire confidence immediately. The 27 years during which he was a member of the engineering staff of the Allis-Chalmers Manufacturing Company included a period of great expansion in the electrical industry, marked by the adoption of machinery of ever increasing size; many machines designed under Mr. Williamson's supervision have established world's records for size and efficiency. He has been a frequent contributor to A.I.E.E. literature, has served on the board of managers and as a member of the following technical committees: industrial and domestic power (1916–20); iron and steel industry (1916–20); power stations (1919–24); standards (1916–22); U.S. National committee of the International Electrotechnical Commission (1919–27); Edison Medal (1921–23); electrical machinery (1921–32); and the Lamme Medal committee (1930–32). He also served as the Institute's representative on American Engineering Council (1924–25). Mr. Williamson was a member of the honorary scientific fraternity, Sigma Xi, the Engineers Society of Milwaukee, the University Club, Westmoor Country Club, and a trustee of the Milwaukee Calvary Presbyterian Church.

Basil Condon Battye (M'21) the A.I.E.E.'s local honorary secretary for India with headquarters at Lahore, and chief engineer of the hydroelectric branch of the Punjab Public Works Department, was killed in a motor accident which occurred May 16, 1932, near Batala, district of Gurdaspur, India. Although born in Punjab, Colonel Battye received practically all of his schooling in the various preparatory institutions and colleges of Great Britain; this included a year at the Royal Military Academy at Woolwich, and a year and a half at the School of Military Engineering, at Chatham, England. In 1903 at the age of 21 he became a lieutenant in the 53rd Railway Company of Royal Engineers, the next year advancing to military assistant field engineer. In 1908 still in the English army, but working in a civilian capacity, he took what was termed "specialist training" with various firms in

England. Again returning to the strictly military field, he became officiating supervising electrical engineer of the Military Works Department, with headquarters at Simla, India. Following this he served as deputy assistant director general also at Simla military headquarters. From 1910 to 1914 his government loaned him to the Punjab Public Works Department, where, as engineer-in-charge, he designed, constructed, and operated the Simla hydroelectric and water works extensions. This work was followed by a tour of Switzerland for the purpose of inspecting all hydroelectric plants of importance in that country. November 1914 he was in command of the 21st Company, 3rd Sappers and Miners, of the Lahore Division in France; here he organized the trench searchlight service. He was wounded in the early part of 1915, but upon recuperation returned to action and became field engineer of the Lahore Division, later in that same year being made general staff officer, 3rd to 1st grade. In 1917 he became assistant engineer-in-chief, general headquarters, in charge of the forward transportation department; in 1918, chief engineer, G. H. Q. defence scheme; and later that same year, general staff officer, 1st grade, 34th Division. During the war he was 7 times mentioned in military dispatches to England and in 1916 received the D. S. O. Upon return to civilian life in 1919 he became engineer-in-charge of the Sutlej River hydroelectric project, then under investigation, with surveys to complete and design and estimates to prepare. His connection with the Punjab public works department took him out upon many missions of design and construction. It was while on a company errand that he was fatally injured in a motor crash. He was an associate member of the British Institution of Civil Engineers and the Institution of Electrical Engineers, and also of the American Society of Civil Engineers.

Archibald Johnson Robertson (A'16) substation manager for the Mt. Whitney division of the Southern California Edison Company, Ltd., at Visalia, Calif., died suddenly June 13, 1932, in that city. Born in Cleveland, Ga., September 19, 1876, he spent the period 1894–98 in attendance at Georgia School of Technology at Atlanta. His first commercial work was with the Fulton Bag and Cotton Mills in that city; but he remained with these interests for less than a year and in 1899 joined the Hardy Tyne Manufacturing Company at Birmingham, Ala. Later in the same year he became operator of various hydroelectric plants of the Mt. Whitney Power and Electric Company (subsequently a unit of the Edison system). His affiliation with this company continued unbroken up to the time of his death.

Henry Lyles Zabriskie (A'03) who has been serving the Diehl Manufacturing Company, of Elizabethport, N. J., as chief engineer, died the evening of July 10, 1932. He was born in New Baltimore, N. Y., January 26, 1877; from Cornell University, in 1898, he won his degree of M.E. in E.E. This, however, was 2 years subsequent to his first practical professional work when he served the Excelsior Electric Company of Brooklyn, N. Y., in its drafting and testing departments. For a short period he was with the Fort Wayne Electric Company (Indiana), as assistant to the electrical engineer, and upon leaving this company in 1899, he became assistant electrical engineer for the Siemens and Halske Electric Company, of Chicago, Ill. Here he remained until late in the year 1900, when he joined the New York Transportation Company, New York, N. Y., first in its electrical engineering department, and later becoming treasurer. His record with the Diehl Manufacturing Company covers a period of more than 25 years, always in the office of chief engineer. He was a member of the Institute's electrical machinery committee 1926–27, 1928–31.

Richmond Talbot (A'02 and Life Member) who has been a member of the firm of Sanderson and Porter, an engineering concern of New York City, died at his home in Tuxedo, N. Y., May 26, 1932. He was 59 years of age and a native of New York City. After a primary education obtained in the Cutler private school of New York City, Mr. Talbot attended the Philips Exeter Academy, later graduating from Harvard University with the class of 1896. For about a year thereafter he was associated with the Marsh Plate Glass Company of Pittsburgh, Pa.; then he returned to New York City to become a member of the firm of Sanderson and Porter, at that time active in electric lighting and railway design, construction, and operation; hydraulic development, and transmission. In 1899 in addition to his duties with Sanderson and Porter, he took over the general managership of the Tuxedo Electric Light Company, at Tuxedo, N. Y., his place of residence. In his Sanderson and Porter affiliation he was associated with many important public utility and industrial activities organized and built up by his firm, and with their management and operation. His social clubs included the Union, Racquet and Tennis, New York Yacht, City Midday, Harvard (N. Y.), St. Nicholas Society, Tuxedo, and the Harvard Club of Boston.

Frank Haye (A'31) electrical mechanic of the Industrial Electric Motor and Tool Company, Inc., New York, N. Y., died suddenly June 9, 1932, in New York, N. Y., of heart failure. He was born in Tettnang, Germany, March 8, 1903. He attended a trade school, studying electrical engineering, in Munich, becoming an electrical mechanic. From 1917 to 1920 he served an apprenticeship in his native town; then early in 1921 he engaged as mechanic with a firm in Friedrichshafen, Germany. This experience which was of short duration was followed by 2 years as electrician helper for a number of local business interests in Munich, Germany. The first of the year 1923 found him engaged as electrical mechanic for Mittlere Jsar A. G., Munich, where he remained until the fall of 1924 when he became salesman of tools, for commercial interests at Koenigsberg e. P. The following fall he went to Stockholm, Sweden, as electrician for Wenlenhoffs Elektriska Aktiebolag, serving in this capacity with this and another firm until March 1927 when he came to the United States and engaged with the company with which he was connected at the time of his death.

# Local Meetings

## District No. 6 Holds Annual Student Conference

In attendance at the sixth annual conference of student branches held by the Institute's North Central District (No. 6) April 15 and 16, 1932, at the University of Denver, Denver, Colo., were 73 members, delegates and other interested parties, most of whom took part in the many active discussions. Two sessions of the conference were held, one Friday afternoon, and one Saturday morning, both presided over by District Vice-President P. H. Patton of Omaha, Neb. Friday evening, April 15, the delegates to the conference were guests of the Denver Section at dinner, following which Dr. Charles A. Lory, president of the Colorado State Agricultural College, Ft. Collins, addressed the group on the subject of "Rural Electrification," a subject of local and timely interest which aroused extensive discussion. At the Friday afternoon session, the following papers were presented:

Detailed Report on the 1931 Annual Summer Convention, by H. F. Rice, student counselor, University of North Dakota Branch, and M. S. Coover, secretary District No. 6.

Observations on the Success and Failure of Engineering Graduates, by R. B. Bonney, educational director, Mountain States Telephone and Telegraph Company, Denver, and A. H. Heitzler, superintendent, electric department, Public Service Company of Colorado, Denver (two papers).

The Importance of a good Command of English in the Life of the Engineer, by P. H. Patton, District vice-president.

What Should Be the Place of the Engineer in Present Day Life?, by W. C. DuVall, student counselor, University of Colorado Branch.

The Saturday morning session was opened by an address by Dr. W. D. Engle, vice-chancellor of the University of Denver, who voiced the official welcome to the delegates to the conference. Presented at the

Saturday morning session were the following papers.

What Should Be the Place of the Engineer in Present Day Life? by H. S. Rush, student counselor, North Dakota Agricultural College Branch, and W. M. Ely, chairman, University of Nebraska Branch (two papers).

How Can the Branch Aid in Developing Personality and Leadership Among Its Members? by C. W. Caldwell, counselor, University of South Dakota Branch, F. W. Cooper, chairman, University of Colorado Branch, and L. J. Schwehr, chairman, North Dakota Agricultural College Branch (three papers).

How Can the Branch Aid the High School Senior and the College Freshman to Determine His Adaptability for an Engineering Career? by L. C. Trussler, chairman, University of Denver Branch, A. J. Redmann, chairman, University of North Dakota Branch, and H. L. Fry, chairman, South Dakota State School of Mines Branch (three papers).

Should Engineering Schools Modify Their Curricula to Better Meet Present Day Economic Conditions? by G. H. Sechrist, counselor, University of Wyoming Branch, and J. O. Kammerman, counselor, South Dakota State School of Mines Branch (two papers).

To What Extent Should Students Be Urged to Become Members of the A.I.E.E.? by F. W. Norris, counselor, University of Nebraska Branch, L. Johnson, chairman, University of South Dakota Branch, and N. H. Sanders, chairman, University of Wyoming Branch (three papers).

The conference took action on the question of the seventh annual District conference, assigning it to the South Dakota State School of Mines, Rapid City, S. Dak., for the spring of 1933. Conference action also included the election of Prof. H. S. Rush, counselor of the North Dakota Agricultural College Branch, as chairman of the committee on student activities for the North Central District, to succeed Prof. H. F. Rice, counselor of the University of North Dakota. Professor Rush attended the annual summer convention at Cleveland in June 1932 as the counselor delegate from District No. 6.

Analysis of the attendance of the District conference is as follows:

| | |
|---|---|
| District officers | 2 |
| Student counselors | 8 |
| Branch chairmen | 8 |
| Students, Colo. State Teachers College | 3 |
| Students, Univ. of Denver | 4 |
| Students, Univ. of Colo. | 4 |
| Mountain States Tel. & Tel. Co. | 8 |
| Public Service Co. of Colo. | 16 |
| General Electric Co. | 4 |
| Colo. Agricultural College | 2 |
| Univ. of Colo. | 3 |
| Univ. of Denver | 2 |
| Consulting engineers and others | 9 |
| Total | 73 |

## Past Section Meetings

**Atlanta**

Functions of a Public Service Commission, by James A. Perry, Georgia Pub. Serv. Commission. June 6. Att. 230.

**Boston**

Annual meeting. Election of officers: F. D. Hallock, chmn.; W. H. Timbie, vice-chmn.; G. J. Crowdes, secy.-treas. May 17. Att. 120.

**Cincinnati**

Joint meeting with the Univ. of Cincinnati Branch. The following papers presented by students: Design and Construction of a Laboratory Arc Furnace, by E. J. Emmerling; Measurement of Modulation, by J. Epstein; Measurement of Radiation, by C. L. Ramsey; Constant Radio Frequency, by A. C. Hereweh. May 12. Att. 140.

**Columbus**

Astronomy and Human Affairs, by Prof. H. T. Stetson, Ohio Wesleyan Univ. Election of officers: K. Y. Tang, chmn.; Roy Mallory, vice-chmn.; H. L. Willson, secy.-treas. June 3. Att. 30.

**Detroit-Ann Arbor**

Election of officers: O. E. Hauser, chmn.; J. R. North, vice-chmn.; R. Foulkrod, secy.-treas. Golf and dinner. June 18. Att. 43.

**Houston**

Election of officers: James B. Arthur, chmn.; P. H. Robinson, secy.-treas. Dinner. May 31. Att. 81.

**Ithaca**

Teletypewriter Systems, by B. K. Boyce, N. Y. Tel. Co. April 22. Att. 160.

Election of officers: W. E. Meserve, chmn.; B. K. Northrop, secy.-treas. June 3.

**Louisville**

Business and recreational meeting. Election of officers: C. M. Ewing, chmn.; L. O. Adams, secy.-treas. June 17. Att. 72.

**Memphis**

Inspection trip through the Memphis Pwr. and Lt. Co. June 21. Att. 55.

**Mexico**

Outlook of Railroad Electrification in Mexico, by P. Gomez Pena, Natl. Rys. of Mexico. Dinner. June 16. Att. 36.

**Minnesota**

Annual dinner dance. Election of officers: H. J. Pierce, chmn.; E. H. Hagensick, vice-chmn.; R. R. Herrmann, secy.-treas. June 3. Att. 88.

**San Antonio**

Organization and Cooperation vs. Individual Ability, by M. C. Johnson, J. C. Penny Co. Dinner. May 28. Att. 57.

**San Francisco**

Adventures in Science, by Ellis L. Manning, Genl. Elec. Co. Dinner. May 31. Att. 1150.

**Sharon**

Ultra Violet and Its Application, by G. W. Keown, Westinghouse Lamp Co. Film—"Hydro Electric Power Development in the New South." June 14. Att. 98.

**Spokane**

History of the Electrical Development of the Inland Empire, by John B. Fisken, Washington Water Pwr. Co. May 26. Att. 14.

**Toledo**

Research as a Tool of Industry, by Dr. W. E. Wickenden, Case Sch. of Applied Science. April 5. Att. 700.

Problems in Designing of Large Alternating Current Generators, by S. H. Mortensen, Allis-Chalmers Mfg. Co. Illus. April 15. Att. 28.

Application of Electricity in Industry, by Ralph Paxton, Toledo Edison Co. May 20. Att. 30.

Modern Engineering Achievements, by C. L. Proctor, Toledo Edison Co.; Humaneering, by S. K. Mahon, Toledo Edison Co. Election of officers: I. H. Heitkamp, chmn.; E. H. Howell, vice-chmn.; W. M. Campbell, secy.-treas. June 15. Att. 28.

**Urbana**

Election of officers: E. A. Reid, chmn.; H. N. Hayward, vice-chmn.; L. L. Smith, secy. May 16. Att. 14.

**Vancouver**

Annual meeting. May 21. Att. 23.

Election of officers: G. R. Wright, chmn.; L. B. Stacey, vice-chmn.; D. M. Johnstone, secy. June 6. Att. 21.

**Washington**

Cleveland-Emerson Dial Project, by J. A. Remon, Chesapeake & Potomac Tel. Co. Dinner. April 12. Att. 160.

Functions and Operation of Meter Department, by W. H. Fellows, Potomac Elec. Pwr. Co. Election of officers: Prof. T. J. MacKavanagh, chmn.; Roland Whitehurst, vice-chmn.; E. T. Walker, secy.-treas. Dinner. May 10. Att. 75.

## Past Branch Meetings

**Armour Institute of Technology**

Election of officers: H. Rychlick, chmn.; R. Snelling, vice-chmn.; H. Schwennesen, secy.; E. Dumser, treas. June 10. Att. 41.

**Carnegie Institute of Technology**

Electrical Achievements of 1931, by W. B. Spellmire, Genl. Elec. Co.; Experiences in the General Electric Student Test Course, by H. S. Young, Jr., Genl. Elec. Co. May 27. Att. 39.

**Michigan College of Mining and Technology**

Election of officers: Jerome Williams, chmn.; Leon Messenger, vice-chmn.; Fredrick Plaga, secy.; Robert Simpkins, treas. June 1. Att. 12.

**Milwaukee School of Engineering**

Progress of Aviation in the United States, by C. E. Mayhue, Kohler Aviation Corp. Election of officers: Gale Young, chmn.; Wm. Kettenacker, vice-chmn.; Roy Christianson, secy.; Anthony Flout, treas. June 8. Att. 102.

**University of Minnesota**

Election of officers: Paul Erickson, chmn.; Arvid Turnquist, secy.-treas. May 24. Att. 36.

**University of New Hampshire**

Election of officers: Roger Hunt, chmn.; Leslie Huse, vice-chmn.; Philip Thomas, secy. April 23. Att. 24.

Thyratron Tubes, by L. A. Barker, student; Characteristics of a Motor With a Centrifugal Pump Directly Connected to the Motor, by P. A. Rolfe, student; An Experiment on Concatenation, by V. T. Swain, student. May 14. Att. 21.

Transformer Harmonics, by H. J. Joyal, student; Electrical Transients, by H. Wood, student; Magnetic Brakes, by B. Booth, student. May 21. Att. 19.

**College of the City of New York**

Election of officers: John Ragazzini, chmn.; Charles Grossfeld, vice-chmn.; Richard Brill, secy.; G. B. Criss, treas. May 19. Att. 21.

**University of North Dakota**

Business meeting. May 25.

**Pratt Institute**

Shot-Gun Fuses, by A. F. Bruder, student. May 26. Att. 20.

Election of officers: Galen Allison, chmn.; Raymond Farrell, vice-chmn.; Allan Tiffany, secy.; George Stringer, treas. May 27. Att. 30.

**Stanford University**

The Five Year Plan in Relation to Engineering, by P. M. Narbutovskih, student. Election of officers: George W. Dunlap, chmn.; G. E. J. Jamart, vice-chmn.; L. J. Lewis, secy.-treas. June 1.

**Texas Technological College**

Population Forecast, by Arthur Waghorn presented by J. P. Conner, students. Film—"Speeding Up Our Deep Sea Cables." Election of officers: J. P. Conner, pres.; Walter Cox, vice-pres.; S. A. Cousins, secy.-treas. May 18. Att. 17.

**University of Washington**

Milwaukee Electrification, by R. Beeuwkes, Chicago, Milwaukee, and St. Paul Ry. Co. May 26. Att. 44.

**University of Wisconsin**

Calculation of Magnetic Flux Density and Force Between Bus Bars, by W. E. Wyss, student. March 8. Att. 23.

Prospecting in Science, by M. W. Hanks, Hankscraft Co. April 20. Att. 65.

The Use of Models at Short Wave Lengths in Antenna Investigations, by G. H. Brown and R. King, students. Election of officers: W. E. Wyss, chmn.; H. H. Kieckhefer, vice-chmn.; L. A. Leifer, secy.-treas. May 18. Att. 26.

# Employment Notes

## Of the Engineering Societies Employment Service

## Positions Open

EXEC. DESIGNING ENGR. for oil switch division. Must be fully trained E.E. thoroughly experienced in the modern design and construction of high tension overhead equipment, especially oil switches. Must have executive ability and speak German fluently. Apply by letter stating complete information as to age, education, experience, references, salary, etc. Location, Europe. W-3754-CS.

## Men Available

### Construction

ASSOC. A.I.E.E., B.S. IN E.E., 33, single, 10 yr. experience in construction with contractor, 1½ yr. instructor in high school, 2 yr. field engr. during a survey with utility. C-8633.

GRAD. E.E., 29, 5 yr. supervisory construction, design, estimating and field engg. experience on super-power plants and substations; 4 yr. industrial pwr. plant operation, elec. construction and maintenance experience; ry. electrification construction experience. C-4428.

PRACTICAL ELEC. CONSTRUCTION CHIEF, 32, single, 14 yr. experience in construction and also maintenance work. Last 4 yr. in Latin-America. Can speak Spanish and German fairly well. Available immediately. Location, immaterial. C-2101.

### Design and Development

GRAD. E.E., M.I.T., 1923, 31, single. Design of steam and hydro gen. stations. Substations, pwr. transmission lines and industrial installations. Available immediately. Location, immaterial. D-1008.

E.E. GRAD., 29, single, 2 yr. additional study in accounting, 2 yr. experience on elec. wiring of bldgs., 5 yrs. experience on elec. and mech. design, development, and lab. work on fans and small motors with leading mfr. Also experience in drafting and commercial engg. New England preferred. D-580.

E.E. GRAD., 29, single, 5 yr. experience including 6 months testing a-c., d-c. machines, 4½ yrs. design 5 to 2,000 hp. a-c. and d-c. motors for industrial and special applications. Thoroughly familiar with motor quotations, estimates and applications. Desires position with utility, mfg. or construction firm. Location, U.S. Available immediately. D-944.

ELEC.-MECH. ENGR., 30, married, college grad. with unusual abilities for elec. relay circuits (autom. teleph., control, alarm systems, signaling), resourceful mech. designer on small apparatus, 5 yr. engg. experience. Available immediately. Location, immaterial. C-8373.

EMPLOYERS—Should you require a designer or operator for elec. transmission and distribution or a pwr. salesman, permit me to qualify. B.S. in E.E. and 7 yr. diversified utility experience. B-9709.

### Executives

B.S. AND E.E., 20 yr. experience; test, instructor 2 yr., line supt., constr. engr. large mining co., elec. engr. lighting and pwr. co.; engr. for utility holding co. Experience covers constr., design stations, substations trans., dist. lines, P.F. correction, line calculations, economic studies, system planning. Will go anywhere and accept any salary. D-1064.

GRAD. E.E., 1927, single, 26. Experience: 18 months cable development, 2 yr. installation and service engr. on talking picture theater equip. including foreign service. Additional education 1 yr. genl. course economics, etc., Univ. of London. Position desired offering experience with economic problems or personnel relationships. D-1159.

EXEC. ENGR., Scandinavian, 43, Amer., with 20 yr. experience in design and research of pwr. stations, transmission lines, transformers, and oil circuit breakers, desires position in U.S. or abroad for pwr. or mfg. co. Speaks German and Scandinavian fluently and is thoroughly familiar with Amer. and European Mfg. methods. D-1176.

EXEC. ENGR., mech. and elec., 43, Amer., col. grad. Broad experience in designing, bldg. and operating large industrial pwr. plants. Have exceptional qualifications for rapid, thorough and economical engg. of such projects and the ability to obtain maximum value for the entire investment. D-986.

E.E. GRAD., 12 yr. experience in distribution circuit work, design, testing, etc., and having a completed training in law, desires a position for which experience will qualify. D-1177.

DISTRIBUTION ENGR., tech. grad., 30, married, 8 yr. experience in design, construction and operation of rural and urban distribution systems and evaluation of systems. Best of references. Available at once. C-4247.

ELEC. AND MECH. ENGR., 36, exec., 12 yr. experience in design, construction, development, investigations of pwr. projects and systems expansion for utilities and industrials in the states and abroad. Speaks Spanish and Portugese. D-857.

EXEC. ASST. to pres. or vice-pres. of holding or large operating utility. Twenty yr. experience in construction, engg. and operation, transmission, distribution, city and rural substations, pwr. stations, appraisals, rates, right-of-way, interconnections and reports. East preferred, not essential. D-1246.

### Instruction

E.E. GRAD., 1929. G.E. test experience including work in radio and vacuum tube engg. dept.; and with all types of elec. machy. Received M.S. June 1932. Desires teaching or engg. opportunity. D-1036.

E.E. GRAD., 25, married, 4 yr. exceptional tech. experience, some very successful teaching experience. Desires position as instructor in E.E. subjects, mathematics or physics with opportunity of taking graduate work. C-4303.

E.E., Bachelors and Professional degrees, have held responsible teaching position in state institution and have had research experience. Location is not a material consideration. B-7263.

MEMBER, B.SC. IN E.E. Experience: lecturer; asst. prof. and prof. in charge of E.E. dept. of prominent univ., followed by practical design, latterly in charge of a-c. design for well-known mfr. of elec. machy. Desires position teaching or one which demands thorough knowledge of motors. D-1213.

### Junior Engineers

E.E. GRAD., 1932, Mich. State Col., 23, singl. Desires engg. work, but will consider anything. Experience in drafting and telephone work. Available at once. Location in Middle West preferred, others considered. D-1236.

E.E. GRAD., 1931, single, 24. Special training in radio, sound apparatus, and photoelectric cells. Desires position in the radio or electroacoustical field or teaching opportunity. Location, immaterial. Available immediately. D-1240.

E.E. GRAD., B.S. IN E.E., Univ. of Ill., 1932, 23, single. Ten months long distance telephone test A. T. & T.; 2 months motion picture sound equipment. Familiar with vacuum tubes and their applications. Available at once. Location, immaterial. D-1108.

JUNIOR ENGR., 1932 grad. of a cooperative tech. col. Has had experience with illumination design; radio manufacture and service. Location, immaterial. D-1109.

GRAD. IN E.E., 1932, 21, desires position immediately, strong physique. Will take anything. Location, immaterial. D-1010.

B.S. in E.E., 1932; single. Fourteen months G.E. test between junior and senior yr. Test records available. Excellent scholastic record. Tech. type: developed thesis; 9 contributions presented at A.I.E.E. Good personality and initiative. Location and salary immaterial. D-1127.

1931 GRAD., Cornell Univ. and Pratt Inst. in Brooklyn. Slight experience with vacuum tubes and resistors. Desires work in radio television, communication, or lines allied to that industry. Available on short notice. Location, immaterial. C-5636.

EXPERIENCED 1932 GRAD., 24, single. Vacuum tubes, photoelectric cells, circuits, research, design, and manufacture. Elec. measurements, especially with cathode ray oscillograph. Experienced in application of elec. methods to mech. engg. problems. Full or part time work. Location preferred, vicinity of New York City. Available after Aug. 15. D-616.

B.S. IN E.E., Carnegie Inst. of Tech., 1932, 5 yr. in radio work and repairing household appliances. Salary immaterial at start. Location, immaterial. Available at once. D-1140.

E.E., 22, single, good references; desires work in generation or transmission of elec. pwr. Satisfied with small salary in order to gain knowledge in field. Has had 2 yr. experience as cooperative student in manufacture of motors and generators. Can locate anywhere. D-159.

E.E. GRAD., 1932, 22, married. Experience in solution of distribution network problems. Desires position in any field of engg. with opportunity for advancement. Salary and location, secondary. Good scholastic record. D-1160.

GRAD. E.E., Rensselaer Poly. Inst., 1932, 23, single. One summer's work on relay squad of N. J. Pub. Serv. Desires position in any E.E. field, preferably illuminating. Available at once. D-1158.

E.E. GRAD., 1930, Columbia, 6 yr. course, 25, single, 1½ yr. with Paramount Publix Theatre Construction. Knowledge sound and projection equip., drafting, supervision of construction and layout; instruments, foundry, and pattern shop methods. Desires connection, any engg. capacity. Available immediately. Present location, New York but willing to go anywhere. C-7239.

1932 GRAD., E.E., B.S., from Ohio Northern Univ., 23, single and excellent physical condition. Best of character standing and willing to work hard, starting at the bottom and working up. Desires any position that will pay a living wage. Location immaterial and available immediately. D-1167.

E.E. GRAD., 1931, 25 single, cooperative col.; 12 months experience as asst. in production lab. of a battery mfg. concern. Six months experience as a genl. draftsman. Speaking and reading knowledge of German. Desires position with future.

## ENGINEERING SOCIETIES EMPLOYMENT SERVICE

57 Post St.
San Francisco

205 West Wacker Drive
Chicago

31 West 39th St.
New York

MAINTAINED by the national societies of civil, mining, mechanical, and electrical engineers, in cooperation with the Western Society of Engineers, Chicago, and the Engineers' Club of San Francisco. An inquiry addressed to any of the three offices will bring full information concerning the services of this bureau.

**Men Available.**—Brief announcements will be published without charge; repeated only upon specific request and after one month's interval. Names and records remain on file for three months; renewable upon request. Send announcements direct to Employment Service, 31 West 39th Street, New York, N. Y., to arrive not later than the fifteenth of the month.

**Opportunities.**—A weekly bulletin of engineering positions open is available to members of the cooperating societies at a subscription of $3 per quarter or $10 per annum, payable in advance.

**Voluntary Contributions.**—Members benefiting through this service are invited to assist in its furtherance by personal contributions made within 30 days after placement on the basis of 1.5 per cent of the first year's salary.

**Answers to Announcements.**—Address the key number indicated in each case and mail to the New York office, with an extra two-cent stamp enclosed for forwarding.

Location and salary secondary. Available immediately. D-534.

GRAD. E.E., 26, single. Two yr. experience in maintenance, test, and distribution with utility. One yr. drafting and mech. design. Two yr. elec. control sales. Available on short notice. Eastern location preferred. C-6445.

E.E. GRAD., Master's deg., V.P.I., '30, 23, married. One summer in relay dept. pwr. co., 1 yr. teach. fellow, 1 yr. teach. elec. in H.S. Six summers certified electrician. Needs engg. position in utility or industrial concern, or instructor in physics, mathematics or E.E. D-1198.

E.E. GRAD., Yale, B.S., Cum Laude, 1931. M.S. in E.E., 1932, 22, single. Desires experience with utility or industrial concern. Available immediately. Location anywhere in U.S. Northeast preferred. D-1212.

RECENT GRAD., B.S. IN E.E., 23, Newark Col. of Engg., cooperative training with Diehl Mfg. Co. Desires opportunity with future in production or sales. Previous experience in organization. Prefers location in New York metropolitan area. Available at once. D-1137.

E.E. GRAD., cooperative course, Drexel Inst., B.S., 1931. M.S., M.I.T., 1932, 23, single. Two yr. experience in plant dept. of Bell Tel. Co. of Pa. Desires engg. or teaching position. Location in East preferred. Available immediately. References upon request. D-1087.

B.E.E., Northeastern Univ., 1932. Experienced in utilities meter and station repair dept. Good references. Available at once. Location, immaterial. D-1211.

E.E. GRAD., 1932, 24, single. B.S. in E.E. from well known engg. school. Good scholastic record. Four yr. mfg. experience includes timekeeping, cost work, maintenance and assembly. Desires position with opportunity for advancement with utility, engg., or mfg. firm. Location preferred, Ohio-Pa. vicinity, but will consider others. D-908.

E.E., married, E.E., M.E. Twenty-two yr. experience, designing, construction pwr. plants, substations, transmission, distribution systems, and industrial plants, three yr. charge purchasing engg. equip., foreign interests. Three yr. exec. experience, charge engg. dept. large utility syndicate. English, German, Russian, Armenian, Turkish languages. Available immediately. D-84.

1932 GRAD., Univ. of Ala., 21, single, desires position in any engg. field. Languages: English, German, and Polish. Available immediately. Location, immaterial. D-1166.

E.E., grad. 1928, 28, married. 3½ yr. Westinghouse test course. Good experience on motors and control apparatus; also some civil engg. and supervisory experience. Not afraid of responsibility. Desires a position with future. Location, immaterial. C-9568.

E.E. GRAD., 1932, cooperative col. One yr. with Weston Instrument Co. in various dept. 1 yr. genl. maintenance work. Desires position with any mfg. or engg. concern. Location, immaterial. D-1112.

B.S. in E.E. from Worcester Poly. Inst., 1932, 24, single. Desires engg. work of any nature. With construction company for 4 summers. Location, immaterial. Very good references can be furnished. D-1227.

CORNELL E.E. 1932, A.B. 1930, 23, single, communications option, experienced in design and operation of radio and public address equip. One summer in Bell Tel. Lab. Two summers elec. construction on substations and plant additions. Can write clear concise letters and reports. Salary secondary, East preferred. Available October 1. D-1221.

B.S. 1930, E.E. 1931 from Univ. of So. Car., 23, single. Six months experience with South Carolina Pwr. Rate Investigating Committee. Able and willing to do practically any type of engineering work. Available immediately. Location, immaterial. Can give best of recommendations. D-595.

ENG. GRAD., R.P.I., 1932, E.E. Desires position, preferably pwr. or communications. Location, immaterial. Some experience in drafting. Graduation thesis design of central station. D-1245.

**Maintenance & Operation**

E.E., B.S. in E.E., 1930, Univ. of Idaho, 24, married. Two yr. with Bell Tel. Lab. in trial installation of new circuits and equip., chiefly telephone equip. for broadcast networks and transatlantic communication. Desires work in an industry or utility with opportunity for advancement. Location, U.S.A. Available at once. D-1001.

E.E. GRAD., 1928, Tri-State Col., 27, single, 3½ yr. engg. experience with utility in design, layout, and detailing of pwr. plant, substations and distribution lines. Desires connection in engg. or operating capacity, in steam pwr. plant. Location, immaterial. Now available. D-89.

RADIO ENGR.-OPERATOR. Fifteen yr. commercial experience; last 8 in broadcast stations including 3 yr. with KDKA. Now with station in metropolitan area. Would like connection with small Southern station. Able to design and construct latest type radio equipment, also serve as operator (licensed). D-1237.

TRANSFORMER ENGR., experienced, installation, care, maintenance, design large pwr. transformers. Nineteen yr. with mfg. transformer where work included preparation of instructions for transformer, erection and examination of failures and determining probable cause. Would be valuable to concerns with number of transformers under their supervision in seeing transformers are properly used, attended, operation. Married. B-199.

RY. E. E., 43, specialist on heavy elec. traction installation, practical operation, and maintenance. E.E. grad., 8 yr. with G. E. Co. in testing, engg., and sales work. 12 yr. in installation, operation, and maintenance of electrification of the C.M.St.P.&P. RR. Contributor to tech. magazines on elec. traction subjects. References and other information furnished on request. Available at present. D-1263.

**Research**

E.E., 1930, with 2 yr. research work, post graduate study and excellent scholastic record, desires tech. work, preferably mathematical. Location, Northeastern U.S. preferred, but will consider others. D-1183.

E.E. GRAD., 23, Sc.M., M.I.T., Harvard 28; Sc.D., M.I.T., June '32; single, 38; 9 yr. practical experience pwr., business and communication engg.; 2 yr. testing course. Recently made valuable contribution to knowledge net work synthesis. Speaks Swedish, English, German. Reading knowledge French. Desires position, well-known organization preferably communication engg. Available July 15. D-747.

GRAD., Yale 1930, B.S. in E.E., Tau Beta Pi, Assoc., Sigma Xi. Test experience, regulators, motors, industrial control, rectifiers, transformers, photoelectric cells, short circuit lab., work's lab. on insulation, and development work, research lab. Desires employment leading to exec. position. New England preferred. D-1192.

GRAD. E.E., Univ. of Toronto, Canada, 1929. Practical transformer construction experience drafting; 6 mo. test course, Can. Westinghouse; 3 yr. with large U.S.A. alloy co. in supervisory capacity on elec. furnace process and plant operation. Location, immaterial. Available immediately. D-1226.

DEVELOPMENT ENGR., 26, single, E.E. and M.S., high scholastic rating, 3 yr. G.E., research, test and field engg., 2 yr. development of pwr. plant equip. for telephone offices. Location, immaterial. Best of references. Available now. D-1219.

B.S. in E.E. and M.A. in Physics, 25. Three yr. experience at leading industrial lab. in research on vacuum tubes and associated circuits. Desires development work on radio, communication or sound equip., research or teaching E.E. and physics. D-1233.

MECH. and E.E.: Development, research. Elec. motor control, hoisting and conveying, mech. and elec. tests of materials, metallurgy, metallography X-ray analysis. C-6994.

# Membership

## Applications for Election

Applications have been received at headquarters from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the acting national secretary before Aug. 31, 1932.

L. A. Cantin, E. E. Student, Angola, Ind.
Cater, F. L., (Member) W. R. Grace & Co., N. Y.
City.
Crooks, C. L., Pub. Serv. Dept., Glendale, Calif.
Frey, J. C., Hatzel & Buehler, Inc., N. Y. City.
Hartong, H. H., 100 Haven Ave., N. Y. City.
Hildebrandt, C. H., N. Y. Central R. R. Co.,
Weehawken, N. J.
Hobson, L. S., Genl. Elec. Co., Phila., Pa.
Kallenbach, G. K., N. Y. Pwr. & Lt. Corp., Pleasant
Valley, N. Y.
Kaul, R. D., Garrison Fire Detecting System Inc.,
N. Y. City.
Miller, R. D., (Member) The Pacific Tel. & Tel.
Co., Portland, Oregon.
Rose, M. C., C. & P. Telephone Co. of B. C.,
Baltimore, Md.
Schnyder A. P. (Member) c/o Geo. F. Hardy,
Construction Engr., N. Y. City.
Schleicher, M., 11 Cottage Place, White Plains,
N. Y.
Simm, S. G., c/o Clyde R. Place, Engr., 420 Lex-
ington Ave., N. Y. City.
Sullivan, A. H. (Member) Cincinnati Union
Terminal Co., Ohio.

Kearny, N. J.
Wiley, Walter S., 200 Fackney St., Carmi, Ill.

# Engineering Literature

## New Books
## in the Societies Library

Among the new books received at the Engineering Societies Library, New York, during June are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no responsibility for statements made in the following outlines, information for which is taken from the preface or text of the book in question.

INTERNATIONAL UNEMPLOYMENT, a Study of Fluctuations in Employment and Unemployment in Several Countries, 1910–1930. M. L. Fleddérus, ed. Hague, Holland, and New York, International Industrial Relations Institute, 1932. 496 p., 10x7 in., cloth, $2.50.—For the 1931 Social Economic Congress at The Hague various nation's economists were asked to prepare studies on employment fluctuations to picture the recurrence of unemployment during the last 2 decades. The studies presented in this volume factually show conditions in Australia, Canada, China, Germany, France, Great Britain, the United States, and Russia.

LOAD CURVES AND POWER INDEXES IN THE OPERATION OF ELEC. STATIONS. (In Russian.) By A. K. Darmanchev. 1931, Moscow and Leningrad, Gosudarstvennoe Nauchno-Tekhnicheskoe Izdatelvstvo. 119 p., 9x6 in., paper, no price given.—According to Mr. Darmanchev, load curves usually are discussed solely in relation to power plant layout. In the present book they are considered from the point of station operation. The theory of load curves is set forth, and ways in which they may be applied described in detail.

METALLURGY. By E. Gregory. London and Glasgow, Blackie & Son, 1932. 284 p., illus., 9x6 in., cloth,, 17s 6d.—With an introduction by an experienced teacher. A simple, interesting account of the manufacture, properties, and uses of the common engg. metals. The metallurgy of ferrous materials fills 2/3 and includes chapters on the constitution of metallic systems, metallography, and heat treatment, alloy steels and stainless steels. Remainder treats of common non-ferrous alloys.

RAMBLING THROUGH SCIENCE. By A. L. De Leeuw. N. Y. & Lond., McGraw-Hill, Whittlesey House, 1932. 320 p., 9x6 in., cloth, $2.50.—Readers without special training in modern chemistry, physics, and astronomy will find satisfaction in these informal chapters. Mr. De Leeuw writes conversationally, simply, and clearly on light, sound, relativity, time, space, energy, matter, the elements, and other physical and chemical problems, giving an account which every one can understand of recent scientific discoveries.

REWINDING AND CONNECTING A-C. MOTORS. By D. H. Braymer and A. C. Roe. N. Y. & Lond., McGraw-Hill, 1932. 372 p., illus., 9x6 in., cloth, $3.50.—For technically trained men without shop or factory experience, and students. It aims to provide the fundamental principles of induction-motor windings, and shop information on lap and wave windings as used in current standard motors and in those in service for many years. This information based upon practical experience in rewinding is presented in form suitable for easy use.

ROYAL TECHNICAL COLLEGE JOURNAL, v. 2, Pt. 4, January 1932. Glasgow, Robert Anderson & Sons. p. 571–710, illus., 10x7 in., paper, 10s 6d.—Records research work recently carried out there. Of greatest interest to engineers are the physical properties of steel after plastic and yield-point extension, magnetostriction of cold-drawn wire, aging and tempering duralumin, segregation in steel, production of uniform illumination over large areas, the photoelectric cell, temperature stresses in non-circular drums and circular flat plates, and the performance of wing radiators.

THERMIONIC VACUUM TUBES and Their Applications. By E. V. Appleton. N. Y., E. P. Dutton & Co., 1931. 117 p., 7x4 in., cloth, $1.25.—A compact, accurate account of internal action of modern vacuum tubes and of their behavior when used as amplifiers, rectifiers, or generators of oscillations, written with the needs of students of general physics in mind.

DER INGENIEUR IN DER ELEKTROINDUSTRIE. By R. Salinger. Vienna, H. Martin, 1929. 118 p., 10x6 in., paper, 10 Aust. s.—This book is to assist the young electrical engineer to professional success. It contains much sage advice upon character formation and professional and commercial training, and discusses the qualities and training essential to various branches of the profession.

AMERICAN MACHINISTS' HANDBOOK. By F. H. Colvin and F. A. Stanley. 5 ed. N. Y. & Lond., McGraw-Hill, 1932. 1134 p., charts, tables, 7x4 in., leather, $4.00.—Popular for 24 years in machine shops and drafting rooms as a convienient source of reference on machine shop practise, standards, and materials. The new edition, the first in 6 years, has been revised carefully, obsolete material removed, and new data added.

APPAREILS POUR LE CALCUL MÉCANIQUE DE L'INTÉGRALE DU PRODUIT DE DEUX FONCTIONS. By A. Nessi and L. Nisolle. Paris, Dunod, 1932. 17 p., illus., 11x7 in., 7 frs.—Describes a mechanical integrator invented by the authors to give the integral of the product of 2 functions. The instrument is relatively inexpensive and can be dismantled into parts for other drafting-room purposes. The theory of the integrator is explained and illustrated.

ELECTRIC POWER EQUIPMENT. By J. G. Tarboux. 2 ed. N. Y. & Lond., McGraw-Hill, 1932. 493 p., illus., 9x6 in., cloth, $5.00.—To give the student already familiar with the fundamentals of electrical circuits and machinery a birdseye view of the entire field of electrical power equipment. Starting with a brief survey of power resources, prime movers, and the relation of steam to water power, it discusses loads and load graphs; then takes up generating and switching equipment circuit layouts, transmission lines, distribution systems, substations, and similar topics. The end is a short chapter on the economics of electric service. A new edition enlarged and thoroughly revised.

ELECTRICAL PHENOMENA IN GASES. By K. K. Darrow. Baltimore, Williams & Wilkins Co., 1932. 492 p., illus., 9x6 in., cloth, $8.00.—An important book which will be welcomed by physicists and chemists as a comprehensive up-to-date treatise, with general principles, methods, and experiments set forth clearly and fully. It fills admirably the need of systematic discussion of work in this field, and brings together data heretofore available only in scattered form.

ELEKTRISCHE MASCHINEN, BD. 3. DIE TRANSFORMATOREN. By R. Richter. Berlin, J. Springer, 1932. 321 p., illus., 10x6 in., cloth, 19.50 rm.—A text-book upon the theory and design of transformers, the subject presented concisely yet comprehensively, and emphasizing especially magnetic, electrical, and thermal phenomena. A clear, logical presentation suited to the needs of engineers and students. Includes brief bibliography.

ELEKTRODYNAMIK. (Handbuch der Experimentalphysik, by W. Wien and F. Harms, Bd. 11, Teil 1.) By G. Mie. Leipzig, Akademische Verlagsgesellschaft, 1932. 502 p., illus., 10x7 in., cloth, 45 rm.—A systemtic comprehensive presentation of the methods and apparatus used in the experimental study of electrodynamic phenomena. The magnetic field and the electric current, the dynamic effects of magnetic fields, and electrodynamic fields are discussed.

FIRST PRINCIPLES OF TELEVISION. By A. Dinsdale. N. Y., John Wiley & Sons, 1932. 241 p., illus., 9x6 in., cloth, $3.50.—Not an attempt to describe every system of television that has been tried, but rather to present the principles that have led to present results and to describe the apparatus now in use. After briefly presenting the most outstanding proposals of early workers, attention is confined to the workers who have gone farthest—Jenkins, Baird and the Bell Telephone Laboratories. These systems are described in considerable detail. In conclusion, the present state of television in Germany, England, and America is discussed.

FIXED NITROGEN. (American Chemical Society, Monograph Series No. 59.) Ed. by H. A. Curtis. N. Y., Chem. Cat. Co., 1932. 517 p., illus., 9x6 in., cloth, $12.00.—The product of a dozen authors, all past or present members of the Fixed Nitrogen Research Laboratory staff at Washington. The main theme is exposition of scientific facts and theories of nitrogen fixation, and of the essentials of commercial processes to obtain and elaborate nitrogen compounds. An extensive bibliography is given.

GENERAL TEXT ON AERONAUTICS. By H. F. Lusk. N. Y., Ronald Press Co., 1932. 420 p., illus., 8x5 in., cloth, $3.25.—Presenting fundamentals of aeronautics in form suitable for use in technical institutes, junior colleges, and aviation ground schools where students are in training for positions in the aviation industry. The principles of flight, construction of airplanes and engines, instruments used, piloting, meteorology, etc., are discussed in elementary fashion. A good introductory course covering information which the Department of Commerce expects airplane pilots to learn in ground schools.

HISTORY OF EXPERIMENTAL PHYSICS. By C. T. Chase. N. Y., D. Van Nostrand Co., 1932. 195 p., illus., 9x6 in., cloth, $2.25.—The book is devoted to the development of physics as an experimental science from the days of Galileo. Attention is directed to history making, researches, and reasons given as to why these are of interest. Present developments are clearly described non-mathematically. The book supplies an interesting account of the gradual advance in this field.

INTERNATIONAL TRADERS' HANDBOOK, incorporating foreign and domestic weights, measures, and moneys. Phila., Commercial Museum, 1932. 175 p., illus., 9x6 in., paper, $1.50.—Useful as desk book for manufacturers engaged in trade with foreign countries, presenting in brief convenient tables, the essential facts concerning trade centers and ports, language, transportation facilities, regulations governing freight and parcel post shipments, weights and measures, and conversion of moneys.

ORTSKURVEN DER STARKSTROMTECHNIK. By G. Hauffe. Berlin, J. Springer, 1932. 174 p., 10x6 in., cloth, 15.50 rm.—Here the method of complex quantities is systematically applied to the theory of locus curves, the book opening with a brief description of the method, followed by a concise summary of the necessary basic laws of electrical engineering. The application of the theory is illustrated by problems connected with oscillating circuits, air-core transformers, three-phase induction motors, and a-c. commutator motors. It closes with a systematic presentation of the general laws of the theory.

OUTLOOK FOR TELEVISION. By O. E. Dunlap. N. Y. & Lond., Harper & Brothers, 1932. 297 p., illus., 10x6 in., cloth, $4.00.—A book "to reveal the romance of television and its commercial possibilities; to record historically the evolution of a new era in radio science; and to explain its magic." The development of all important advances is traced chronologically and the various electrical systems, devices, and ideas used in the search for television are noted. Intended for the general reader, with the subject treated in a popular, non-technical style.

POTENTIALFELDER DER ELEKTROTECHNIK. By F. Ollendorff. Berlin, J. Springer, 1932. 395 p., 10x6 in., cloth, 32 rm.—A systematic course on the subject, intended to facilitate the solution of practical problems in electrical engineering. The opening chapters briefly summarize physical principles, after which the construction of potential fields is discussed at length. The latter half of the book considers boundary problems. Represents the course given at the Berlin Technical High School.

QUANTITATIVE ANALYSIS. By E. G. Mahin. 4 ed. N. Y. & Lond., McGraw-Hill, 1932. 623 p., illus., 8x6 in., cloth, $4.00.—A popular textbook to provide a theoretical and practical discussion to meet the needs of college students. Emphasis is placed upon the scientific principles that form the basis of practical methods of analysis. The book discusses the general processes, the special measurements used in laboratories, and the analysis of the common industrial products and raw materials. This edition has been revised throughout.

### Engineering Societies Library

29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a cooperative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

# Industrial Notes

**The Okonite Company Promotes Officers.**—According to a recent announcement, H. Durant Cheever, former president of the Okonite Company, has been made chairman of the Board, while the position of president is now occupied by Frank Cazenove Jones. Mr. Jones was formerly vice-president and general manager of the company, while in the new position he holds the title of president and general manager. Both men have long been members of the Okonite organization, Mr. Cheever's connection dating back for 44 years. Mr. Jones, who is also chairman of the Power Cable Group of NEMA, joined the Okonite Company after the war. His father, F. C. Jones, was manager of the Okonite factories.

**Hubbard & Co. to Manufacture Ohio Brass Line Hardware.**—The Ohio Brass Company, Mansfield, Ohio, announces that it has disposed of its line of wood cross-arm hardware, wood guy-strain insulators and steel insulator pins to Hubbard and Company, Pittsburgh, Pa. The latter company is licensed to manufacture and sell pole line hardware developed by Ohio Brass and protected by its patents. This is a manufacturing and sales arrangement only, and there is no financial interest of either company in the other. These materials, in the future, will be manufactured only by Hubbard and Company, although both companies will cooperate in the sale of the devices. Future development work on this class of materials also will be carried forward by both companies. Due to the specialized manufacture and engineering of similar materials by Hubbard, both companies expect that users will benefit by this cooperative arrangement.

**Large Clock Contract to Warren Telechron Company.**—Contracts for 2,650 synchronous electric clocks for three new government buildings were awarded the latter part of July to the Warren Telechron Company, Ashland, Mass. Approximately 1,100 clocks will be installed in the Department of Justice building, 1,100 in the Interstate Commerce Commission and Labor Department building, and 450 in the Post Office Department building. The recent installation of 875 Telechron clocks in the Internal Revenue building is one of the largest clock systems in the world.

**Special Electrical Machine for College Laboratories.**—It is sometimes difficult for students of electrical engineering to understand the relationship between direct and alternating-current rotating machines. If these relationships may be studied in a single machine, the connections being changed for the different conditions, it is easier for the student to visualize the actual operation. The Electric Specialty Co., of Stamford, Conn., therefore, has developed a machine which enables the student of electrical engineering to study the operation of the direct-current motor with and without commutating poles, the direct-current generator also with and without commutating poles, rotary converters operating from direct current to alternating current, or from alternating current to direct current, a-c. generators, and a-c. synchronous motors. The single machine may be used to illustrate the operation of all these types. Such a machine may also be equipped with exploring brushes for measuring the voltage between adjacent commutator bars in any position while in operation. A single conductor is also installed through one of the armature slots with each end terminating on a slip-ring fitted with brushes. This development has been completed for machines normally rated from about 3500 to 7500 volt-amperes as rotary converters. Machines of this size are about as small as could be used in order to obtain satisfactory results on all the different types of machines, and also are not so large as to involve too much expense in operation.

**New Time Switch.**—R. W. Cramer & Co., Inc., 67 Irving Pl., New York, announces a new type of Sauter synchronous motor time switch, gear operated. The new switch contains a self-starting, 200 r.p.m. sub-synchronous motor constructed to assure accurate time keeping on systems where controlled frequency is used. It can be had with either astronomic dial to automatically operate the switch in step with local sunset and sunrise throughout the year, or a plain dial to control either one or two complete operations in twenty-four hours. This switch is recommended by the manufacturer for use on alternating current circuits with regulated frequency.

# Trade Literature

**Overhead A-C. Network System.**—Bulletin C 1944, 8 pp. Describes the new application of economical secondary low voltage networks to low density load areas fed by overhead lines. Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

**Induction Motors.**—Bulletin 112, 4 pp. Describes Reliance fully enclosed, fan cooled induction motors, type AA, form F. Reliance Electric & Engg. Co., Ivanhoe Rd., Cleveland, O.

**Stainless Steel Motor.**—Bulletin, 4 pp. Describes "Linc-Weld" type "E" induction motor, totally enclosed, fan cooled, for use in dust or fume-laden atmospheres. The Lincoln Electric Company, Cleveland, O.

**Temperature Measurements in Electrical Apparatus.**—Bulletin 871, 28 pp. Describes the method and instruments employed in measuring temperatures in generators, transformers, and cable systems. Leeds & Northrup Co., 4901 Stenton Ave., Philadelphia, Pa.

**Squirrel Cage Motors.**—Bulletin 174, Part 5, 6 pp. Describes Wagner multi-speed squirrel-cage motors. Installation photographs are included as well as outlines of the problems involved in connection with each application. The description covers constant-torque, constant-horse-power and variable-torque motors, further classified as two-speed, three-speed, and four-speed motors. Wagner Electric Corp., 6400 Plymouth Ave., St. Louis, Mo.

**Electrical Tape.**—Pocket Bulletin, 16 pp. Describes a combination rubber tape and friction tape. The tape is made of fabric, completely imbedded in a unique rubber compound, and with a degree of adhesion and insulating value claimed to be far higher than ordinary tapes of this character. B. F. Goodrich Company, Akron, O.

**Copper Wire and Coils.**—Data sheets bound in loose leaf cover and convenient for ready reference. These bulletins are said to be the most complete and authoritative published up to this time on the subject. Inca Mfg. Div., Phelps-Dodge Copper Products Corp., Ft. Wayne, Ind.

**Cedar Poles.**—Pocket Bulletin, 100 pp., "Handbook of Cedar Pole Specifications." All available data on cedar poles is brought up-to-date in this new publication, featuring the new American Standards Association specifications for both western red and northern white cedar poles, and the new Western Red Cedar Association treating specifications. To facilitate handy reference to the old pole specifications, these are also included. MacGillis & Gibbs Co., 324 East Wisconsin Ave., Milwaukee, Wis.

**Oil Filled Cables.**—Bulletin. The Okonite-Callender Cable Company, Inc., a subsidiary of the Okonite Company outlines its new activity in manufacturing oil-filled, paper insulated cables. The company's factory at Paterson, N. J., is devoted to the production of impregnated paper-insulated cables of all types. In addition to its regular business of manufacturing the "solid" type of paper-insulated cables, its laboratory and plant have also been fully equipped for making cables of the oil-filled type. The pamphlet points out research and operating developments in extra-high voltage power transmission which have led to the application of oil-filled cables for certain conditions of use. In many underground plants, the growing needs for high operating voltages or for large conductors, without increasing the overall sizes of cables, have become important problems. As some power companies already have costly conduit systems which could not be enlarged or replaced without excessive cost, the application of the oil-filled cables may often present a feasible means of taking care of such conditions. The relative operating characteristics of the solid and oil-filled types are discussed in the bulletin and the subject matter should be interesting where such problems are existing, or where reviews of plant conditions indicate the need of revamping in the future.

CORRECTION. Through an error in the author's original manuscript, eq. 11 on p. 486 of the July issue of ELECTRICAL ENGINEERING is stated incorrectly; the correct form is $S = \frac{1}{2}\pi^2 E_0 \cdot \frac{c}{L} \cdot \frac{A}{L}$

MEMBERS of the Institute continue to express themselves upon various subjects through the medium of letters to the Editor. A selection from those received recently may be found in this issue. *p. 667–670*

OFFICERS AND COMMITTEES chosen to serve the Institute for the year 1932–33 were announced recently. *p. 678–681*

DESIGNED to provide primarily for the comfort and convenience of its occupants, the 33-story office building of the Philadelphia (Pa.) Saving Fund Society is said to contain the most modern electrical and mechanical equipment. The total connected electric light and power load is nearly 5,000 kw. *p. 621–624*

PRESIDENT HOOVER recently appointed 6 prominent engineers to serve as the engineering advisory board to the Reconstruction Finance Corporation. *p. 665–666*

EXPERIMENTS on the electric arc using pure iron electrodes in an inert atmosphere reveal information that may require a modification in the basic conception of the electric arc discharge. *p. 624–627*

A REPORT on proposed American standard electrical definitions is now available in pamphlet form. The report represents 3 years of effort on the part of a sectional committee of the A.I.E.E. standards committee, and contains 208 pages. *p. 670*

IF EXPERIMENTS on a 1,000-hp. locomotive with commutatorless motors confirm the results of laboratory tests, electric railway practise may be revolutionized. Mercury arc rectifiers replace not only the motor commutators but much expensive control apparatus as well. *p. 650–654*

BUT few operating difficulties have been experienced in 3 years of operation on the electrified portion of the Cascade division of the Great Northern Railway, which includes the famous 7.79-mile Cascade tunnel. Operating statistics show great savings in both time and expense in favor of electrical operation versus steam. *p. 627–633*

COMMITTEES are hard at work to assure those who will attend the Baltimore meeting, October 10–13, 1932, a profitable and enjoyable visit. Inspection trips have been arranged to some of the city's many attractions and to nearby points. The program includes also several sports events and special features for the ladies. *p. 663–665.* Technical papers to be presented deal chiefly with communication and power cables, and a major hydroelectric development. *p. 659–662*

A GREAT DEAL of engineering time and effort is being devoted to reducing lightning disturbances on electric power systems. Results of some recent studies on the protection of distribution systems are covered in a group of 3 articles in this issue. Tests show that interconnecting the primary lightning arrester ground with the grounded secondary neutral provides greater protection than is obtained with present conventional arrester connections. *p. 633–647*

*A Report on*

# Telemetering, Supervisory Control, and Associated Communication Circuits

*Prepared by a joint subcommittee of the A.I.E.E.**

THIS REPORT summarizes information as to telemetering and supervisory control systems in use today or commercially available in the United States, and includes a detailed discussion of the communication circuits suitable for such purposes. The form of the report is designed to make it convenient for a prospective or existing user of telemetering or supervisory control equipment to obtain information concerning the specific equipment in which he may be interested.

The tabulations in the telemetering and supervisory control sections enable the prospective user having in mind a certain requirement, for example the telemetering of a-c watts, to determine immediately the systems available for the purpose. The characteristics of each of the systems suitable for the telemetering of a-c watts may then be examined in detail with the aid of the table and consideration narrowed to a few systems concerning which additional information may be desired from the manufacturer in order to determine upon the one best suited to the conditions involved. The types of communication circuits suitable for operation with each telemetering or supervisory control system are indicated in the tables.

The information in the report has been arranged in 3 main sections:

I. Telemetering—including a tabulation of the characteristics of each system.

II. Supervisory Control—including a tabulation similar to that for telemetering.

III. Communication circuits—information concerning their use for Telemetering and Supervisory Control Systems.

Much of the information in this report has been contributed by the manufacturers. Information as to communication circuits has been obtained from the communication companies and other available sources.

No attempt has been made to include data covering the field operation and maintenance of the various telemetering and supervisory control systems.

**On this and the following 7 pages is given essentially the full text of an hitherto unpublished report concerning the present status of development of proven devices as used in telemetering and supervisory control services. The text of the report as published herewith was prepared by D. W. Taylor, chairman of the A.I.E.E. automatic stations committee, and E. I. Green, member of the joint subcommittee, to cover the subjects embraced by the original report, but of necessity eliminating the extensive and detailed tabulations of that report. However, in parts I and II of the accompanying article is given a comprehensive digest of the corresponding parts of the original report including an insight into the content and construction of the tabulations which form the major portion of those parts of the original report. Part III of the original report, presenting for the first time in published form a comprehensive discussion of the communication circuits and facilities involved in telemetering and supervisory control, is given here in its entirety. That the report in question may be kept up to date and improved in value, the committees involved earnestly solicit an interchange of information with all parties operating telemetering and supervisory control equipment. —Editors.**

---

Essentially full text (excepting extensive tabulations) of a report jointly prepared by the committees listed below and presented at the A.I.E.E. annual summer convention at Cleveland, Ohio, June 20–24, 1932. *A few lithographed copies of the full report are available at Institute headquarters for distribution to members vitally interested.*

*Joint subcommittee—C. F. Craig, *chairman;* A. E. Anderson, P. A. Borden, E. D. Doyle, E. I. Green, R. J. Wensley, F. Zogbaum.

Committee on automatic stations—D. W. Taylor, *chairman;* F. F. Ambuhl, A. E. Anderson, L. D. Bale, C. F. Craig, John Fies, A. M. Garrett, Joseph Hellenthal, C. A. Mayo, I. E. Moultrop, M. E. Reagan, O. J. Rotty, Garland Stamper, L. J. Turley, F. Zogbaum.

Committee on instruments and measurements—E. J. Rutan, *chairman;* H. S. Baker, R. D. Bean, O. J. Bliss, P. A. Borden, H B. Brooks, A. L. Cook, E. D. Doyle, W. W. Eberhardt, Marion Eppley, W. N. Goodwin, Jr., I. F. Kinnard, O. A. Knopp, A. E. Knowlton, H. C. Koenig, W. B. Kouwenhoven, F. A. Laws, E. S. Lee, J. B. Lunsford, Paul MacGahan, R. T. Pierce, W. J. Shackelton, H. L. Thomson, H. M. Turner.

# I—Telemetering

HEREIN *telemetering* is considered to be the indicating, recording, or integrating of a quantity at a remote point by electrical translating means. Electrical or mechanical quantities normally are involved, although there are other miscellaneous applications for telemetering.

## TYPES AND CHARACTERISTICS OF SYSTEMS

The numerous systems and combinations of equipment used for telemetering may be classified broadly on the basis of the translating means employed. Such classification has been recommended to the Institute for adoption, and includes: (1) Current, (2) Frequency, (3) Impulse, (4) Position, and (5) Voltage.

This report endeavors to present a uniform analysis of existing systems. The characteristics have been detailed under items which past engineering experience indicates to be essential to bring out the design, installation, and performance features. In order to cover the entire field, it has seemed desirable to present the information in tabular form. The user ordinarily will be concerned only with a limited number of systems, and the arrangement of the information is such that he easily can fix upon the system or systems which appear best to meet his requirements.

The different telemetering systems which have been included in the table are as follows:

| | Name of System | Manufacturer |
|---|---|---|
| 1. | Midworth distant repeater | J. G. Biddle Co. |
| 2. | Long distance transmitting and recording system | The Bristol Co. |
| 3. | Remote type transmitting and recording system | Brown Instrument Co. |
| 4. | TM flow meter | Builders Iron Foundry |
| 5. | MacCreedy fluid level indicator | J. H. Bunnell & Co. |
| 6. | Long distance recorder | Esterline-Angus Co. |
| 7. | "Elinco" remote indicating system | Electric Indicator Corp. |
| 8. | Magnetic impulse telemeter | General Electric Co. |
| 9. | Rectified current telemeter | General Electric Co. |
| 10. | Torque balance telemeter | General Electric Co. |
| 11. | Selsyn equipment | General Electric Co. |
| 12. | Demand metering system | General Electric Co. |
| 13. | Distant dial system | General Electric Co. |
| 14. | Long distance outfit | W. & L. E. Gurley |
| 15. | Telemetric gage | James S. Kennedy |
| 16. | Micromax thermal converter telemeter | Leeds & Northrup Co. |
| 17. | Micromax potentiometer transmitter telemeter | Leeds & Northrup Co. |
| 18. | Micromax voltage multiplier telemeter | Leeds & Northrup Co. |
| 19. | Micromax current balance telemeter | Leeds & Northrup Co. |
| 20. | Micromax wheatstone bridge telemeter | Leeds & Northrup Co. |
| 21. | Stevens Type P recorders and indicators | Leupold, Volpel & Co. |
| 22. | Stevens Type G recorders and indicators | Leupold, Volpel & Co. |
| 23. | Telemco gage | Pittsburgh Equitable Meter Co. |
| 24. | Conductance meter | Republic Flow Meters Co. |
| 25. | Fluid meter register | Simplex Valve & Meter Co. |
| 26. | Tanner type telemeter | Wallace & Tiernan Products Co. |
| 27. | Wallace type telemeter | Wallace & Tiernan Products Co. |
| 28. | Electronic current balance system | Westinghouse Elec. & Mfg. Co. |
| 29. | Current balance system | Westinghouse Elec. & Mfg. Co. |
| 30. | Low rate impulse system | Westinghouse Elec. & Mfg. Co. |
| 31. | High rate impulse system | Westinghouse Elec. & Mfg. Co. |
| 32. | Rectox system | Westinghouse Elec. & Mfg. Co. |
| 33. | Position indicator | Westinghouse Elec. & Mfg. Co. |

The characteristics of the above systems are listed in the tables under the following classification.

**General**
1. Manufacturer
2. Trade name
3. Method of operation (translating means)

**Character of Indications Provided**
4. Quantities measured
   Electrical Quantities
   a. Amperes, a-c
   b. Amperes, d-c
   c. Ampere-hours, d-c
   d. Frequency
   e. Integrated demand
   f. Power factor
   g. Reactive voltamperes
   h. Reactive voltampere hours
   i. Totalized watts, a-c
   j. Totalized watthours, a-c
   k. Volts, a-c
   l. Volts, d-c
   m. Voltampere hours
   n. Voltage phase angle difference
   o. Watts, a-c
   p. Watthours, a-c
   Other Quantities
   a. Levels
   b. Positions
   c. Pressures
   d. Quantities of flow
   e. Rates of flow
   f. Temperatures
5. Continuous or step-by-step indication

**Performance**
6. Speed of response—seconds
   a. Transmitter—zero to full scale reading
   b. Lag from transmitter to receiver
   c. Total
7. Estimate of maximum probable error under normal operating conditions (per cent of full scale)
8. Power requirements
   a. Transmitter
   b. Receiver
9. Will correct indication be given after:
   a. Interruption in power supply
   b. Temporary disconnection of line circuit

**Characteristics Affecting Line Transmission**
10. Frequency—cycles per second
11. Maximum number of impulses per minute
12. Is neutral or polar relay employed
13. Maximum allowable loop resistance—ohms
14. Minimum allowable insulation resistance—megohms
15. Number of conductors
16. Possibility of using ground as conductor
17. Possibility of using conductors exposed to high potentials
18. Possibility of using superposed circuits as conductors:
    a. Simplexed
    b. Composited
    c. Carrier

**Interference and Protection Features**
19. Normal line current
20. Maximum line current on short circuit
21. Maximum open circuit voltage
    a. Between wires
    b. To ground
22. Is additional equipment required to limit noise on adjacent telephone circuits
23. Description of system

### Power Supply at High Voltage Stations

The use of station batteries for the supplying of power telemetering transmitters located in high voltage stations is generally inadvisable. Station batteries usually are connected to an extensive network of local control wires having a high electrical capacitance to ground, and subject to contact or leakage to ground. For reliability a separate battery or other insulated source should be used. This battery should be charged from a separate, ungrounded generator or rectifier; and if alternating current be used it should be supplied from a separate ungrounded transformer fed from the low voltage station bus which should be grounded.

## II—Supervisory Control

SUPERVISORY control provides, by electrical means and over a relatively small number of conductors, for the selective control and supervision of several remotely located units of equipment or apparatus. It is the purpose of this report to present to the prospective user information that will enable him to select the equipment which will provide the desired operating features and at the same time function satisfactorily in connection with available communication circuits.

### Applications

At present, supervisory control systems have their greatest field of application in power systems, where they are used for the automatic operation of apparatus in generating, switching, transformer, or conversion stations. These systems are employed also in water, gas, oil, and other industries for the operation of pumping stations, and the control of levels and pressures of gases, liquids, etc. Supervisory control is applicable in general to the remote control and supervision of any device that may be operated electrically. A partial list of such devices is included in Section 26 (Automatic Stations) of A.I.E.E. Standards.

In addition to the control features provided, indications of the position of different devices such as switch positions, governor settings, gate and valve openings, and of such conditions as bearing and winding temperatures, pressures, levels, synchronization, may be secured. Arrangements for the telemetering of various quantities may be incorporated in control systems.

### Performance Features

Features generally desirable in supervisory control equipment may be summarized as:

1. The highest degree of reliability and speed obtainable in the correct selection of units, with due regard for economy.
2. Safeguarding of a selected unit against incorrect operation and the correct operation of a unit as quickly after its selection as is consistent with safety.
3. A visual and/or audible indication at the control point of changes occurring in the position of any of the supervised units.
4. Automatic notification at the control point of the occurrence of major troubles such as open, shorted, or grounded conductors, and the loss of operating potential in a distant station, that may cause the supervisory control system to become inoperative.
5. Safeguarding against false operation in the event of failure of any portion of the supervisory control equipment to function.

### Capacity—Power Supply

Some of the supervisory control equipments have structural features which impose more or less definite physical limitations as to the number of units that may be supervised from one system. Other equipments may be used to supervise any number of units that may be installed. Some stations may be of such size and importance as to justify more than one supervisory control installation.

The comments under telemetering relating to power supply practises in high voltage stations apply with equal force to supervisory control. In addition, special care should be exercised where supervisory wiring is connected to units located in a high voltage structure.

In the full report the supervisory control systems have been tabulated in a manner somewhat similar to the arrangement for telemetering systems. The following systems have been included:

| | Name of System | Manufacturer |
|---|---|---|
| 1. | Selectrol system | General Control Corp. |
| 2. | Synchronous selector system | General Electric Co. |
| 3. | 2-Wire synchronous selector system | General Electric Co. |
| 4. | 2-Wire code selector system | General Electric Co. |
| 5. | Code synchronous selector system | General Electric Co. |
| 6. | Audible selector system | General Electric Co. |
| 7. | Audible indicating system | General Electric Co. |
| 8. | Synchronous visual system | Westinghouse Elec. & Mfg. Co. |
| 9. | Visicode radial system | Westinghouse Elec. & Mfg. Co. |
| 10. | Visicode series system | Westinghouse Elec. & Mfg. Co. |
| 11. | Visicode parallel system | Westinghouse Elec. & Mfg. Co. |
| 12. | Audicode system | Westinghouse Elec. & Mfg. Co. |
| 13. | Televox system | Westinghouse Elec. & Mfg. Co. |
| 14. | Polaricode system | Westinghouse Elec. & Mfg. Co. |
| 15. | Polaricode radial parallel system | Westinghouse Elec. & Mfg. Co. |

Characteristics of the supervisory control devices covered by the report are tabulated therein, the tables embracing the following items:

General
1. Manufacturer
2. Trade name
3. Method of selection
4. Method of checking selection
5. Method of operation
6. Method of indication

Characteristics of System
7. Number of units
    a. Maximum recommended for one system
    b. Normal physical limitation
8. Maximum number of stations recommended for parallel operation over one group of communication circuits. (See item 20)
9. Power requirements
    a. Dispatching station
    b. Distant station

10. Time required to select and check
    a. 10th unit
    b. 20th unit
11. Having selected unit, can it be operated repeatedly without again performing selecting operation
12. Is automatic indication given to dispatcher
    a. Line open
    b. Line short
    c. Line ground
13. Can telephone conversation be carried over same communication circuit, intermittent or continuous
14. Is selective telemetering possible over same communication circuits
15. Is remote manual synchronization possible over same communication circuits

**Characteristics Affecting Line Transmission**

16. Maximum number impulses per sec
17. Is neutral or polar relay used
18. Maximum allowable loop resistance
19. Minimum allowable insulation resistance
20. Number of conductors
21. Possibility of using ground as a conductor
22. Possibility of using Superposed circuit as conductor
    a. Simplex
    b. Composite
    c. Carrier
23. Can system operate through insulating transformers

**Interference and Protective Features**

24. Normal line current
25. Maximum line current on short circuit
26. Maximum line volts open circuit
    a. Between wires
    b. To ground
27. How is system protected from electrostatic and electromagnetic induction when exposed to high potential circuits
28. Is additional equipment required to limit noise in adjacent telephone circuits
29. Description of system

# III—Communication Circuits

TELEMETERING and supervisory control systems may be operated over different types of communication circuits. It is not practicable to set down rules which will definitely determine the type of circuit to be used in a given case. The choice will depend upon the characteristics of the equipment, the available types of circuits, the operating distance, cost factors, and other circumstances. The transmission and engineering considerations involved in the selection are discussed in the following paragraphs.

## LINE SIGNALS—TRANSLATING MEANS

The systems described involve the transmission of the following types of signals:

1. D-c signals representing voltage or current, which change in accordance with the quantity to be measured.
2. D-c impulse signals, ranging in frequency from one impulse per minute to 15 impulses per sec.
3. Power frequencies, usually 60 cycles.
4. Frequencies in the voice range and above.

Only a limited use of frequencies in the voice range or above is being made in telemetering and supervisory control systems. The following discussion therefore is concerned primarily with circuits for the transmission of low frequency and d-c signals. The problems involved in the transmission of such signals over line circuits are similar in many respects to those encountered in d-c telegraph transmission and the same engineering considerations frequently apply.

Telemetering systems ordinarily transmit in one direction only, whereas supervisory control systems commonly require successive transmissions in opposite directions.

## CIRCUIT CHARACTERISTICS

Circuits for use with telemetering or supervisory control systems may be leased or may be owned by the user of the equipment. Both cable and open wire facilities are employed for these services, cable being in more general use. The line characteristics that may affect the operating range of low frequency systems are principally the linear resistance, to a lesser extent the leakage conductance (or insulation resistance), and occasionally the linear capacity or inductance.

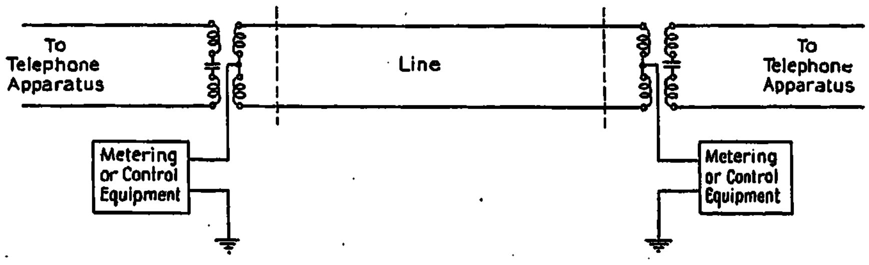

**Fig. 1. Grounded low frequency circuit derived from simplexed telephone circuit**

The gage of cable most commonly used is No. 19 A.W.G., although relatively short lengths of 22, 24, or 26 gage cable frequently are employed in cities.

The gages of open wire commonly employed by the communication companies are 165-mil (No. 8 B.W.G.), 128-mil (No. 10 N.B.S.G.), and 104-mil (No. 12 N.B.S.G.), which coincide closely with those frequently used by the electric utilities and other industries; namely, 162-mil (No. 6 A.W.G.), 128.5-mil (No. 8 A.W.G.), and 101.9-mil (No. 10 A.W.G.).

The insulation resistance of cable circuits ordinarily is so high that it is not an important factor in the operation of telemetering and supervisory control systems. The insulation values obtained on open wire circuits in general are very much lower than those for cable circuits. Consequently, leakage frequently is the limiting factor in determining the range over which telemetering and supervisory control systems may be operated on open wire facilities. The leakage conductance varies over wide limits, depending chiefly upon weather conditions and the type and maintenance of the line, and to a smaller extent upon the insulators employed. Since the leakage in dry weather is negligible compared to that in wet weather, it is common practise to engineer systems on the basis of wet weather leakage values. For the purpose of determining the approximate range and accuracy of telemetering and control systems, it appears convenient to employ a single leakage value which may be considered to be representative for any open wire circuit. On this basis, the

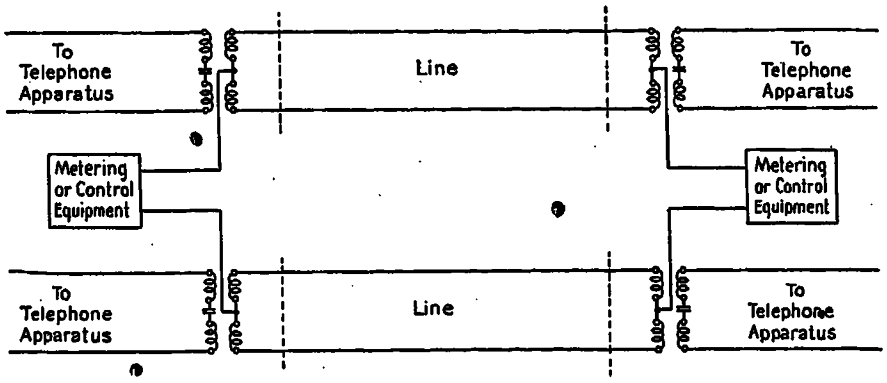

Fig. 2. Metallic low frequency circuit derived from simplexed telephone circuits

value of wet weather leakage conductance between one wire and ground may be taken as 5 micromhos per mile (0.20 megohm-mile). It is thought that on the average this value will not be exceeded on more than about one day out of a hundred and then only for a part of the day, although individual sections of the country may vary materially in this respect. The wet weather leakage conductance between wires probably will not be more than 2.5 micromhos per mile.

For determining the effect of uniformly distributed leakage conductance upon the accuracy of a d-c telemetering system, the percentage error usually may be taken as equal to 50 times the ratio of loop resistance in ohms to total insulation resistance in ohms.

The telemetering and control systems described require from 2 to 6 conductors, but since 2-conductor systems predominate, this discussion is directed primarily toward such circuits. The principles involved may be extended readily to systems requiring 3 or more conductors.

Circuits may be divided into 2 classes: metallic circuits in which a metallic conducting path is employed throughout, and grounded circuits in which the ground is used as one side. For many applications metallic circuits constitute a more desirable transmission medium than grounded circuits. However, the latter are satisfactory in many cases and ordinarily can be obtained at a low cost.

The simplest forms of circuits which may be used are: a circuit consisting of two conductors, and a circuit consisting of a single conductor and ground. More complicated arrangements are encountered when it is desired to superpose the telemetering or supervisory control channel on a circuit which also is used for telephone purposes. Such superposition is accomplished by simplexing or compositing.

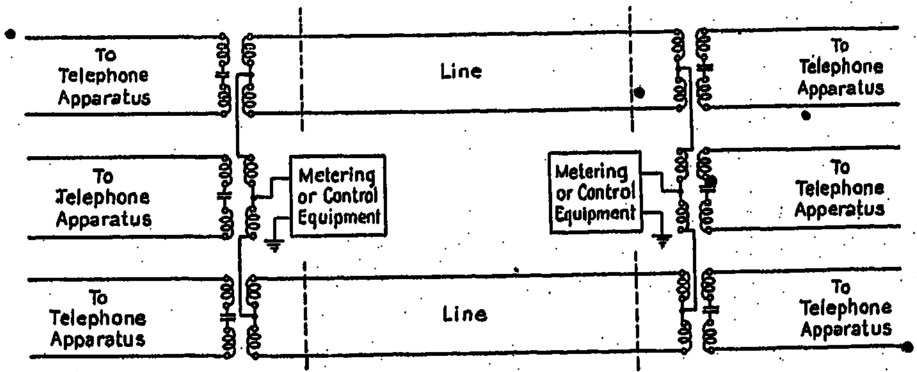

Fig. 3. Grounded low frequency circuit derived from simplexed phantom circuit

## SIMPLEX ARRANGEMENTS

The simplex method, illustrated in Fig. 1 as applied to the derivation of a grounded circuit, is based upon the principle of balance. If the telephone circuit is perfectly balanced there will be no net emf or current produced in either the telephone circuit or the derived simplex circuit by signals being transmitted over the other. The use of two telephone circuits to derive a single metallic low frequency circuit is shown in Fig. 2.

If a telephone pair is simplexed it cannot be used as a part of a phantom circuit. However, a phantom may be created from 2 pairs of conductors in the usual manner, and the phantom may be simplexed so as to give one grounded low frequency circuit over the four wires in parallel.

Simplexing connects the line conductors in parallel for the low frequency circuit. Circuit resistance thus is reduced correspondingly, but its linear leakage and capacity are increased.

## COMPOSITE ARRANGEMENTS

In superposing a low frequency circuit on a telephone circuit by compositing, use is made of frequency discrimination. The use of terminal composite equipment to derive 2 grounded low frequency circuits from a single telephone circuit is illustrated in Fig. 3 whereas Fig. 4 shows a single metallic low frequency circuit derived in a similar manner. The composite terminal equipment may be considered as consisting of a high-pass filter which freely transmits the telephone currents while attenuating the low frequency currents, and a low-pass filter which passes the low frequencies and attenuates the telephone frequencies. The low frequency band provided by the composite set extends roughly to 75 cycles, while the high frequency band extends upward from about 135 cycles.

## CONSIDERATIONS AFFECTING SUPERPOSITION

Transmission considerations involved in the use of simplexed or composited circuits for telemetering and supervisory control purposes are similar in general to those which apply in d-c telegraph transmission. For the longer open wire circuits it frequently will be desirable to composite rather than to simplex, because of the smaller leakage values obtained with composited circuits. Also, for the same reason

Fig. 4. Derivation of 2 grounded low frequency circuits from composited telephone circuit

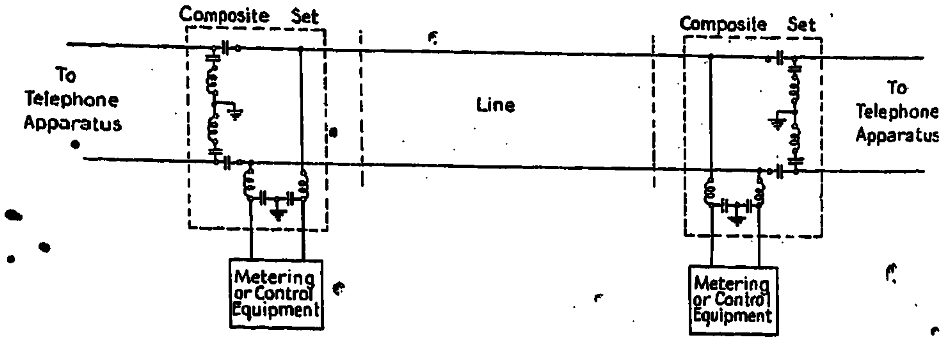

Fig. 5. Derivation of metallic low frequency circuit from composited telephone circuit

a composited open wire physical circuit normally is to be preferred to a composited open wire phantom.

Superposition frequently is accomplished not at the terminals of the telemetering or supervisory control system, but at some intermediate point, a simple metallic or grounded circuit being used from that point to the system terminal. The low frequency circuit may, of course, be superposed on several different telephone circuits in different parts of its length.

The circuit lengths for which superposition may be considered, ordinarily will be in excess of 1 or 2 miles.

### COMMON CIRCUITS

In some instances where a single metallic telephone circuit is available a suitable circuit arrangement will permit the use of this circuit also as a metallic low frequency circuit. In such cases the principal problem frequently is that of transmitting the telephone ringing current and the telemetering or control current without mutual interference. An arrangement employed for the derivation of a metallic circuit for a d-c telemetering system from a metallic telephone circuit is shown in Fig. 5. In this case the low frequency ringing (16 or 20 cycles) is applied to ground.

When several metallic circuits are desired between the same two terminals it is possible under certain conditions to use a single metallic conducting path as a common return, thus effecting an economy in the number of separate metallic paths required. This plan usually is feasible only for short distances where the circuit resistance is small in comparison with that of the terminals. It has been used successfully for systems employing d-c impulse signals.

### MAINTENANCE AND INTERFERENCE PROTECTION

Since telemetering and supervisory control services generally are of vital importance in the fields in which they are applied, the highest practicable degree of continuity and reliability of operation is essential in most cases. Some of the procedures which have been found helpful include:

1. Special markings at the terminals, frames, protectors, test boards, etc., where the circuits appear. These serve to guard against possible interference or interruption to service.
2. Frequent routine tests and inspections of the facilities.
3. Arrangements for prompt location and clearing of troubles.
4. Arrangements for prompt restoration of service in the event of failure.

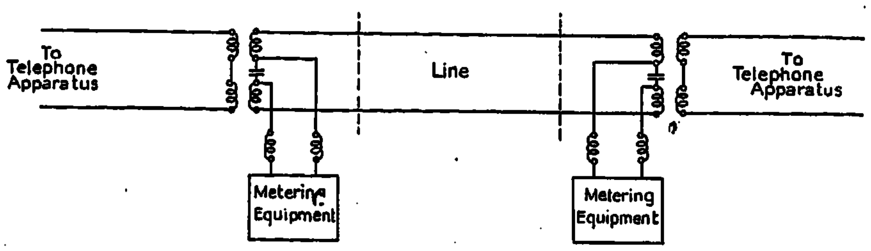

Fig. 6. Derivation of metallic d-c circuit from single telephone circuit

In operating telemetering and supervisory control systems in connection with different types of communication circuits, the application of certain requirements and limitations as to protection and interference conditions has been found desirable. These have been determined with a view to:

1. The provision of a satisfactory grade of telemetering and supervisory control service.
2. The avoidance of possible hazard to communication plant and personnel.
3. Avoidance of possible interference with communication services.

The requirements and limitations usually desirable for low frequency telemetering and supervisory control systems may be briefly summarized as:

a. The potential of a d-c supply under any conditions should not exceed 135 volts positive or negative between any conductor and ground. A potential of 270 volts may be employed between the 2 wires of a pair provided the midpoint of the applied voltage is grounded.

b. The potential of an a-c supply should not exceed 120 volts rms value between conductors or between any conductor and ground.

c. The maximum line current under any conditions should not exceed 0.35 amp. (In some types of loaded telephone conductors the maximum current is limited to 0.10 amp.)

d. Where there is a possibility of experiencing excessive ground potentials there should be no metallic connection between the line facilities and the high voltage station ground.

e. The apparatus should be provided with insulation adequate for the conditions under which it is to be used.

f. Not more than 50,000 noise units should be impressed on a paired metallic circuit. The noise impressed on any two wires not in the same pair, or between any wire and ground, should not exceed 10,000 noise units.

The communication companies generally are equipped to make noise measurements in cooperation with the user of the telemetering or supervisory control equipment. The above provisions agree, in general, with those observed in the operation of commercial telephone plant. When the user of telemetering or supervisory control equipment provides his own circuits it is sometimes possible to exceed these limitations without undesirable effects. Many of the systems now furnished by the various manufacturing companies are designed and constructed so as to conform to the provisions listed above.

### GROUND POTENTIALS AND THEIR EFFECTS

An item of interest in metering and control services is the possible occurrence of differences between the ground potentials at the two ends of the circuit that may be of sufficient magnitude to cause appreciable interference in grounded circuits. Metallic circuits, on the contrary, are very rarely affected by ground potentials.

Differences in ground potentials ordinarily are small (not more than 10 volts). However, in a few locations in the United States the geological formation is such that varying differences of substantial magnitude in ground potential occur more or less continuously. Difficulties incident to this cause may be overcome by an arrangement known as a ground potential compensator, which will neutralize ground potential differences up to about +100 volts.

The effect of ground potentials on telemetering and control circuits depends, of course, upon the type of system. As a rule, the accuracy of telemetering systems which use a slowly varying direct voltage or current is affected by ground potentials. Consequently, metallic circuits generally are more desirable for such services. Systems employing d-c impulses, however, are much less susceptible in this respect, and usually are not affected by small differences in ground potentials. Therefore, grounded circuits may be used successfully in many applications of these latter types of systems.

Where several telemetering or supervisory control systems employing relay operation are to be used between the same terminals, an arrangement may be provided whereby a grounded channel is used for each system and a single auxiliary conductor is used to compensate for the effect of ground potentials in all systems.

## Power Interference

In certain cases the transfer of energy from power circuits may introduce substantial alternating voltages and currents into circuits used for telemetering and supervisory control systems. If circuits closely parallel power line rights-of-way, special drainage and protection arrangements ordinarily will be required. In the more usual cases where signal circuits are less severely exposed to the power circuits, appreciable induction may be experienced during normal operation of the power system, but disturbances caused by abnormal occurrences on the power circuits, such as short circuits or grounds, will be of greater importance.

As in the case of differences in ground potential, metallic circuits are much less susceptible to power interference than are grounded circuits. Also, cable circuits are much less affected than open wire circuits. The amount of actual interference that such power induction may produce in telemetering and supervisory control systems depends, of course, upon the type of system employed and upon the magnitude of the effects present.

If a high voltage station ground or a nearby ground is used for grounded telemetering or supervisory control circuits these circuits are extremely susceptible to interference at times of abnormal conditions in the power system. This difficulty may be obviated by using an operating ground at an intermediate point (such as a telephone central office) some distance away from the high voltage station and employing a metallic circuit between that point and the high voltage station. This makes possible the use of a grounded circuit in sections not affected by disturbing potentials. The metallic circuit extending to the high voltage station must, of course, be insulated against the maximum potentials to which it may be subjected.

**Fig. 7. Common return circuits**

## Operating Distances

The distance over which satisfactory operation may be secured with different types of telemetering and supervisory control systems depends both upon the design of the system and the character of the associated communication circuits. Ordinarily the manufacturer will indicate the approximate length of different types of circuits over which his equipment will yield a satisfactory performance. The scope of this report does not permit a statement of the maximum distances which may be spanned with each equipment as applied to each type of circuit. A few general observations, however, may be helpful.

For cable circuits, especially of the metallic type, the resistance usually is the principal factor in determining the operating range. With open wire circuits, the leakage frequently will be the controlling factor.

For systems having the higher speeds of transmitting impulses and for 60-cycle systems, especially when operated on simplexed or composited facilities, the effects of capacity and inductance in the communication circuit and in the compositing equipment will limit the length to much shorter values than those determined by resistance only.

In general, the positions of type telemetering systems are best suited to comparatively short distances, perhaps up to 5 miles.

The voltage and current types of telemetering systems cover, in general, a range of operating distances up to about 50 miles, with greater ranges

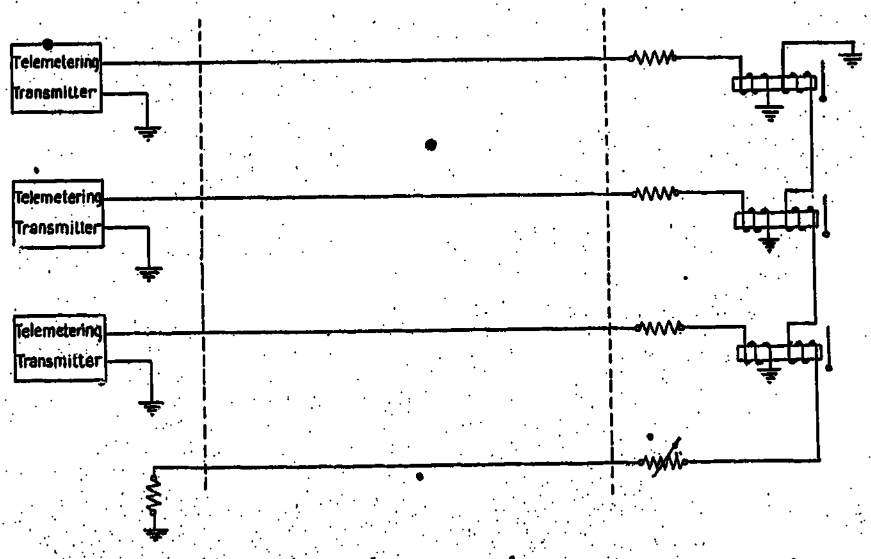

**Fig. 8. Use of auxiliary conductor to compensate for ground potentials**

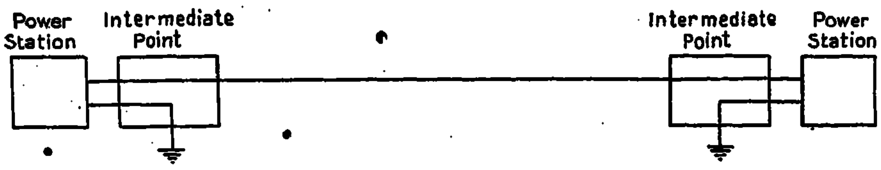

Fig. 9. Use of ground at intermediate points

feasible if simplexed cable circuits are used. The accuracy of these systems is affected appreciably by the leakage on open wire circuits. Metallic circuits are preferable for these systems; in fact, are essential for certain types.

Systems employing d-c impulses generally will span a maximum distance of from 50 to 250 miles or more. These systems are well adapted to the use of grounded channels, and their accuracy is not impaired by leakage conditions. For systems employing relay operation, greater distances usually may be spanned and superior operating results obtained by the use of polar operation or the equivalent instead of open-and-close operation.

Repeaters, for the most part, are unnecessary for the distances normally to be covered. In cases where it is desired to span unusually long distances, certain of the systems employing d-c impulse signals may be repeatered with ordinary telegraph repeaters. Also, repeaters employing equipment similar to the terminal equipment for some of the systems can be furnished by the manufacturers.

### Circuits for Voice Frequency

The employment of signals in and above the voice frequency range is practicable for telemetering and supervisory control systems, although in most cases d-c or low frequency signals have been used. Some of the more important reasons for their usage are:

1. The employment of the voice frequency range for these purposes sacrifices its utility for telephone purposes.
2. The avoidance of interference with adjacent services is readily obtained by the utilization of the low frequencies.

The protection provisions desirable for telemetering and supervisory control systems employing frequencies in or above the voice range are somewhat the same as for low frequency systems. Where there is a possibility of interference with other services, the amount of energy usually is determined on the basis that the signaling energy should be comparable in its interfering effect with the normal voice currents.

## IV—Conclusion

Considering the rapid advances in the art, a report of this nature, summarizing the present available information concerning telemetering and supervisory control systems, undoubtedly will be out of date in a relatively short time. It is hoped that frequent contributions will be received from users of telemetering and supervisory control equipment reporting their experiences with this apparatus so that this report may be supplemented from time to time as may seem desirable. The committee will be glad to assemble and correlate any comments of this nature that may be offered.

# New Radio Tube Has Attractive Characteristics

Putting into apparently successful practical application the results of several independent research efforts, a new radio tube of interesting characteristics recently has been brought into the market. Known as the "Wunderlich Tube" this device is specially designed to serve as a high quality detector which combines full-wave rectification with a stage of audio amplification and provides also, all within one tube structure, the necessary voltage for the automatic control of sensitivity.

This new tube may be described as a coplanar grid tube in which grid rectification is obtained by employing 2 grids as the 2 anodes in a full-wave rectifier circuit, while these grids act in parallel to amplify the rectifier audio-frequency voltage, developed across the grid leak and grid condenser. The coplanar grid arrangement increases the power handling capacity of the grid-leak detector by giving greater output and also permitting the development of a voltage sufficient for automatic volume control purposes. The tube, of course, is distinctly different, both in construction and operation, from any of the other tubes now commercially available. It may be thought of as being an ordinary 3-electrode tube to which there has been added a second grid wound between the meshes at the usual grid, and developed in this instance to give a combined power detector and automatic volume control tube all in one. The detecting action is of the power-grid rectification type and, because of the coplanar arrangement, is able to deliver approximately twice as much undistorted output as can the ordinary triode type of grid rectifier. The volume control function is said to be performed without interfering in any way with the tube's primary function as a detector. Experiments seem to show that various control groupings can be arranged depending upon the characteristics of the particular circuit in which the tube is to be used.

The tube derives its name from Norman E. Wunderlich (A'27) of Chicago who, in cooperation with the Arcturus Radio Tube Company of Newark, N. J., has sponsored this first commercial coplanar grid type of vacuum tube to be placed upon the

American market. Some details pertaining to earlier efforts to develop a commercial type of coplanar grid tube are described in a paper, "A Study of the Output Power Obtained From Vacuum Tubes of Different Types," prepared by H. A. Pidgeon and J. O. McNally (A'26) which may be found on p. 266 of the February 1930 issue of the *Proceedings* of the Institute of Radio Engineers. Experimental and theoretical data supporting the contention that satisfactory power grid leak detection could be obtained were given in a paper, "Some Properties of Grid Leak Power Detection," prepared by F. E. Terman (A'23) associate professor of electrical engineering at Stanford University (California) and N. R. Morgan, then a graduate student at Stanford. This paper may be found in the December 1930 *Proceedings* of the I. R. E. The Wunderlich tube is the first commercial development to make use of these works and its evolution shows a serious attempt to develop a new tube capable of performing the functions for which present day receivers require 2 tubes.

# "Nothing More Modern"

**Electrical features of the Philadelphia Saving Fund Building include unusually high artificial illumination and complete air cooling and conditioning equipment, serving the entire building. The installation involves some unique designs and new applications of engineering materials. Owners, architects, and engineers have cooperated to secure a highly modern and practical structure.**

By
**C. D. FAWCETT**
MEMBER A.I.E.E.
Associated with Howe and Lescaze, architects, and with H. Berkeley Hackett, consulting engineer, Philadelphia, Pa.

THE OLDEST savings bank in America, the Philadelphia (Pa.) Saving Fund Society, now is completing construction of a new 33-story bank and office building of the most modern functional design in America. With electrical and mechanical equipment selected to provide extensively for the comfort and convenience of its occupants, the building provides: elevator service 20 per cent faster than found in typical similar structures; for natural lighting efficiency, an outside wall area 65 per cent glass; for artificial lighting efficiency, an indirect system providing on all normal working planes an evenly diffused non-glare illumination of 19 ft-c; for exterior decorative effects, floodlighting near the ground, panel lighting near the roof, and a 27 × 120-ft neon sign on the roof; for the health and comfort of those in the building a complete recirculating air cooling and conditioning system, with full temperature and humidity control. Communication, alarm, and signal systems installed provide extensive facilities for telephone, radio, television, telegraph, stock ticker, telautograph, and synchronous time services. It is contemplated that the building will stand as a creditable monument to its owners, architects, and engineers, as an exemplification of their design slogan, "Nothing more modern."

Electric service to the building is supplied over 2 13.2-kv 3-phase 60-cycle circuits from independent sources. Two isolated sections of 13.2-kv bus and duplicate low voltage buses for power and light distribution are designed to operate normally with half of the entire building load on each of the 2 incoming high voltage feeders, with arrangements to interconnect automatically the 2 sections of the high voltage bus in the event of the failure of either feeder. The control facilities provide for manual rather than automatic restoration of normal service conditions after automatic transfer. Automatic interlocks on both the high voltage and low voltage circuit breakers prevent inadvertent paralleling of the 2 main service feeders. For extreme emergency conditions, full manual control may be established through a master release which makes the normal interlocking features inoperative. Since local system volt-

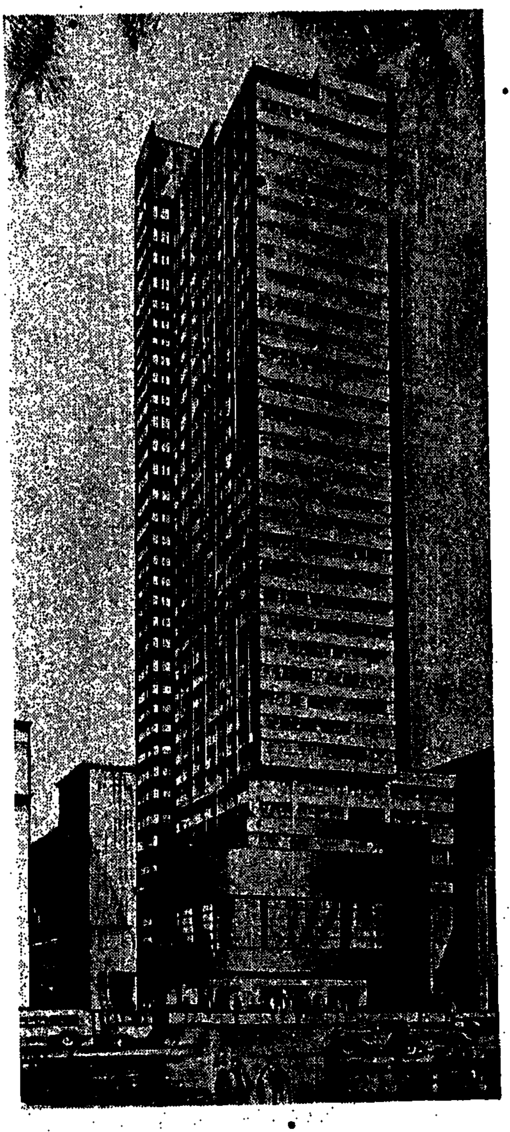

Fig. 1. Architect's drawing of "America's most modern" commercial structure, the 33-story bank and office building of the Philadelphia Saving Fund Society

---

Written especially for ELECTRICAL ENGINEERING by Mr. Fawcett, who in addition to his consulting activity is professor of electrical engineering at the Moore School of Electrical Engineering, University of Pennsylvania, Philadelphia, Pa. *Not published in pamphlet form.*

age regulation is very good, no regulators were installed, 2 2.5 per cent taps above and below the normal 13.2-kv connection on each of the main transformers being supplied for possible future changes in nominal voltage values.

In the sub-basement substation, a 3-section semicircular duplex control board centralizes the control and metering for all circuits. The outside sections of the board carry triplex ammeters, respectively, for the power and the lighting feeders; the center section carries a dummy bus with a complete complement of pilot lights and control switches for operating all high voltage switches and the bus-tie and inter-bus emergency transfer switches, all necessary ammeters, wattmeters, power factor meters, totalizing graphic wattmeter, and graphic voltmeters for the power and light buses. The rear doors of the panel boards carry associated relays and test blocks, and also give access to the wiring. For all control wiring, multiple-conductor colored control cable is used, housed in accessible wire-ways placed at the top of the switchboard sections to protect against possible damage from flood waters.

Power for all service motors and elevators throughout the building is distributed over 3-wire 3-phase 60-cycle circuits at a nominal rating of 440 volts, whereas lighting equipment is fed from a nominal 199–115-volt 3-phase 4-wire 60-cycle grounded-neutral system. An auto-transformer is provided for the emergency transfer of energy between the light and power buses in the event of failure of one of the main transformers. Color identified wires and cables are used throughout the building for all low voltage feeders, subfeeders, and branch circuits for both light and power. Two special elevator feeders run the full height of the building, each with taps at the 20th floor for the low rise elevators, and at the 33rd floor for the high rise elevators. Each elevator feeder has copper capacity sufficient to serve all elevators, and switching facilities to provide for the transfer of any elevator to either feeder and hence to either of the building services. An excellent opportunity thus is provided for balancing power loads, for balancing power factor on the service feeders, and for inspection and maintenance requirements. In addition to the 2 elevator circuits there are 9 power feeders and 9 lighting feeders, and provisions for one spare feeder for replacing any defective lighting feeder. All circuits for the lighting system, including the transformers, have been designed and installed for a capacity approximately 50 per cent greater than the present connected load.

An interesting departure from common practise is presented in the design used in both low voltage bus feeders and in the corresponding distribution risers

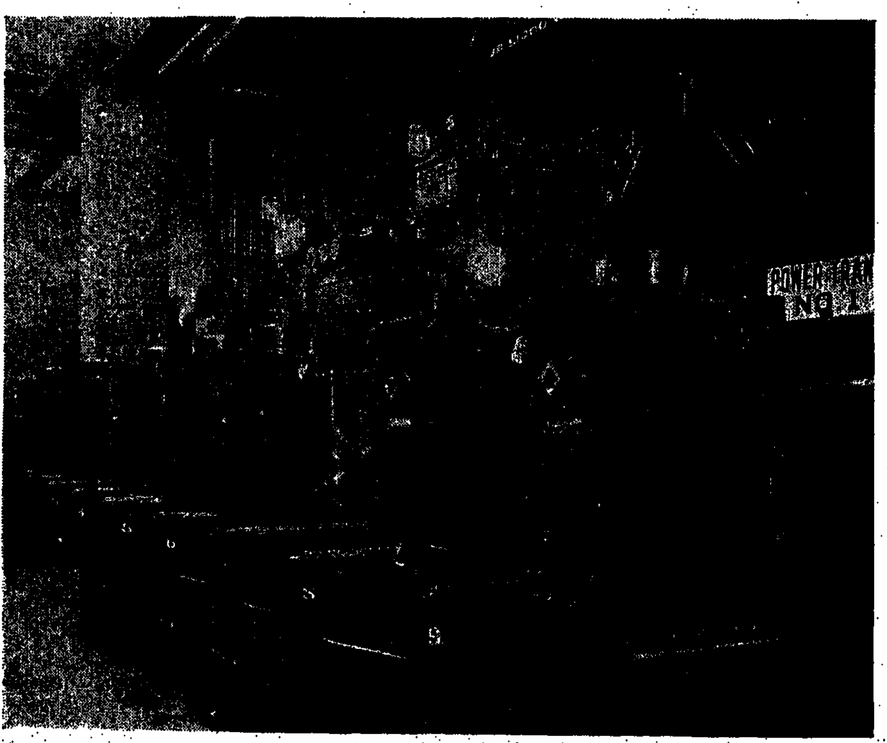

Fig. 2. Seven metalclad oil circuit breakers serve the 13.2-kv bus, 2 for incoming service lines, 2 for power supply, 2 for lighting supply, and one service bus tie

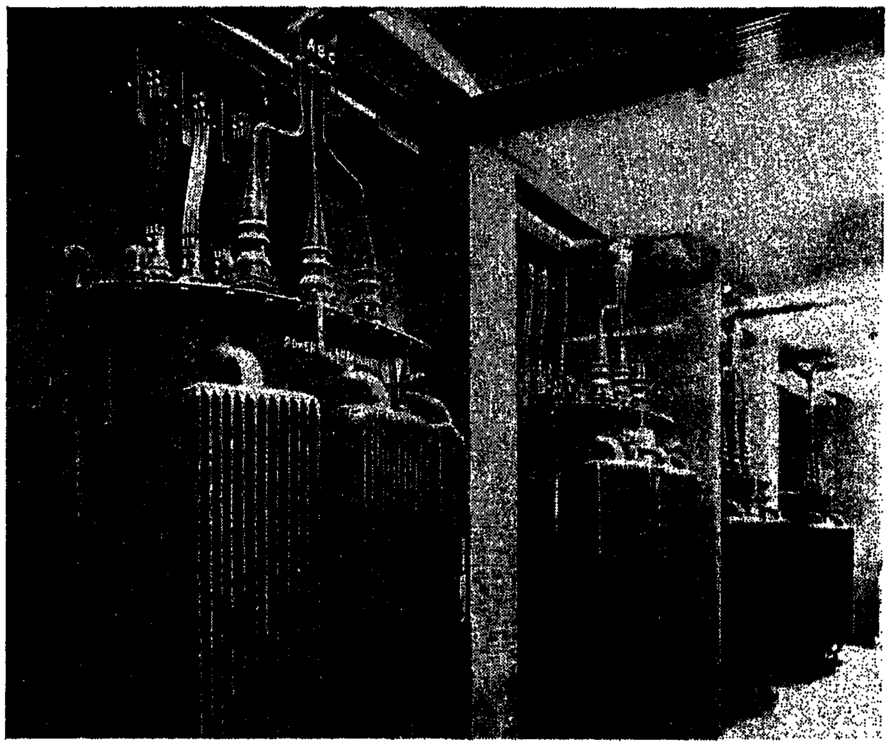

Fig. 3. Oil-insulated self-cooled transformer equipment includes 2 1,200-kva 3-phase units for power supply, 2 750-kva 3-phase units for lighting supply, and one 750-kva 3-phase auto-transformer unit (not shown) for emergency interconnection between the 440-volt power buses and the 115–199-volt 4-wire lighting buses

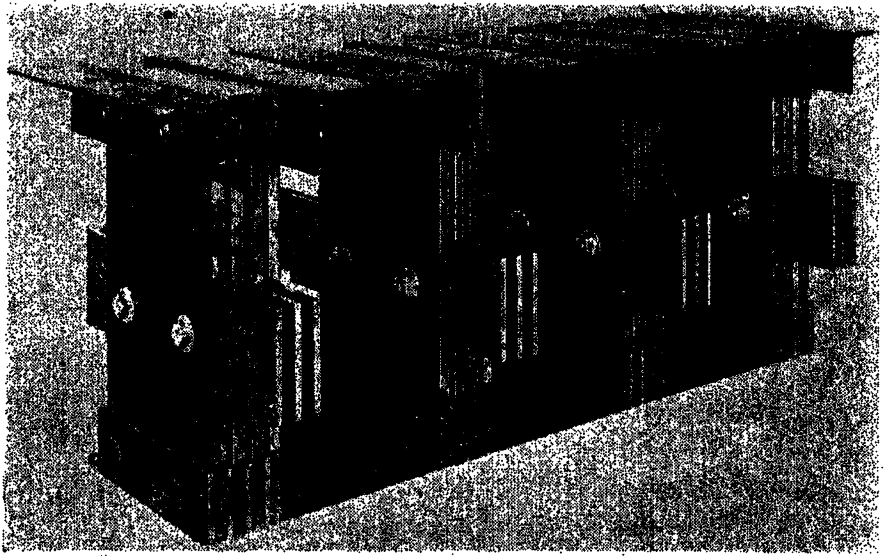

Fig. 4. The use of sheet insulation in the bus assemblies speeded construction, simplified expansion problems, proved no more costly than the more usual types of construction and will expedite inspection and repair

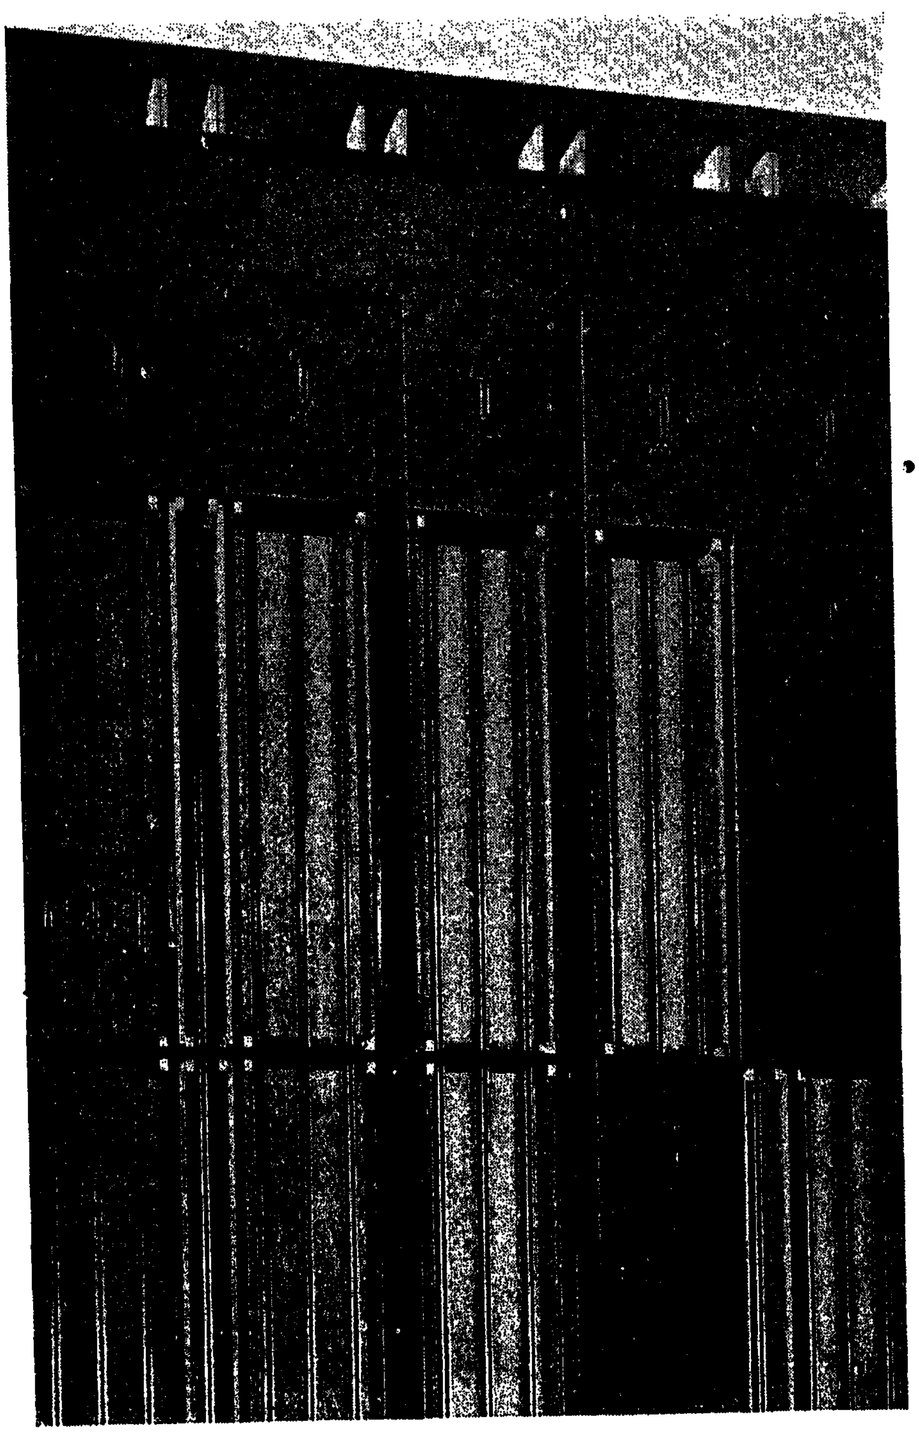

Fig. 5. Steel feeder compartments for the wire shaft which extends the entire height of the building were factory-made in sections for each floor span. Feeder conductors consist of 2 1/4 × 2-in. flat copper strips per phase, designed for a current density of 800 amp per sq in., and supported and spaced by sections of sheet insulation. For tap-offs, special connection boxes fitted with suitable outlets are substituted for the plain covers shown

through the building. In both instances, flat copper strap of convenient proportion was used, spaced, insulated, and supported by flat sheets of composition insulating material. An example of this construction as used in the main low voltage buses may be seen in Fig. 4, where it may be noted also that the supporting sheet insulation is mounted by means of bolts sliding in slotted angle iron pieces which in turn are bolted to the concrete floor slabs. This latter construction is used for long runs and, with flexible cable connections at the ends of the runs, takes care of all temperature expansion and contraction in the bus copper. Electrical and mechanical tests have indicated high factors of safety under both dry and wet conditions.

A related type of construction is used for the main vertical distribution circuits as indicated in Fig. 5. The steel raceways carrying these circuits line the wire shaft on 2 sides from the sub-basement to the 32nd floor. In these steel feeder compartments the flat copper conductors are guided and spaced by sheet insulation spacers located every 4 ft, and the weight is supported by vertical sheets of insulating material. Each phase of bus-bar feeder is supported at the middle of a 120-ft vertical section by one of these sheet-insulation supports, and the expansion is upward and downward from that fixed point. Woven copper straps, surrounded with composition phase-spacers take care of the expansion between these sections.

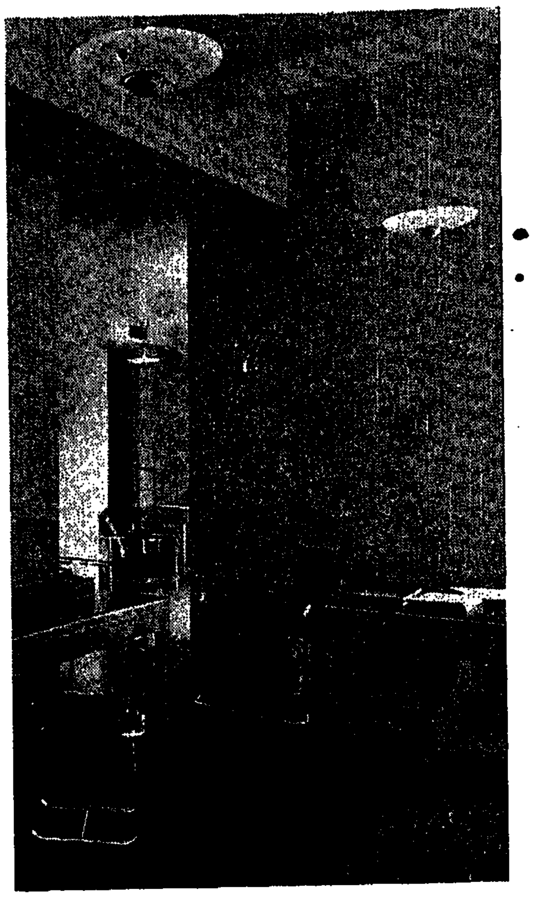

Fig. 6. Lighting fixtures are severely simple in contour and finish, and economical in first cost and maintenance. They use 200-watt silvered-bowl processed lamps hung 40 in. below the ceiling on 8 1/2 to 9 1/2-ft centers

Over the entire length of the wire shaft compartment covers are removable and tap-off feeders are housed in enclosing boxes which fit into the spaces otherwise normally occupied by the compartment covers, thus providing convenient connection at any desired point. Between the adjacent steel feeder compartments there exist, as a "by-product" of the design, wire raceways approximately 3 × 6 in. in cross-section in which low-capacity rubber-insulated cables and control wiring for various building services are installed. The whole design is safe, fireproof, compact, easily accessible for inspection and repair, economical in first cost, and readily capable of expansion in copper capacity and extra tap-offs without loss of existing materials.

The principal features of illumination in the building, as already mentioned, include relatively high intensity of interior illumination and the neon sign of spectacular proportions on the roof. The exceptionally fine lighting effect with the 19 ft-c of evenly diffused light is secured by the simple unit shown in Fig. 6. To eliminate glare and specular reflection, the light gray walls and white ceilings are painted with a non-gloss finish.

The neon sign on the roof of the building about 500 ft. above the sidewalk is one of the largest in the United States. Each letter is 27 ft high, 9 in. in depth, 15 ft wide, and has a 22-in. stroke. The letters are supported in free space 30 in. in front of a solid metal plate background which spans 120 ft in a horizontal direction. The letters are of simple block form, painted white and with porcelain enamel face; the background is a deep cobalt-blue. Approximately 1,000 ft of 12-mm 30-ma neon-filled tubes are used to provide illumination at the center of the letter strokes. Visibility and tube light output tests now being conducted may alter somewhat the ultimate tube specifications. It is expected that the sign may be read from a distance of 3½ miles at night and 3 miles in the daytime.

In summarizing some of the outstanding electrical features of this building it is of some interest to note that some 64 per cent of the building motor load is required for the air conditioning and circulating equipment, in addition to the motors installed as spare units. Other pertinent data are given in the following tabulation:

| | | |
|---|---|---|
| Total connected motor load (exclusive of spare units) | | 3.620 hp |
| Elevator load | 1,046 hp | |
| Air-conditioning load | 2,310 hp | |
| Domestic water system | 121 hp | |
| Heating system (for condensate, etc.) | 41 hp | |
| Miscellaneous applications | 102 hp | |
| Total connected motor load (approx.) | | 3,100 kw |
| Total connected lighting load | | 1,676 kw |
| Grand total connected light and power load | | 4,776 kw |
| Total over-all volume of building | | 7,977,000 cu ft |
| Total over-all floor space | | 562,680 sq ft |
| Space rented by P.S.F.S. (owners) | 62,900 sq ft | |
| Office space, rentable area | 328,510 sq ft | |
| Store space, rentable area | 35,140 sq ft | |
| Non-rentable area | 136,130 sq ft | |

# Researches in Arc Welding

**Research of extreme importance in the field of electric welding is reviewed briefly in this progress report. Laboratory tests have demonstrated the impossibility to strike an arc with 120 volts between pure iron electrodes in an atmosphere of pure argon, an observation that may require the modification of basic conceptions of the nature of the electric arc discharge.**

IN INDUSTRIAL electric arc welding it is often difficult to say, once good or bad results have been obtained, just why they are good or why bad, and if bad just which of the dozen or more variables in the process was responsible. Obviously many inferior welds are being made in this maze without leading to any definite conclusion. Some of the variables are:

1. Kind of steel welded—that is, the chemical composition, heat treatment, amount of included matter, and surface condition of the parts welded
2. Kind of electrode wire used
3. Preparation of parts prior to welding
4. Kind of welding machine used
5. The human element in the operator's work
6. Subsequent heat treatment of weld
7. A host of others.

It has been proposed that this admittedly complex but industrially important problem be studied by statistical methods in which each variable in every welding operation, together with the degree of success of the operation, be recorded on a series of cards which could then be sorted and the rôle of each variable so evaluated. The other obvious method of attack is the method of abstracting the basic simplified system from the usual complex system; such as using *pure* iron for electrodes and for the parts to be joined, and performing the welding in an inert and therefore non-participating atmosphere. This latter is the method adopted by the present authors and supported by the A.I.E.E. through a grant from Engineering Foundation in 1930, and supported also by Lehigh University.

The successful completion of this project should establish a base line both for the behavior of arcs and for the qualities of welds of pure iron in a non-participating atmosphere. Once the characteristics of an iron arc are known, and once the physical, chemical, mechanical, and metallurgical properties of pure iron welds are established, all more complicated alloys such as commercial steels then could be referred to that base line as a standard, and a judgment could be made of the effects of each alloy element, whether desirable or undesirable. Thus, questions such as: "What should be the phosphorus or sulfur content of steel for welding? Is nitrogen in steel detrimental for welding? What about the best composition for welding wire? What is the action of air on the arc and on the weld metal?" today unanswered, could gradually be answered by reference to the pure iron base line, and the wastefulness and uncertainty of guessing eliminated.

## Purity of Materials

Pure iron in the form of wire $^1/_8$ in. in diameter and plates $^1/_8$ in. thick was contributed for these studies. A special method was followed in the preparation of these experimental samples from ferrous chlorid ($FeCl_2$) of reagent grade. This material analyzed as follows:

| | |
|---|---|
| $SO_3$ | 0.0005 per cent |
| As | 0.0000 per cent |
| Cu | 0.0000 per cent |
| Zn | 0.008 per cent |

---

Specially prepared for ELECTRICAL ENGINEERING; includes the essential substance of a progress report presented informally before the welding session of the A.I.E.E. 1932 winter convention, the substance of important discussion arising from that presentation, and the results of subsequent research. *Not published in pamphlet form.*

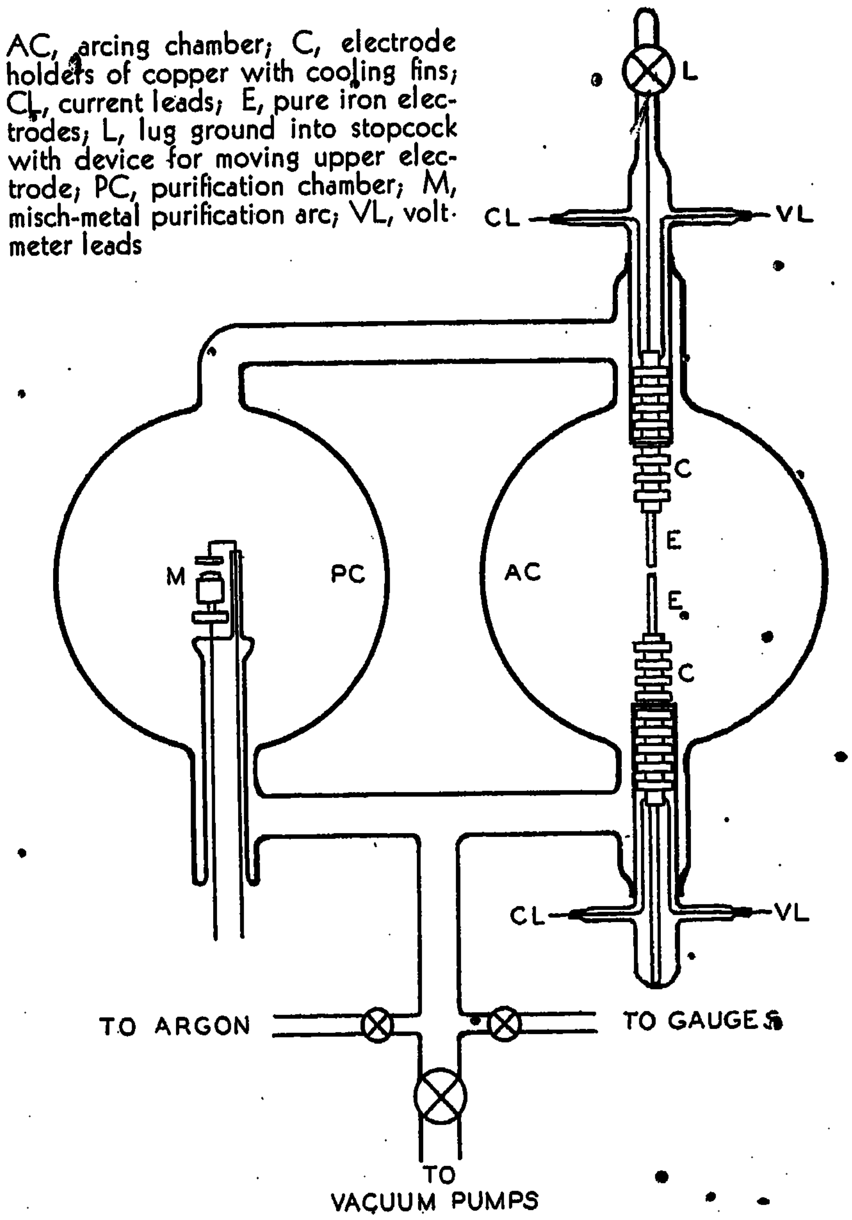
It then was partially converted to oxid by heating in a porcelain dish in an oven. Decomposition was completed by adding chemically pure concentrated nitric acid ($HNO_3$) and reheating in an oven. The ferric oxid ($Fe_2Cl_6$) thus produced was reduced in hydrogen in a porcelain tube to give metal powder. After that, the powder was sintered and drawn into a wire, and finally heated in a tungsten grid vacuum furnace.

Argon gas with total impurities amounting to only 0.0003 (30 parts per million), the purest gas obtainable in quantity, was used for the experiments. The arc chamber, *AC* in Fig. 1, was made of pyrex glass, as also was the auxiliary purification chamber *PC* and all connections. The auxiliary chamber contained a second arc, supplied by a separate 500-volt circuit. The arc in this chamber had misch metal (reactive metals such as cerium or lanthanum) as one electrode. With such an electrode, the metal which vaporizes from it reacts with any reactive gases in the argon and the compounds so formed deposit on the walls of the chamber. This has been reported upon in some detail by Dr. Saul Dushman in the Franklin Institute *Journal* for June 1931.

## ARCS IN ARGON

In tests made with argon gas as received, in moist air and in dry air, all metal parts except the iron wires, but including the copper grips *CC* and the glass chambers, were baked out previously in a hydrogen furnace to expel gases. The chambers then were exhausted, filled with argon, again exhausted and filled, and the arc struck between electrodes *EE* by turning the ground glass lug *L*. Runs made without operating the misch metal arc further to purify the argon gas as purchased, gave a normal arc discharge at *EE* with an impressed potential of 120 volts. The results so obtained, while valuable, were not especially noteworthy. The length of the arc was measured by projection onto a screen; the current and voltage by Weston standard laboratory meters. The results are shown in the characteristic curves in Figs. 2 and 3. Currents higher than 2.5 amp could not be used without consumption of the electrode. For comparison with the argon, similar runs were made in slowly circulating dry air and in circulating moist air. These characteristic curves for dry air and for moist air arcs of pure iron are included in Figs. 2 and 3.

As Fig. 2 shows, the arcs in air, both dry and moist, require a substantially higher voltage than the arc in argon. Also, the arc in air cannot be extended to such lengths as the arc in argon, which latter goes to 9 mm without extinction. In most cases the voltage of arcs of a given length in dry air are lower than in moist air, as reported also by Shrum and Wiest at the 1931 winter convention of the A.I.E.E. (A.I.E.E. TRANS., v. 50, June 1931, p. 650–5). Both 1-amp arcs show irregularly high voltages indicating probably that the arc was in transition between the first and second arc stages. Further information concerning this may be found in papers by S. Maisel (*Phys. Zeit.*, v. 550, 1904); C. P. Steinmetz (*Trans.* Elec. Cong., St. Louis, v. 2, p. 704, 1904); Cady and Arnold (*Am. Jl. of Science*, v. 24, p. 383, Nov. 1907). At 4 mm the dry air arc curves of Fig. 3 show breaks at all currents. No explanation for this irregularity is offered at present. In other respects the curves in



AC, arcing chamber; C, electrode holders of copper with cooling fins; CL, current leads; E, pure iron electrodes; L, lug ground into stopcock with device for moving upper electrode; PC, purification chamber; M, misch-metal purification arc; VL, voltmeter leads

**Fig. 1. (Above) Apparatus used for the determination of the characteristics of arcs drawn between pure iron electrodes in an atmosphere of argon gas**

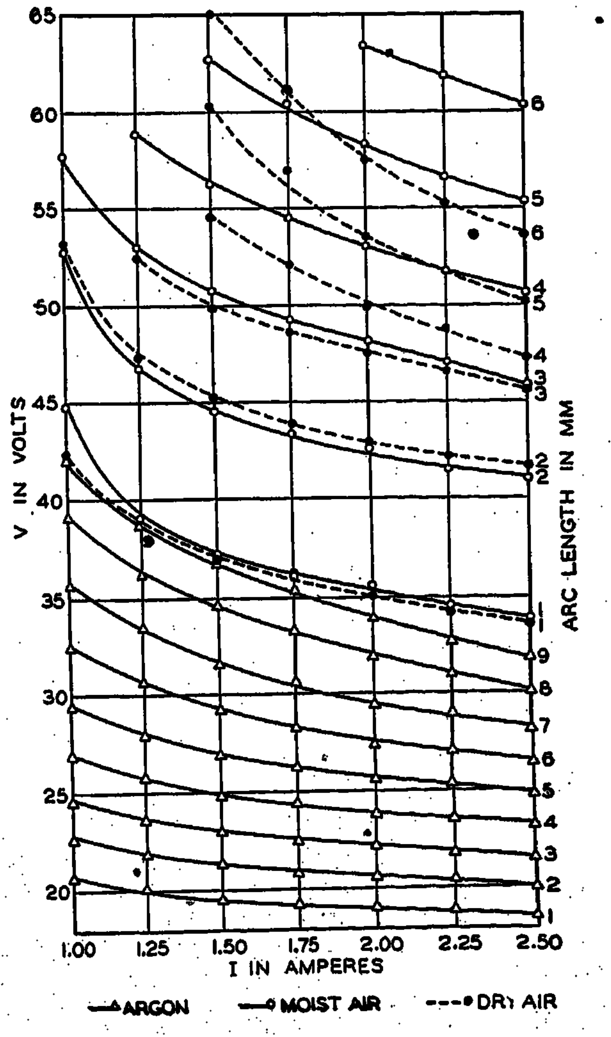


**Fig. 2. (Right) Comparison of the voltampere characteristics of the iron arc in argon gas, moist air, and dry air**

air and those in argon are quite regular. The 1-mm curve in argon is approaching rapidly the condition of constant minimum voltage, independent of arc current.

The arc in argon deposited a black coating on the chamber, probably condensed iron vapor; in air the deposit was of a brownish red color like iron oxid. The arc was difficult to strike at first when new electrodes were used in dry air, but not so in moist air.

Both the arc in argon and in moist air satisfy W. B. Nottingham's equation

$$V = A + \frac{B}{I^n} \text{ with } n = 2.62 \times 10^{-4}T$$

(where $T$ is the boiling point of the anode) as given in the A.I.E.E. JOURNAL for Feb. 1923, p. 302.

## ARC IN DRASTICALLY PURIFIED ARGON

The most astonishing results came when a final drastic purification of the argon as purchased was carried out by circulating it through the misch-metal-arc purification chamber for several hours before the iron electrodes $EE$ were touched. In these runs the greatest care was exercised to obtain absolute cleanliness. An entirely new glass system and new iron electrodes were used each time. All parts (except the iron) were thoroughly baked out in the furnace prior to use. After circulating the argon for several hours (by convection) between the purification chamber and the arc chamber proper, the electrodes $EE$ with a potential of 120 volts across them were touched and slowly separated. In all cases, however slow and cautious the separation, no arc could be struck. It was simply *impossible* to strike an arc between the pure iron electrodes with 120 volts in an atmosphere of *pure* argon.

The implications of this result are far reaching. It has never been supposed previously that an arc required for its establishment a complex atmosphere, or one containing chemically active gases such as the nitrogen and water vapor which constituted most of the 30 parts of impurity in 1,000,000 parts of "impure" argon as received. The low voltage electrical discharge through gas or vapor (i. e., the arc discharge) has been explained by Dr. K. T. Compton (*Phys. Rev.*, v. 21, p. 266, 1923) on the basis of thermionic emission from a hot cathode, and by Dr. Irving Langmuir (*G. E. Rev.*, v. 26, p. 735, 1923; *Science*, v. 58, p. 290, 1923) from the accumulation opposite the cathode of a positive space charge which pulls electrons out of the cathode, whether hot or cold. Most arcs can be accounted for successfully by one or the other theory. Neither theory postulates the necessity for the presence of chemically active atoms or molecules in the arc environment, and yet the refusal of the arc to form in the pure gas used in the experiments here reported indicates this new view. Arcs in argon have been reported frequently in the past, but never in a gas so highly purified as in the present studies. It is possible that our most basic conceptions of the nature of the arc discharge may require modification to conform to these observations of the iron arc in argon.

If the rigorousness of the purification were relaxed in the slightest degree—if, for example, the surfaces of the iron electrodes were not scrupulously cleaned immediately before insertion into the chamber—the normal arc would strike without difficulty; or if the copper grips $CC$ were not baked thoroughly, a discharge between the lower grip (copper) and the upper electrode (iron) about $1^1/_2$ in. long would set in, and after a minute or so return to the electrode tips as a normal iron arc. In the tests which revealed this possible condition apparently enough gas had been liberated from the impure copper grip to support the arc in the then contaminated argon gas. However, when purification was carefully prosecuted and complete it was impossible to strike an arc in any one of the 4 glass systems built.

## HYPOTHESES TO EXPLAIN NON-ARCING

Hypotheses to explain this new characteristic of the arc, at least for the iron arc in argon, were offered following presentation of these results at the 1932 A.I.E.E. winter convention by Dr. K. T. Compton, Dr. Saul Dushman, and Dr. Joseph Slepian. Because of their considerable theoretical interest, these hypotheses are stated in the following paragraphs.

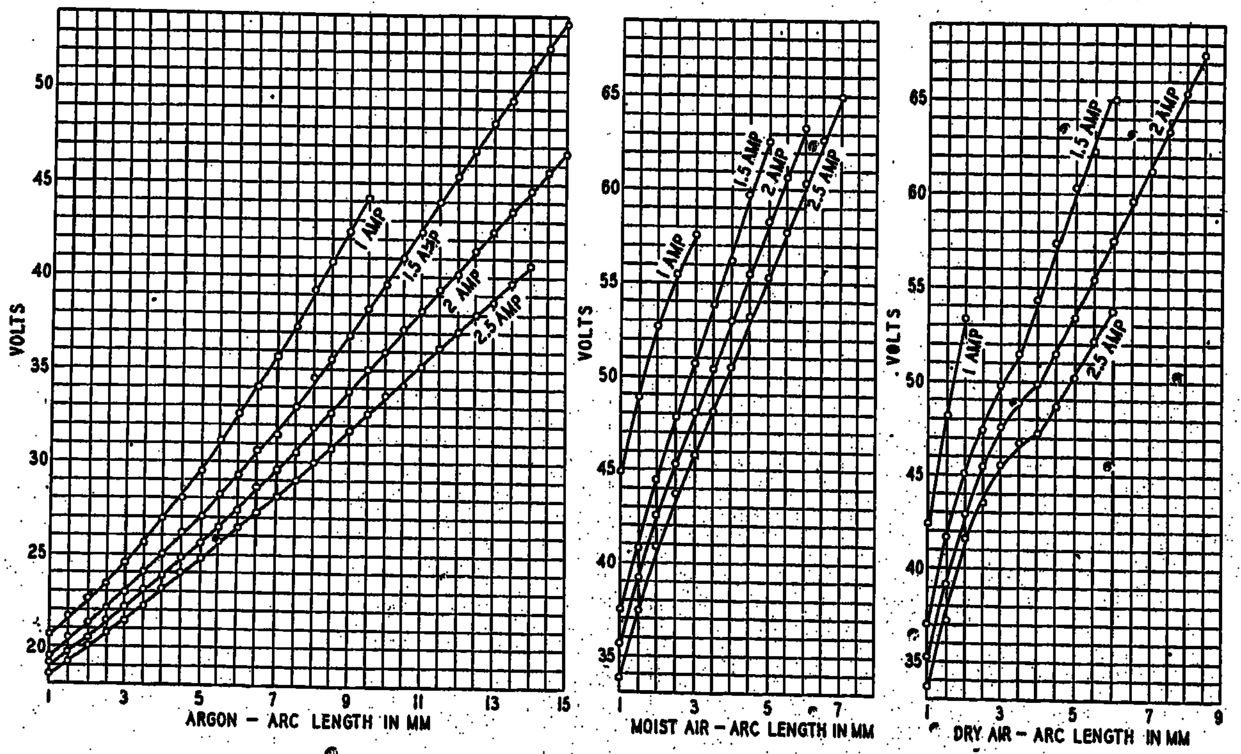

**Fig. 3. Comparison of the voltage-length characteristics of arcs drawn between pure iron electrodes in an atmosphere of argon gas with impurities present (left); in moist air (center); and in dry air (right)**

In commenting on the inability to obtain the normal arc under these "drastically purified" conditions, Dr. Compton in a private communication suggests that possibly an oxid layer on the cathode is a prerequisite in maintaining the proper cathode temperature (in accordance with the thermionic emission theory of the arc). Such an oxid layer might raise the cathode temperature by virtue of its electrical resistance or its thermal insulating properties. Compton further suggests that the elastic electron impacts with argon molecules might so scatter the current over the cathode as to make impossible the establishment of a cathode spot.

Dr. Dushman in a private communication, also considering the arc in terms of thermionic emission, remarks that a thin film of iron on an oxid surface of the metal has a far greater thermionic emission than has the uncontaminated metal surface itself. He is undertaking new experiments in a study of such effects.

Dr. Slepian discussed the subject before the convention in the light of Langmuir's space charge theory. For low current arcs, such as used in the present experiments, the positive space charge just outside the cathode is very small. Consequently, the lines of force of such a charge are spread out so widely that the electric field between the space charge and the cathode is weakened materially. If the field strength drops below a certain value, it is impossible for electrons to be "pulled out" of the cathode, and hence the discharge cannot be supported.

Because of the indicated basic nature of the discovery, these experiments are being continued as part of a comprehensive program, both in America at Lehigh University and abroad in Berlin whence the junior author of this report has gone to continue certain phases of the work. It is contemplated that a complete, detailed report on the studies of the pure iron arc in argon may be published soon by the American Welding Society. Concurrently, the efforts to determine the properties of pure iron welds are being continued; welds of pure iron and also welds of commercial steel have been prepared in "impure" argon and in air. The chemical, physical, mechanical, and metallurgical properties of these welds now are being ascertained.

# Electrical Operation on the Great Northern

**To eliminate a circuitous mountain crossing which had become the "bottle neck" of the line, the Great Northern Railway built a tunnel almost 8 miles long, relocated 17 miles of track, and electrified 73 miles of line. Some of the operating experiences and savings effected in the 3 years since electrical operation was begun are outlined in this article.**

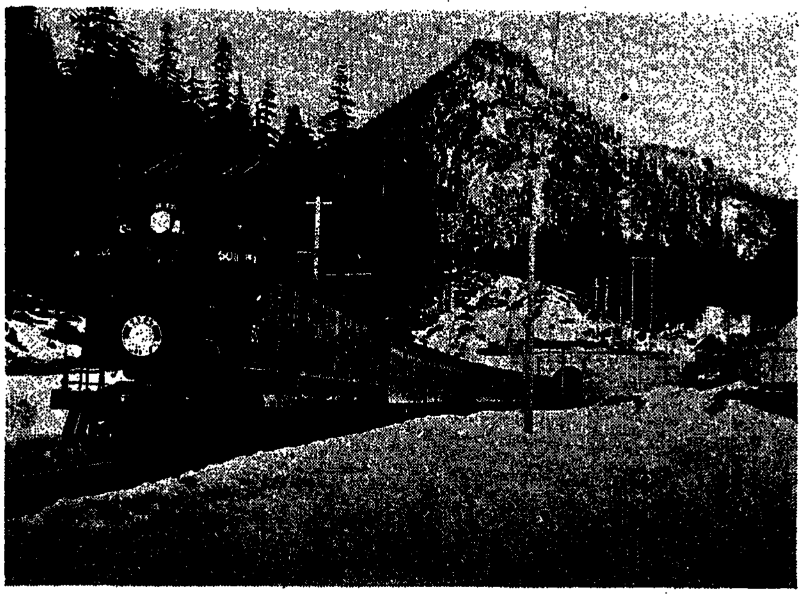

Fig. 1. Locomotive and train leaving western end of new Cascade tunnel

ELECTRIFICATION of the Cascade Division of the Great Northern Railway main line between Skykomish and Wenatchee, Wash., has doubled the capacity of that portion of the line and has resulted in many operating advantages. The electrification, which embraces a total of 73 route miles, was carried out in conjunction with the building of a new tunnel 7.79 miles long, and the relocation of approximately 17 route miles of troublesome track and other minor improvements, aggregating the total expenditure of approximately $25,500,000. All of these improvements were placed in operation at about the same time so that there has been no opportunity to make a direct and segregated comparison of operating expenses that would indicate definitely the advantages of each improvement separately. The new tunnel represented the second undertaking of that nature in the history of the Great Northern Railway's route across the precipitous Cascade range.

The original route, which was placed in operation in 1893, went over the range through Stevens Pass at an elevation of 4,059 ft. It was possible to keep the maximum grade at 2.2 per cent up to 3,382 ft on the

---

eastern slope, and to el 3,126 ft on the western slope. These points were approximately 2.7 miles apart by direct line through the mountain or 4.5 miles over the pass. A tunnel between these points was considered at the time, but it would have cost more and taken much longer to tunnel than to build the road through the pass, two very important items in those days; consequently the line was built through the pass. This was done by increasing the ruling grade to 4 per cent and resorting to an 8-point switchback, involving approximately 12 miles of track. As had been foreseen, this switchback became the proverbial "bottle neck" of the line and with the natural increase of traffic, its capacity soon was reached. This was particularly so during the winter months when there was apt to be an aggregate fall of from 50 to 100 ft of snow at a rate as high as 8 to 10 in. per hr at times.

To overcome these difficulties and to improve the service, the construction of a 2.63-mile tunnel was begun in 1897. This tunnel which was placed in operation in 1900 ran in a straight line at a constant grade of 1.695 per cent eastbound, cut out the entire switchback, and eliminated 2,332 degrees of curvature and all grades in excess of 2.2 per cent. This improvement shortened the route approximately 9 miles which reduced the running time of all trains about 2 hr with a corresponding decrease in operating expenses.

## First Tunnel Electrified in 1909

With a further increase in traffic the ventilation of this tunnel became so unsatisfactory with the operation of coal burning steam locomotives that the tunnel and tracks at each end were electrified. The 3-phase system was selected for this installation largely because of its ready adaptation to regenerative braking. It was the first and only application of this system in America, as well as the first regenerative braking on a steam railroad. (See "The Electric System of the Great Northern Railway at Cascade Tunnel," C. T. Hutchinson, A.I.E.E. Trans., v. 38, 1909, p. 1281.)

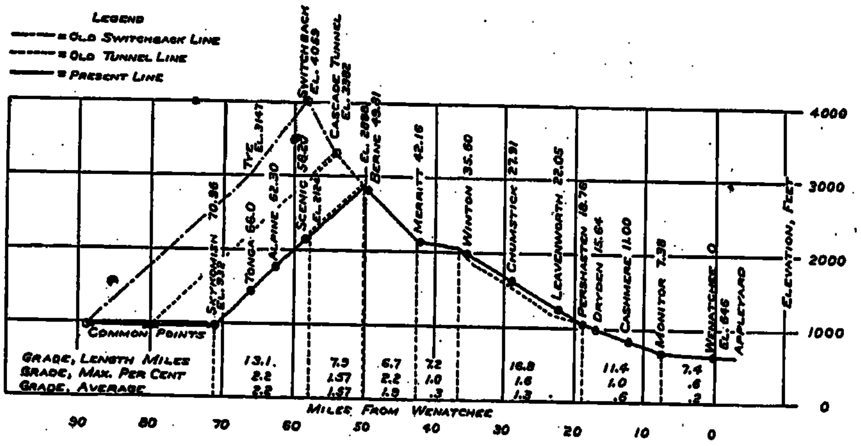

Fig. 2. Condensed profile of the old and new routes over the Cascade range.

Table I—Comparison Between Old and New Lines

| | Old Line | New Line | Advantages of New Line |
|---|---|---|---|
| Length in miles | 17.67 | 9.99 | 7.68 |
| Maximum curve, deg | 10.00 | 6.00 | |
| Total curvature, deg | 2,128 | 187 | 1,941 |
| Maximum grade, % | 2.2 | 2.2 | |
| Tunnel grade, % | 1.695 | 1.565 | |
| Summit elevation, ft | 3,382 | 2,881 | 501 |
| Total rise westward, ft | 546 | 45 | 501 |
| Total fall westward, ft | 1,325 | 824 | 501 |
| Total length of snow shed, miles | 6.04 | | 6.04 |
| Total length bridges, miles | 0.23 | 0.04 | 0.19 |
| Total length tunnels, miles | 3.66 | 7.79 | |

Electrical operation of this tunnel was begun in July 1909. The 3-phase equipment satisfactorily met the original requirements and was continued in service until March 1927 when it was replaced by the present single-phase system. The only notable modification of the 3-phase equipment was the installation of the necessary wiring and switches for a concatenated connection of the traction motors to provide a running speed of $7^1/_2$ mph in addition to the speed of 15 mph originally selected. This was done in the latter part of 1923 when the division point of the road was removed from Leavenworth to Wenatchee (Appleyard) which increased the length of the freight run from 109.3 miles to approximately 132 miles.

At the beginning of electrical operation, the freight trains did not exceed 1,600 tons trailing so that 3 of the 115-ton electric units were used to take this train with the road steam locomotives through the tunnel at one trip. With a gradual increase in train weights it had been found necessary to cut the heavier trains and take them through in 2 trips on account of the limited capacity of the Tumwater power plant; this caused a delay of about an hour. By using the half-speed connection it was possible to use 4 electric units per train and to haul up to 2,200 tons trailing plus the steam road locomotives through the tunnel at a single trip without exceeding the capacity of the power plant.

## Electrification Extended

This lessening of the total number of trips per day left the electric locomotive crews and the power plant idle a greater portion of the time. Consequently consideration soon was given to the extension of the electrification from the west portal of the tunnel to Skykomish, a distance of approximately 21 miles, so that the electric units might be used to replace the steam locomotives used in the helper service on the 2.2 per cent grade up the west slope. A study of this plan indicated that, if adopted, quite a saving in operating expenses should result in addition to some saving in time. There would be practically no increase for electrical operating cost as the extended service would increase only the load factor without adding greatly to the crew hours paid for, and the necessity for the stop at the west portal of the tunnel would be avoided.

In the consideration of this extension it was realized that a new tunnel undoubtedly would be constructed within a few years, involving a new route which would result in the abandonment of at least 9 miles of this proposed extension as well as the old tunnel electrification. It was necessary therefore that the expenditure for the extension be kept at a minimum and that any additional electric locomotives required be capable of use on any desired change of route.

The 3-phase locomotives then in use in the tunnel with their constant speed characteristics and with only 2 operating speeds were not best suited to meet operating conditions on the extension. This fact, together with the complications in the contact system owing to the necessity for the 2 overhead wires, made it unlikely that this system would be chosen if the electrification were extended beyond the mountain section. After careful consideration the single-phase motor-generator type of locomotive was chosen as being best suited to meet all of the existing conditions. This locomotive embodies a combination of the most desirable features of both single-phase and d-c locomotives. The speed can be varied to any degree necessary to conform to either the train weight or available power, or both; this type of locomotive thus is well adapted to operation as a helper to a steam locomotive. For the extension planned, one double-unit class 1 — D — 1 + 1 — D — 1 motor-generator locomotive originally was ordered.

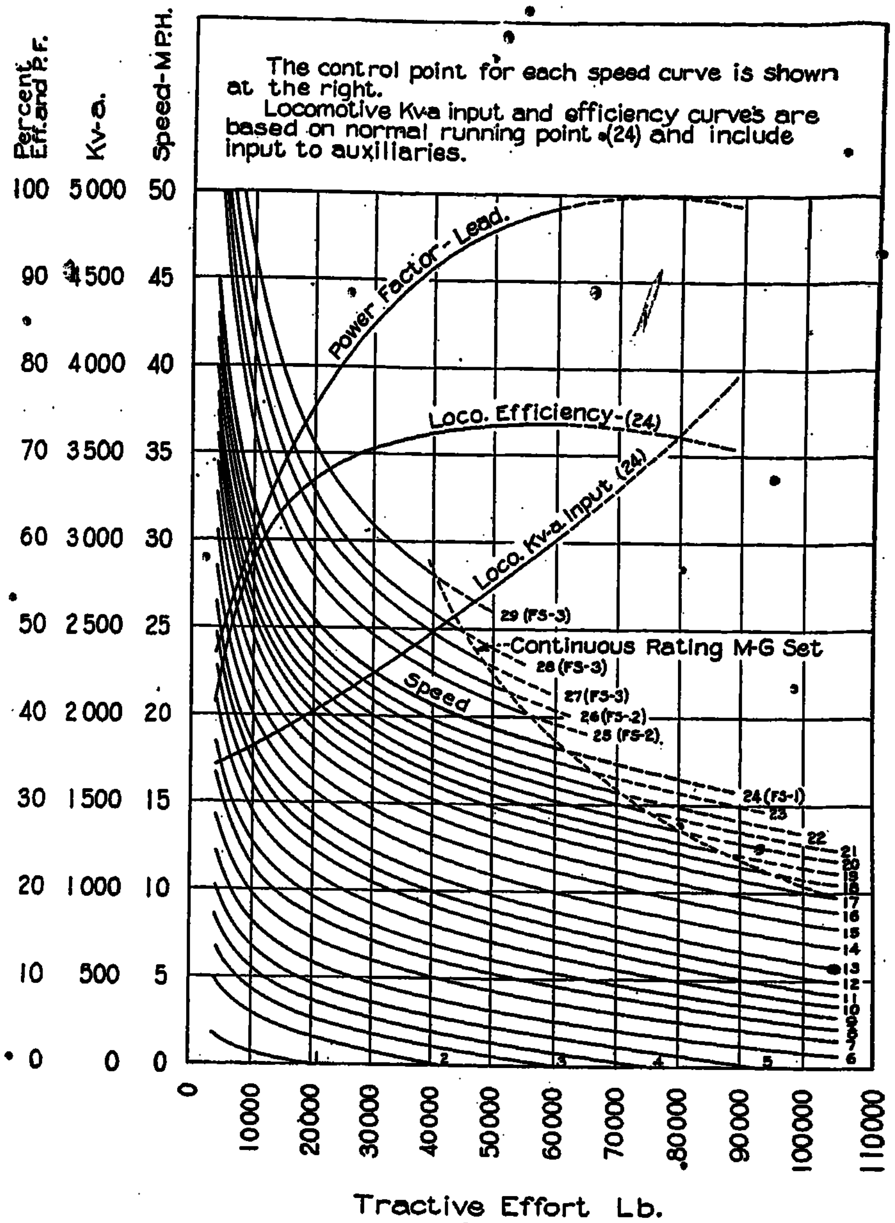
Generators at the power house were of liberal design, having sufficient excess capacity over the water-wheels to permit their operation single-phase. Available capacity at the power house was approximately 4,000 kw.

## NEW TUNNEL AND FURTHER ELECTRIFICATION

A few months after the equipment for this extension had been ordered and before electrification had been completed, a decision was reached to construct a new tunnel 7.79 miles in length. The new route would leave the main line at Scenic on the west slope and join it again at Berne on the east slope, thus substituting 9.99 miles of new route for 17.67 miles of the old route with advantages as indicated in Table I.

The new line would remain below the elevation of heaviest snowfall and would traverse a route less subject to drifts and slides than was the old route. Also a relocation of the line between Winton and Peshastin had been surveyed which would (1) avoid some troublesome line in the Tumwater Canyon; (2) reduce the maximum grade from 2.2 per cent to 1.6 per cent, the maximum curve from 10° to 3°, and the total curvature 1,286°; and (3) shorten the line about $1^1/_4$ miles.

With these revisions of line in view and with a further definite decision to electrify the entire line between Skykomish and Wenatchee and to leave off the steam locomotives between these points, the character of the service was so changed as to make it desirable to consider some revision in the additional motive power required. Between Merritt and Wenatchee over the new route, a distance of 42 miles, the line would permit speeds of 50 mph safely, whereas the line between Skykomish and Cascade Tunnel did not permit speeds in excess of 30 to 35 mph; the new locomotives (class 1 — D — 1 + 1 — D — 1) had been designed accordingly with a maximum safe speed of 40 mph. With only 73 route miles electrified requiring so few locomotives, it was desirable to have all locomotives interchangeable between passenger and freight service and that any locomotive be operatable in the same train with any other locomotive. Regular passenger trains operated over the line varied from 8 to 12 cars, aggregating from 700 to 1,000 trailing tons; freight trains ordinarily would range between 2,500 and 4,000 tons trailing. Grades range from 0.2 to 2.2 per cent, the average up grade for the line being approximately 1.29 per cent (see Fig. 2).



The control point for each speed curve is shown at the right.

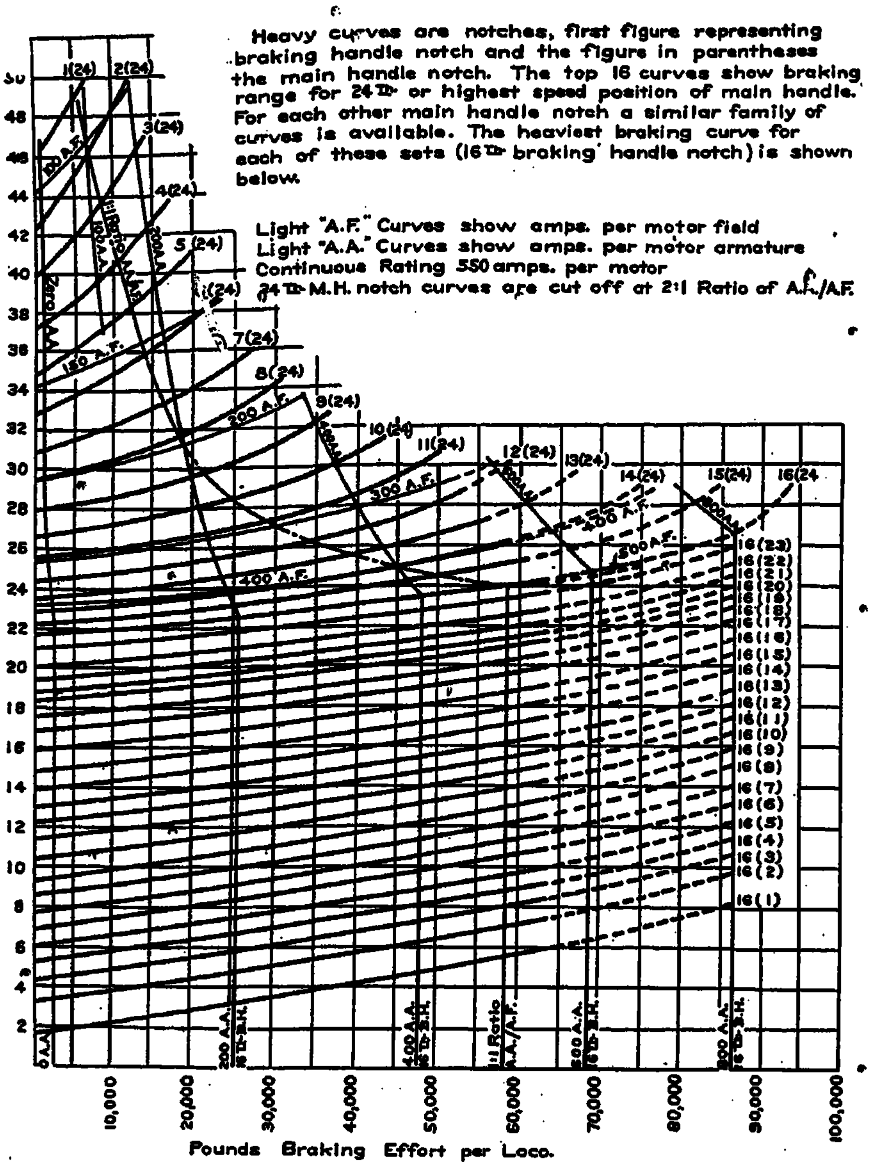
Locomotive Kv-a input and efficiency curves are based on normal running point (24) and include input to auxiliaries.

**Fig. 3. Characteristic motoring curves of the 1 — C + C — 1 10,500-volt 25-cycle locomotive**

## NEW LOCOMOTIVES DESIGNED

To meet these new conditions, a new locomotive known as class 1 — C + C — 1 was proposed, pertinent data for which are given in Table II in comparison with the double unit locomotive (class 1 — D — 1 + 1 — D — 1) for the extension from Cascade Tunnel to Skykomish.

Class 1 — C + C — 1 locomotives, designed particularly for mixed service over the new line, will handle a 1,000-ton trailing train at 18.5 mph on the 2.2 per cent grade and up to about 45 mph on the 0.2 per cent, averaging over the entire up grade portion about 28.6 mph, the average output of the motors being approximately 2,100 kw and the rated load factor, 84 per cent. On the down grades the speed is limited to a maximum of 50 mph. Regenerative features of the locomotive provide satisfactory control of the speed on the varying down grades to meet any conditions imposed by curvature, track conditions, or schedule requirements. Figs. 3



Heavy curves are notches, first figure representing braking handle notch and the figure in parentheses the main handle notch. The top 16 curves show braking range for 24th or highest speed position of main handle. For each other main handle notch a similar family of curves is available. The heaviest braking curve for each of these sets (16th braking handle notch) is shown below.

Light "A.F." Curves show amps. per motor field
Light "A.A." Curves show amps. per motor armature
Continuous Rating 550 amps. per motor
24th M.H. notch curves are cut off at 2:1 Ratio of A.A./A.F.

Fig. 4. Characteristic braking curves of the 1 — C + C — 1 10,500-volt 25-cycle locomotive

and 4 give, respectively, the motoring and braking characteristics of this locomotive.

Of the 1 — D + D — 1 locomotives 2 were placed in the Skykomish-Cascade tunnel service in March 1927, 2 in the fall of 1928, and 1 early in 1929. The 5 locomotives of this class thus have been in service for the equivalent of about 23 locomotive years. Two of the 1 — C + C — 1 locomotives were placed in the Skykomish-Cascade tunnel service in September 1927, 2 others a year later and 4 were ordered in October 1929, 9 months after the complete electrification had been placed in operation. These locomotives now have been in service about 2 years so that the 8 units of this class have been in service the equivalent of 25 locomotive years.

Of this grand total of 48 locomotive years, approximately 9 years were in the service between Skykomish and Cascade Tunnel as originally planned. This service consisted of helping the regular steam locomotive up the 2.2 per cent grade to the entrance of the tunnel, through which the grade was reduced to 1.695 per cent, making it possible to shut off the steam while in the tunnel.

During 1927–1928, freight trains, ranging from 2,500 to 3,500 tons trailing, were brought to Skykomish by 2 steam locomotives. There, the rear steam locomotive was dropped off and replaced by 2 electric locomotives, one ahead of the steam road engine and one in the rear of the train. In the beginning, the rear locomotive was put at the extreme ends of the trains, but later it was found to be safer to place the rear unit about half to two-thirds back in the length of the train to prevent possible buckling of the train at some weak spot. These heavy freight trains were taken from Skykomish to Cascade tunnel, 25 miles, in $1^3/_4$ hours whereas with steam operation from 4 to 5 hours usually were required. On passenger trains, one electric locomotive was placed ahead of the steam locomotive to help propel the train, in accordance with requirements, to the entrance of the tunnel through which the electric locomotive hauled the train and engine unaided. This operation was begun in March 1927 and continued until the opening of the new tunnel January 12, 1929.

Wenatchee being a division point, all engines and crews of both passenger and freight trains are changed on arrival there. On arrival of all trains at Skykomish from the west, the engine crews shift from the steam locomotives to the electric and continue the trip to Wenatchee; all westbound engine crews similarly transfer from the electric to the steam locomotives and continue to Seattle.

## Early Operating Troubles in New Tunnel

The first 10 days of electrical operation over the new route through the new tunnel was without serious incident. On 2 occasions before the opening of the tunnel, there had been instances of arcing to ground from terminals of current transformers while locomotives were standing inside the new tunnel near the east portal. However, no serious damage resulted.

On one occasion in the old tunnel a transformer had been lost and an arcover at current transformer terminals on 2 locomotives had occurred in zero weather during the first winter after electrical operation began there. A frequency changer set used in connection with the work on the new tunnel had burned out and other disturbances on the line had occurred on the same day, so it was thought these troubles were due to surges. Additional insulation was installed on the terminals and transformers where the trouble seemed to have originated and no further trouble occurred. Therefore when arcovers began to occur in the new tunnel, steps were taken immediately to have 3 surge recorders placed on the trolley circuit, one at each end of the tunnel and one midway between. A fourth recorder was placed on a locomotive running over the entire line. These had just been installed when sub-zero weather arrived and more serious troubles began.

Within less than a week 4 locomotive transformers burned out and several arcovers occurred from terminals of current transformers to ground. In every instance, these troubles occurred on a locomotive attached to a freight train westbound through the tunnel. No trouble was experienced on locomotives hauling passenger trains nor on locomotives eastbound hauling freight trains. The loss of 4 out of a total of 14 main transformers within a week was alarming and even seriously threatened the possibility of continuing to handle all of the traffic over the line electrically.

The surge recorders were left on the circuit from 3 to 4 weeks, during which time there were arcovers and burnouts of transformers. A careful examination of all the records, however, failed to indicate that there had been any surges registered higher than about 2 times normal voltage. This being well within the limits ordinarily expected from necessary switching operations, surges were eliminated from responsibility for the trouble.

## TROUBLES DUE TO CONDENSATION

When the temperature outside the tunnel was below freezing, some signs of condensation had been noted on the outside of the locomotive cab and on the inside near the air intakes. This condensation increased as the temperature outside approached zero. The east end of the new tunnel is at about 634 ft greater elevation than the west end and this, together with the piston action of the moving trains, afforded satisfactory ventilation ordinarily, but it was found that the temperature of the air in the tunnel near the middle varied only between 50 and 65 deg F irrespective of the outside temperature (see Fig. 5). Since the draft was toward the east portal, the rise in temperature entering the tunnel from that end was much more rapid than from the west end. To add to the difficulties, the outside temperature on the east side of the mountain usually was lower than on the west side.

A locomotive starting from Wenatchee with normal ventilation, when the outside temperature was below zero, would show little rise in temperature by the time it had reached the east portal of the tunnel so that immediately after entering the tunnel and encountering the much warmer air, frost began to collect on the outside of the cab and truck; within 2 or 3 minutes, the locomotive was coated thickly with frost crystals, the accumulation of which continued until the locomotive began to warm up when this frost would become liquid and begin to drop off. The same action took place inside the locomotive but to a lesser extent.

At times, when the moisture precipitation was greatest, corona was observed on the 11-kv circuit, particularly at taped joints and terminals. It was no doubt the corona at the surface of the heavily taped terminals connecting the current transformers on the 11-kv circuit to the primary of the locomotive transformer that caused the arcovers to ground at this point.

The moisture condition was aggravated by the large volume of air drawn into the locomotive by the blowers for cooling the electrical equipment. The outside temperature east of the tunnel varies from around 100 deg F in summer to 15 deg below zero during winter, making it necessary to supply as much as 40,000 cu ft of air per minute during the hottest weather.

Experiences with other locomotives requiring much less ventilating air had indicated conclusively that during rain or snow storms dangerous quantities of moisture would be carried inside the locomotives by this large volume of air. To protect the electrical equipment from this danger the louvers for the 1 — C — C — 1 locomotives had been provided at the factory with adjustable shutters by means of which the openings for air intake could be varied from fully open to fully closed. In order to insure proper ventilation of the apparatus when the louvers were closed, dampers were placed in the outlets for the air from the apparatus to direct the air back into the locomotive for recirculation through the apparatus, thus replacing the moisture-bearing air from the outside.

## TROUBLE CURED BY CLOSING VENTILATING LOUVERS

While it had not been foreseen that there would be so great a variation between the temperature outside and inside the tunnel as to cause serious trouble, these provisions for closing the louvers and recirculating the inside air were readily applicable to overcoming this unexpected danger. By closing the louvers and adjusting the dampers at the beginning of a trip the air inside the locomotive was raised easily to a temperature so nearly approaching that of the air inside the tunnel as to prevent any harmful precipitation of moisture. When weather conditions are such as to require the closing of the louvers the temperature outside is never at a maximum so that recirculation of the inside air does not cause excessive heating of the apparatus.

Since operation with closed louvers was begun, the electric locomotives have operated through 3 winters without any trouble from condensation. Moreover, this trouble from condensation is the only serious difficulty that has been experienced in the operation of the electrified line.

## COST DATA AND COMPARISONS

Motor-generator locomotives are well adapted to service where the freight trains may vary from 2,500

**Table II—Comparison Between the 2 Types of Motor-Generator Locomotives in Use**

to 5,000 tons trailing and where it is desirable to limit the maximum power demand to the most economical point. However, the first cost of this locomotive and its weight per horsepower is apt to be greater and its over-all efficiency somewhat less than of other types. The maintenance cost of these locomotives during the 3 years 1928-30 has been 28.66 cents per locomotive mile, or 13.65 cents per 100 tons on drivers. A comparison of these costs with those of 3 other electrified roads using locomotives in similar service with regenerative braking on heavy grades is as follows:

| | Locomotive Miles | Per Locomotive Mile | Per 100 Tons on Drivers |
|---|---|---|---|
| Chicago, Milwaukee, St. P. & P. | 7,939,539 | 14.20c | 6.92c |
| Norfolk & Western | 1,520,608 | 46.82 | 17.60 |
| Virginian | 1,562,574 | 48.49 | 12.26 |
| Great Northern | 937,492 | 28.66 | 13.65 |

A direct comparison of operating expenses between steam and electric operation is impossible for the reason that the route now being operated electrically never has been operated by steam. Furthermore, the shortening of the route and the reduction of elevation by the new tunnel have had important parts in reducing the operating expenses.

However, early in 1920, a study of the old line was made with a view to electrification. In this study operating data and costs were carefully prepared covering 12 months ending September 30, 1919 for steam operation between Skykomish and Wenatchee through the old tunnel. These data are still available for comparison with corresponding costs covering the year 1929, with electrical operation over the new line. Table III shows a comparison of those items of operating expense vitally affected by electrical operation for the 2 years mentioned.

## Table III—Comparison of Steam and Electric Operating Costs

| | Steam | Electric | Difference Amount | Difference % of Steam |
|---|---|---|---|---|
| Route miles | 80 | 73 | 7 | 8.8 |
| Locomotive miles | 767,151 | 406,910 | 360,241 | 47.0 |

| Substations | 5,543 | 5,995 | +452 | 8.2 |
| Distribution | 3,411 | 41,917 | +38,506 | 1128.9 |
| Total | $1,439,641 | $613,810 | $825,831 | 57.3 |
| Avg. cost per 1,000 ton miles | 2.968 | 1.504 | 1.464 | 49.3 |
| Avg. cost per train mile | 2.372 | 2.095 | 0.277 | 11.7 |
| Avg. tons per train, freight | 1,882 | 3,021 | 1,139 | 60.5 |
| Avg. tons per train, passenger | 494 | 568 | 74 | 15.0 |
| Avg. road time, freight | 13.4 | 5.5 | 7.9 | 59.0 |
| Avg. road time, passenger | 4.1 | 2.8 | 1.3 | 31.7 |
| Avg. mph, freight | 6.0 | 12.9 | 6.9 | 115.0 |
| Avg. mph, passenger | 19.4 | 25.5 | 6.1 | 31.4 |

PROPORTIONED BETWEEN FREIGHT AND PASSENGER SERVICE

| | Steam Freight | Steam Passenger | Electric Freight | Electric Passenger |
|---|---|---|---|---|
| Locomotive miles | 466,428 | 300,723 | 199,806 | 207,104 |
| Train miles | 207,286 | 399,720 | 98,478 | 194,452 |
| 1,000 ton miles | 390,000 | 95,000 | 297,550 | 110,558 |
| Total cost, items affected | $1,067,641 | $372,000 | $391,810 | $222,000 |

The total cost of the improvements involved in building the new line and the electrification was, in round numbers, $25,500,000 made up as follows:

| | |
|---|---|
| 7.79 miles tunnel complete | $14,000,000 |
| 17.0 miles new track | 5,000,000 |
| 73 miles electrification | 6,500,000 |

Segregated costs of the electrification were approximately as shown in Table IV.

In reviewing the study made in 1920 relative to the electrification of the old line for comparison with the present electrification, it was interesting to find an estimate of the cost of the proposed electrification of 80 miles of line between Leavenworth and Gold Bar through the old tunnel and which would require the same electrical equipment as the present electrification. The estimated cost of the complete electrification at that time was $6,463,750, or $80,800 per route mile; of this amount, $3,250,000 or 50.28 per cent, was for electric locomotives. Savings from electrical operation estimated for items affected were $639,703.

## Table IV—Itemized Cost of the Skykomish-Wenatchee Electrification*

| | Amount | Per Route Mile | Per Cent of Total: Less Locomotives | Per Cent of Total: With Locomotives |
|---|---|---|---|---|
| Substations, etc. | $1,062,611 | $14,556 | 33.63 | 16.21 |
| Transmission system | 531,967 | 7,287 | 16.70 | 8.12 |
| Power distribution | 368,040 | 5,042 | 11.56 | 5.62 |
| Poles and fixtures | 567,265 | 7,771 | 17.81 | 8.66 |
| Telephone and telegraph changes | 157,440 | 2,157 | 4.94 | 2.40 |
| Signals and interlocks | 155,970 | 2,136 | 4.90 | 2.38 |
| Shops, machinery, tools | 138,357 | 1,895 | 4.34 | 2.11 |
| Engineering | 203,512 | 2,788 | 6.39 | 3.10 |
| Total less locomotives | $3,185,162 | $43,632 | 100.00 | 48.60 |
| Locomotives | $3,368,338 | $46,141 | | 51.40 |
| Total | $6,553,500 | $89,773 | | 100.00 |

* $174,604 credit deducted for 14 miles of electrified line abandoned. Route miles 73; track miles 91.

While a large portion of the savings shown in Table III favorable to electrical operation is due to the new tunnel, this improvement would not have been practical without electrical operation. The decision to build the tunnel was reached only after a careful report had been prepared which indicated that interest on the capital charge would be covered easily by the saving in like charges for new snow shed construction and in maintenance charges for these sheds in the future, thus putting the investment for the new tunnel on a self-supporting basis.

Saving in operating expense shown in Table III is equal to 12.63 per cent on the gross cost of the electrification which, together with the shortened time and other improvements in the service, makes the electrification a favorable investment with a normal volume of traffic. The electrical equipment is easily capable of handling an increase of 50 per cent in the freight traffic and with such an increase, the saving in operating expenses would be in about the same proportion, making the return on the gross investment for electrification approximately 18 per cent.

Capacity of this portion of the line which, with a congestion of traffic, undoubtedly would become the bottle neck of the system with steam operation has been increased 100 per cent as is indicated by the records. These records show that whereas with steam operation in 1920, 3 steam locomotives averaged approximately 6 hours to take a 2,250-ton train the 24.3 miles from Skykomish to the old summit, in 1929 2 electric locomotives averaged about $1^1/_2$ hours to take a 5,000-ton train the 21.2 miles from Skykomish to the new summit. In ton miles per train hour, this is 70,666 for the electric as against 9,112 for steam, a ratio of 7.7 to 1 in favor of electrical operation.

# Distribution System Lightning Protection;

## Interconnection of Primary Arrester Ground and Secondary Neutral

**Although distribution transformers have high impulse strength compared to their normal voltage ratings, they still flash over and fail in service even when protected by arresters. Interconnecting the ground lead of the primary arrester with the transformer secondary neutral limits the voltage across the transformer insulation to that permitted by the arrester alone, and introduces no additional hazard on the low voltage circuit where secondary neutral ground resistances are low. This is the first group of articles dealing with the subject of protecting distribution systems from lightning; articles dealing with other phases of the problem will appear subsequently in ELECTRICAL ENGINEERING.**

LIGHTNING SURGES in ordinary urban distribution circuits manifest themselves in a manner somewhat different from that of those occurring on high voltage transmission lines. In the distribution circuit the arrester spacing usually is such that the distance traveled by the voltage wave will be short, the crest voltage appearing on the line will be limited, and the surge will manifest itself as current through one or more arresters. The current wave, both as regards magnitude and shape, is determined largely by the lightning stroke and but little by the characteristics of the distribution circuits. On rural lines the exposure between arresters is much greater, so that in addition to surges originating near the arrester there are surges arriving over a length of line. Crest voltages of these surges are limited by the line insulation.

Experience has shown that although failures of distribution transformers and the blowing of fuses during lightning storms are reduced greatly by the application of lightning arresters, the record of protection is not so good as the strength of the transformer and performance data of the arrester would indicate it should be. In general, the ratio between the strength of the transformer insulation and the voltage allowed by the arrester is not far from 4 to 1. With such a large margin, failures of transformers or fuse blowing due to lightning should be practically eliminated except in the case of a direct stroke at the transformer location, a relatively infrequent source of trouble.

Protection now commonly employed for distribution transformers provides for phase and neutral arresters on the primary side of the transformer. With few exceptions these arresters are connected to a common ground lead which in turn is connected to a driven ground rod at the base of the pole. This arrangement is based upon the supposition that lightning surges entering over the primary conductors would pass to ground, and that the arrester would hold the primary winding to a potential equal to the arrester discharge voltage. Unhappily, this condition does not hold in practice because arrester ground resistances are not zero, but may be as high as several hundred ohms. Furthermore, the exposure of secondary circuits in urban districts may exceed by far the exposure of primary circuits there; hence lightning surges frequently enter on the secondary conductors when primary arresters connected in accordance with present practise are not in position to be of service.

From the foregoing it is clear that several factors may prevent the primary arresters from properly protecting the distribution circuits. Connecting the arrester ground to the grounded secondary neutral, however, appears to eliminate many of the disturbing factors. With such a connection the voltage between the transformer windings under impulse conditions will not exceed the potential allowed by the arrester; this potential is low enough for transformer failures from bushing flashovers to be practically eliminated. With this idea in mind several investigations have been conducted in various parts of the country; 3 of these are covered in the following 3 articles. The first, by Opsahl, Brooks, and Southgate, includes a theoretical study and laboratory tests made to determine the effectiveness of interconnecting in different ways the primary arrester ground and the secondary neutral. The second article, by Harding and Sprague, covers tests made on an experimental line built in accordance with standard construction practise of the Commonwealth Edison Company of Chicago. The third article, by McEachron and Saxon, describes tests made on an actual distribution line built to serve a small rural community in central New York.

From the investigations conducted, the information presented in these articles indicates that much greater protection to distribution transformers is effected through interconnecting the primary arrester ground with the grounded secondary neutral than through present protection schemes. Further, it is shown that this interconnection introduces no additional hazard in the low voltage circuit except where the secondary neutral ground resistance is high.

TESTS show that when a surge is applied to the primary of a distribution transformer that has a secondary ground, the isolated case will assume a low electrostatic potential above ground so that about from 80 to 95 per cent of the surge voltage will appear from primary lead to case. For simplicity in the considerations that follow, it will be assumed that the case potential under these conditions is the same as that of the secondary neutral.

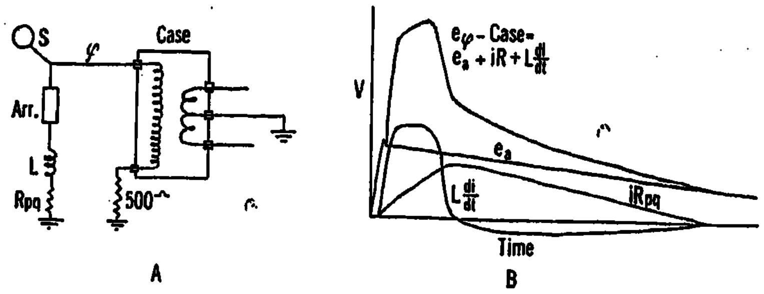

Fig. 1. Lightning surge voltage across the bushings of a distribution transformer protected in accordance with present practise

Potential across a transformer when a surge is applied, as shown in Fig. 1, is the total of 3 components: the *IR* drop across the ground, the inductive drop across the ground lead, and the voltage across the arrester. The *IR* drop across the ground is proportional to the current in the surge, while the drop across the lead is proportional to the rate of rise of current. For anticipated surge currents the voltage across the ground alone can exceed the voltage across the arrester, unless the ground resistance is very low.

With present methods of installation, voltages appearing across the primary bushings often are great enough to cause flashovers; the completed path for the surge current to ground usually is over the secondary bushings. The usual sequence of events during a flashover and the voltages which occur are shown in Fig. 2. Primary bushing flashover takes place at a time $t_1$, and secondary bushing flashover almost simultaneously at a time $t_2$. If the transformer be connected to the power circuit the flashover path will carry the power arc until the primary fuse opens the circuit. In service this is the path over which the arc burns usually are found. Under these conditions both the surge current and the power follow current flow through the secondary neutral ground, but operating experience indicates no serious trouble on the customer's property.

## INTERCONNECTION OF PRIMARY ARRESTER GROUND AND SECONDARY NEUTRAL

By interconnecting at the transformer the arrester ground and the transformer secondary neutral, the potential difference across the primary bushings of the transformer will be limited to the voltage permitted by the arrester alone during a discharge, in accordance with the prior assumption that the secondary neutral and case remain at the same potential. In Fig. 3 is shown the effect of this interconnection where the assumed secondary neutral impedance to ground is small. Whether this secondary impedance be low or high, the potential across the primary bushing will not be greater than that permitted by the arrester alone. Under these conditions the transformer will not flash over and there will be no power current flowing from the primary circuit into the secondary neutral. Whatever impedance drop there is from the surge current flowing in the secondary neutral of course will appear as voltage in that circuit.

If a solid connection is not permissible between the secondary neutral and the ground terminal of the primary arrester, a gap or valve arrester of low voltage rating may be placed in the interconnection

---

Based upon "Lightning Protection for Distribution Transformers" (No. 32-18) presented at the A.I.E.E. winter convention, New York, N. Y., Jan. 25-29, 1932.

as shown in Fig. 4A. This arrester will begin passing current when the voltage across the ground lead becomes great enough to discharge the arrester. In this case the voltage across the primary bushing is the sum of the voltages appearing across the primary and interconnecting arresters as shown in Fig. 4B. This connection will isolate effectively the arrester ground and the secondary neutral, as there is no potential difference between them except during a surge discharge.

A second method of obtaining the improved protection afforded by the interconnection without connecting a solid conductor between the arrester ground and the secondary neutral, is that shown in Fig. 5. Where the effective leakage reactance between the 2 halves of the secondary winding is small, the surge current in flowing as indicated will result in a low voltage across the winding as the magnetic effects of the 2 currents are in opposition.

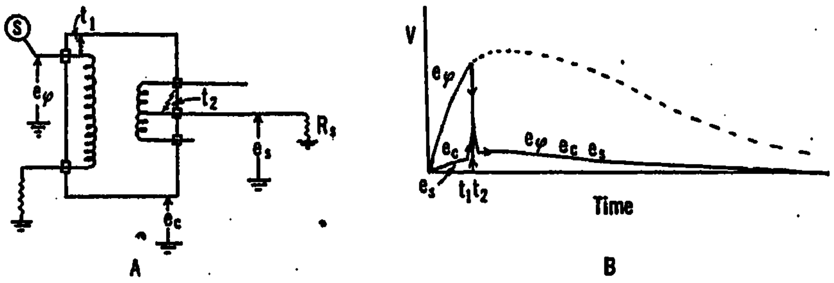

**Fig. 2. Voltage-time relation as a flashover occurs on a distribution transformer from a surge applied to the primary**

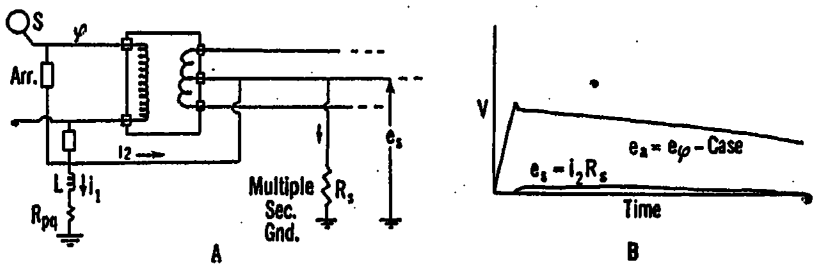

**Fig. 3. Voltage across transformer bushings with primary arrester ground lead interconnected to secondary neutral; surge applied to primary**

This circuit was proposed by C. B. Wright of the Duquesne Light Company (Pittsburgh, Pa.) and has shown very promising results in laboratory tests.

At present the safety code in most localities forbids the interconnection of the primary arrester and the secondary neutral grounds. This regulation was made in recognition of the fact that when a surge current flows through a ground a surge voltage appears across it. The driven grounds which were assumed when the regulation was adopted usually have a much higher resistance than the water pipe grounds ordinarily used at the present time.

### Limitations of the Interconnection

Where both primary arrester and secondary neutral grounds are driven grounds, as in the case of a rural customer, the interconnection can prevent flashover across the transformer insulation, but an appreciable surge voltage may appear from secondary to ground. This condition is less serious than permitting a power fault in the secondary circuit, but the resistance of both grounds should be made as low as possible so that the surge $IR$ drop may be low.

The ungrounded secondary is not common practise in distribution circuits; where it is used, a surge on the transformer primary will give the secondary circuit a potential above ground and the smaller the capacity of the secondary to ground, the greater will be its potential. Obviously an interconnection of a poor primary ground with the free secondary will not lower the voltage across the arrester ground appreciably, and flashovers from secondary to ground would be expected.

### Tests on a Typical Distribution Circuit

To determine the magnitude of the effects required to cause flashovers similar to those that have occurred in service, a program of tests was carried through. A diagram of the test circuit is shown in Fig. 6. The distribution transformer shown was mounted on a 35-ft pole. A ground lead was provided down the pole and in order to obtain low ground resistance, 2 ground rods were driven at the foot of the pole. The secondary wires were racked for about 140 ft. From the transformer pole and from the end of the secondary rack triplex services were run to a point on the ground where the neutral wires were solidly grounded. One wire of each triplex service was left open, as indicated in Fig. 6 by "open service." One service wire and the neutral from each service were connected to a 100-ft section of 2-conductor metal-armored BX cable, both ends of the armor being grounded. The 2 sections of BX cable were connected to the same 2 secondary wires.

In the tests as made, flashovers were necessary in order to simulate conditions that obtain in practise.

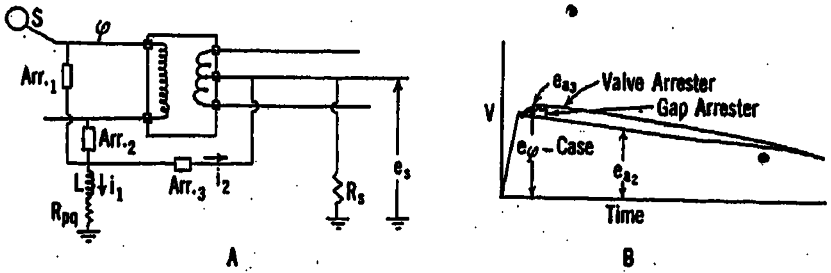

**Fig. 4. Surge voltages across transformer bushings with primary arrester ground connected to secondary neutral through low voltage arrester; surge applied to primary**

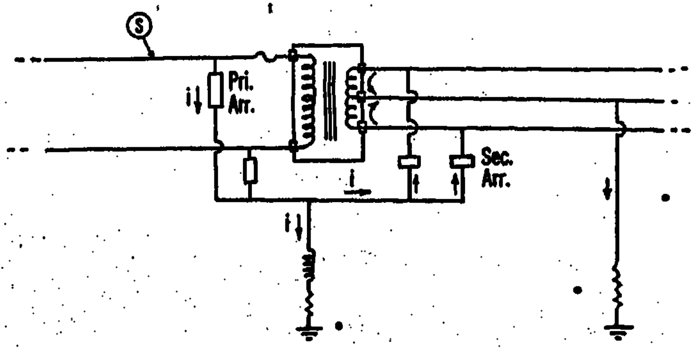

**Fig. 5. Primary arrester ground connected to transformer secondary leads through secondary arresters; surge applied to primary**

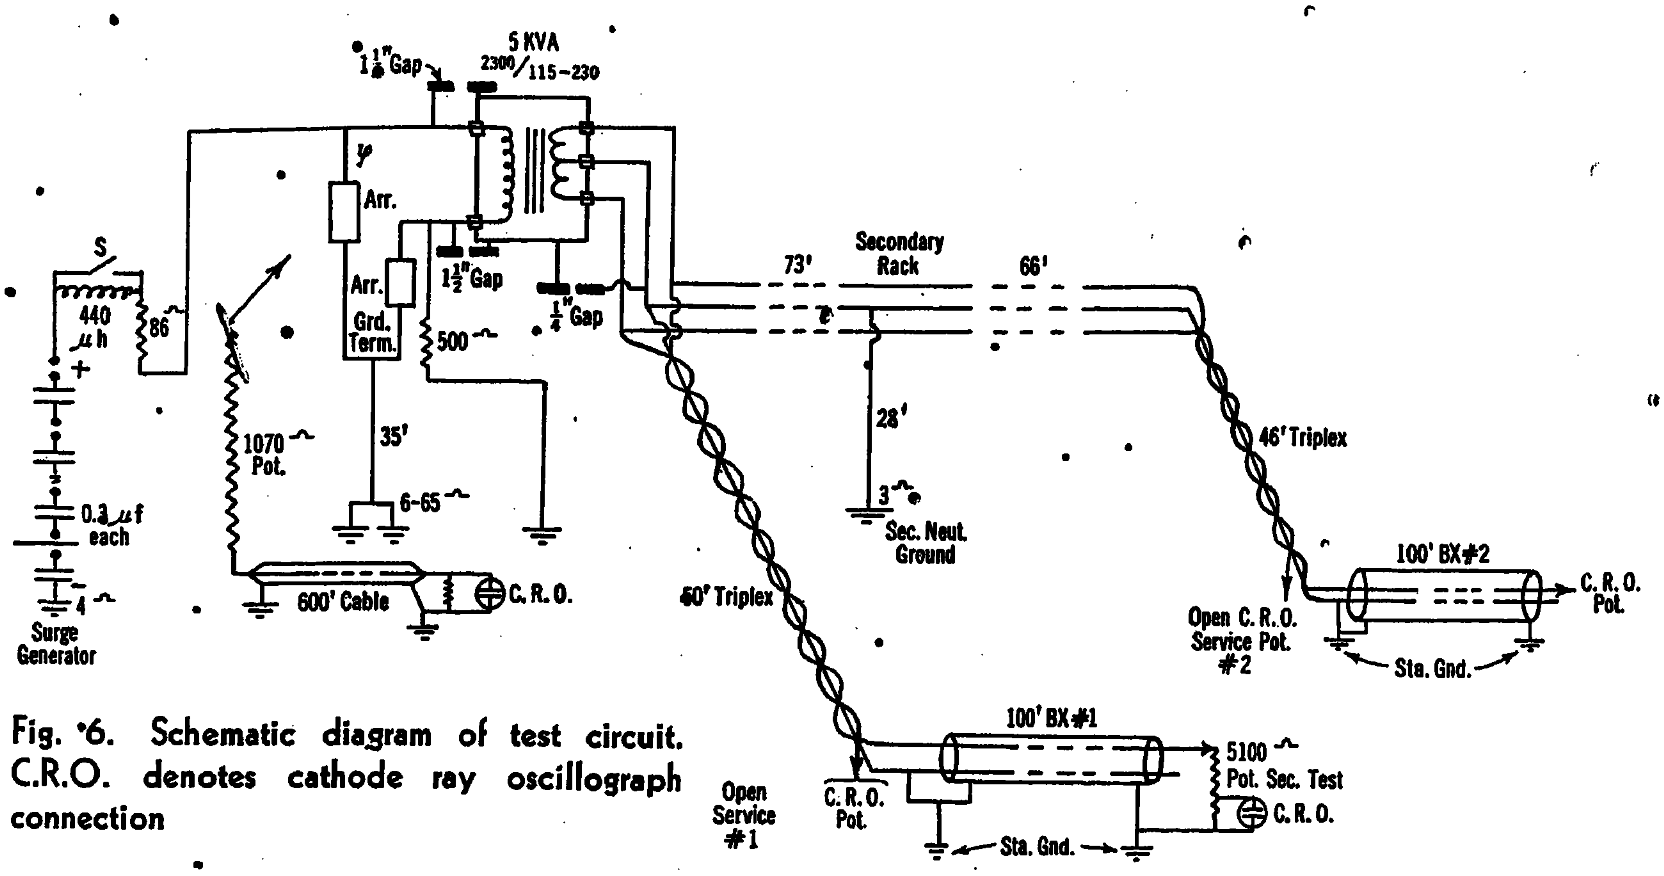

Fig. 6. Schematic diagram of test circuit. C.R.O. denotes cathode ray oscillograph connection

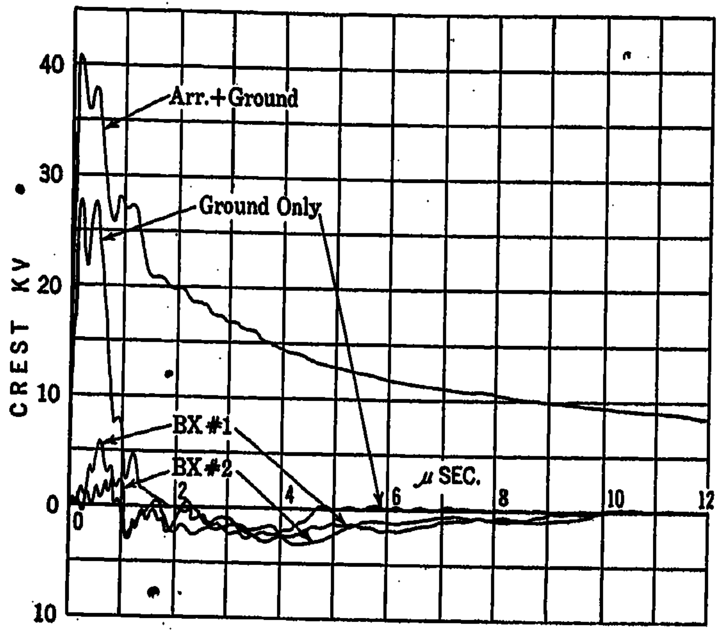

Fig. 7. Voltages measured in circuit of Fig. 6 with steep front surge of reduced magnitude

The gaps may have flashed accidentally during the oscillographic measurement of the voltage across the arrester lead plus ground, since the lack of sustained voltage seems incompatible with the given values of current and ground resistance, and also because the difference between the arrester-plus-ground and the arrester-lead-plus-ground voltages is greater than the arrester voltage, 15 kv. This curve is almost identical with the corresponding curve in Fig. 9

To secure consistent flashovers, gaps were placed around the primary and secondary bushings as shown in Fig. 21. A 500-ohm resistor was connected between the primary neutral and ground to simulate the effect of an uncharged conductor.

Arresters used in these tests were 3-kv autovalve arresters of the disk and mica spacer type. This type of arrester was selected rather than the porous block type because many of them are in service and because the tests were laid out to duplicate service conditions as closely as possible. Upon test, this type of arrester was found to have a maximum crest voltage of 15 kv across its terminals during a surge discharge of 800 amp.

Most of the oscillograms have been replotted to the same scale to show more readily the relative voltage-time values; a few of these are shown in Figs. 7 to 12, inclusive. Crest voltages measured at certain points for the various circuit connections and for each of the 2 types of impulse wave used are given in Table I.

Voltages at the transformer were measured by means of a cathode ray oscillograph connected to a 1,070-ohm resistance potentiometer through a delay cable. Voltages at the secondary service terminals were measured by a 5,100-ohm resistance potentiometer. These potentiometers of course have some effect on the surge voltages.

## Effect of the Ground Lead on Protection

To show the effect of the inductance of the arrester ground lead on the voltage appearing across the primary bushing, 2 rates of current rise were selected. The "slow" rate of current rise was produced by introducing the 400-microhenry inductance into the circuit of the surge generator (Fig. 6). The steep front surge rose to a maximum of 1,200 amp in 2 microseconds, while the slow front surge rose to 900 amp in 9 microseconds. Successive test surges were found to be practically identical.

With the surge generator set to give a current wave of fast front and a crest of slightly less than 1,200 amp in order to prevent flashover of the transformer gaps, the oscillograms shown in Fig. 7 were taken. In Fig. 8 are plotted oscillograms obtained using the slow front surge with no gap flashovers and with standard connections. Crest voltages for these tests are listed in Table I. These tests indicate that after an initial disturbance determined by the surge impedance of the ground lead, the voltage across the ground lead is determined by the lead inductance and the rate of change of current. The initial disturbance is due in part to the type of surge circuit used.

At the 1,200-amp surge generator setting the transformer gaps flashed over at 50 kv from line to ground; in Fig. 9 are plotted voltage oscillograms so obtained. As before, the crest voltages are listed in Table I. The voltage across open service No. 2 was 33 kv compared to 24 kv across BX No. 2, showing the attenuating effect of the BX cable on the surge.

### Tests With Arrester Ground and Secondary Neutral Interconnected

In Fig. 10 are plotted oscillograms taken when the arrester ground terminal and secondary neutral were interconnected. No gap flashovers took place. As may be seen, the difference in potential between the phase lead and the secondary neutral does not exceed 15 kv, the voltage permitted by the arrester alone. A comparison of columns 3 and 4 of Table I indicates that the crest secondary voltages are about the same with the interconnection as they are during a flashover of the transformer gaps without the interconnection.

The extreme case of high arrester ground resistance is that of no ground at all. Obviously with no ground the arrester could not discharge and any surge above 50-kv crest would flash over the transformer gaps. Under such conditions, protection for the transformer can be obtained by connecting the arrester ground terminal to the secondary neu-

* All voltage measurements were made by resistance potentiometers and cathode ray oscillographs.

tral. To investigate this the circuit of Fig. 6 was modified by connecting the ground terminals of the primary arresters to the secondary neutral only. Under such conditions the full surge current flows to ground through the transformer secondary neutral wire. Figs. 11 and 12, respectively, show the voltages measured with steep front and slow front surges. In neither case did the transformer gaps flash over, as the voltage across the transformer bushings was limited by the arrester to about 15 kv. The maximum voltage to ground with the fast surge was 60 kv, which was considerably above the gap flashover voltage.

A test was made to investigate the effects of the indirect interconnection of the secondary neutral and arrester ground, using the circuit shown in Fig. 5 except that the separate arrester ground was omitted so that the only path for the arrester surge current was through the secondary arresters, secondary windings, and secondary neutral to ground. Crest voltages for this test are shown in Table I column 8. A comparison of columns 7 and 8 of Table I shows that the leakage reactance between the 2 secondary windings of this transformer evidently was high enough to increase the voltage appearing across the service wires. This same circuit was tested with the steep-front surge. The voltage was sufficiently great to cause a flashover in the BX cable, so no measurement was made; however, no flashover occurred on the transformer gaps.

### Surge Voltages Appearing on the Secondary

A surge voltage impressed across the primary of a distribution transformer will induce a voltage across the secondary; this voltage has a duration about the same as that of the primary voltage. A rapidly changing surge current passing to ground over the secondary neutral produces an oscillatory voltage between the outside wires and ground at the service terminals, the maximum value of which is about the same as that of the transformer neutral to ground at the transformer. However, the voltage on the BX cable (Fig. 6) is lower than that on the corresponding open service; and the voltage on the more distant service, No. 2, is greater than that on service No. 1.

Voltages appearing at the services when the arrester ground and secondary neutral are interconnected are about the same as those appearing when a steep-front surge causes the transformer gaps to flash over due to the inductive drop in the arrester ground lead.

Secondary voltages with the arrester ground and secondary neutral interconnected, though of short duration, appear to be of rather high magnitude. While the secondary voltages with this circuit may be compared with corresponding voltages on the other circuits tested, it should be noted that the length of racked secondary was short as compared with lengths usually found in practise, and that voltages on an actual distribution system probably will be lower. Voltages of the relative magnitudes tabulated in column 3 of Table I appear now without serious effect for transformer flashovers where the ground resistance is low.

### Conclusions

Tests show that when a transformer is subjected to a lightning surge the case will assume a potential of about 10 per cent of that appearing between the primary leads and secondary neutral. Neglecting the potential of the case the voltage across the transformer bushings is the sum of the voltages across the arrester, the arrester ground lead, and the arrester ground resistance. With a surge of steep front the inductive voltage across the ground lead alone may exceed the arrester voltage. Remedial steps which can be taken are limited to a reduction of the arrester ground resistance and of the inductive drop across the ground lead. Practical application of these measures is limited by field conditions.

Improved protection of a distribution transformer may be secured by any one of several methods of connecting the arrester ground lead to the secondary circuit. The following methods will limit the surge voltage across the bushings to approximately the characteristic crest voltage of the primary arrester, but will differ in resulting secondary voltages:

1. Direct connection of a low resistance primary arrester ground to a grounded secondary neutral produces no higher voltages at the customer's service than are experienced when flashover occurs with present protection schemes.

2. Direct connection of a high resistance primary arrester ground to a grounded secondary neutral results in higher surge voltages appearing on the customer's leads than when the ground resistance is low.

3. Connecting the primary arrester ground to the secondary neutral

through a low voltage arrester gives substantially the same results as the direct connection.

4. Connecting the primary arrester ground to the secondary outside wires through 2 low voltage arresters results in increased surge voltage at the service.

# II—Tests on a Typical Urban Circuit

By
C. FRANCIS HARDING FELLOW A.I.E.E.
C. S. SPRAGUE ASSOCIATE A.I.E.E.

Both of Purdue University, Lafayette, Ind.

UNDER a cooperative arrangement with the Utilities Research Commission of Chicago, the engineering experiment station at Purdue University has been conducting an investigation of surge protection for distribution circuits. Many of the tests have involved the interconnection of the primary lightning arrester ground and the grounded neutral of the secondary main; it is this phase of the work which will be treated in this article.

After some preliminary work, a 5-span distribution line was constructed, over which was supported an insulated artificial cloud for the purpose of inducing surge potentials in the distribution system. The distribution line was of the double-crossarm wood-pole type with 4 4,000-volt primaries on the upper arm and 6 secondaries on the lower arm, the latter comprising a 3-phase, 230-volt power circuit and a single-phase 115/230-volt lighting circuit (see Fig. 15). The line was built in accordance with the standard construction practise of the Commonwealth Edison Company of Chicago. A bank of 3 distribution transformers and a customer's service were included in the distribution system but were not connected to any 60-cycle supply. Circuit grounds were made on the customer's service and on the distribution system as in standard practise. (See Fig. 13 for circuit diagram.)

## POTENTIALS INDUCED ON LINE WIRES

The cloud normally was held at ground potential by means of a high resistance leak. At definite intervals a surge generator was made to discharge into the cloud, thereby causing a sudden change in cloud potential with consequent induced voltages in the distribution system. These induced voltages were measured by a sphere gap at the transformers and at the customer's service entrance.

A series of tests was made in which the induced voltages to ground were measured as the distribution system was built up step-by-step, that is, by starting with the wires only and adding the circuit grounds, arresters, transformer windings, etc., until the system was complete. In Fig. 14 is shown graphically the change in the magnitude of induced voltages during this procedure, and also the system voltages with and without the interconnection of the secondary neutral to the primary arrester ground.

In general, Fig. 14 is self-explanatory, but it is desired to call attention to some of the more interesting changes in the induced voltages and their causes. As noted in the legend, the first vertical line of each group represents the induced voltages on that particular wire with no grounds or connected apparatus. Potentials induced on the primary wires (between wires 1 and 4 and ground) were approximately 90 kv; on the secondary wires (between wires 5, 8, 9, and ground) approximately 75 kv. (See Fig. 15 for positions of wires on crossarms.) In test 2 of each group, wire No. 9 (secondary neutral) was connected to a driven pipe ground of approximately 15 ohms resistance, one span distant from the transformer bank. Aside from the reduction in voltage on wire No. 9, itself, it is interesting to note the reduction on wires 4 and 8, adjacent to wire No. 9.

Test 3 of each group indicates the voltages with the further addition of primary phase and neutral arresters. As would be expected, there was a marked decrease in the potentials of all primary wires. There occurred also a decided reduction in the potentials of the secondary wires (wires 5, 8, 9) due to the shielding effect of the primary wires after the arresters had broken down. This is particularly significant and important for it indicates that in the field a well protected primary system provides considerable protection for secondaries located below the primaries.

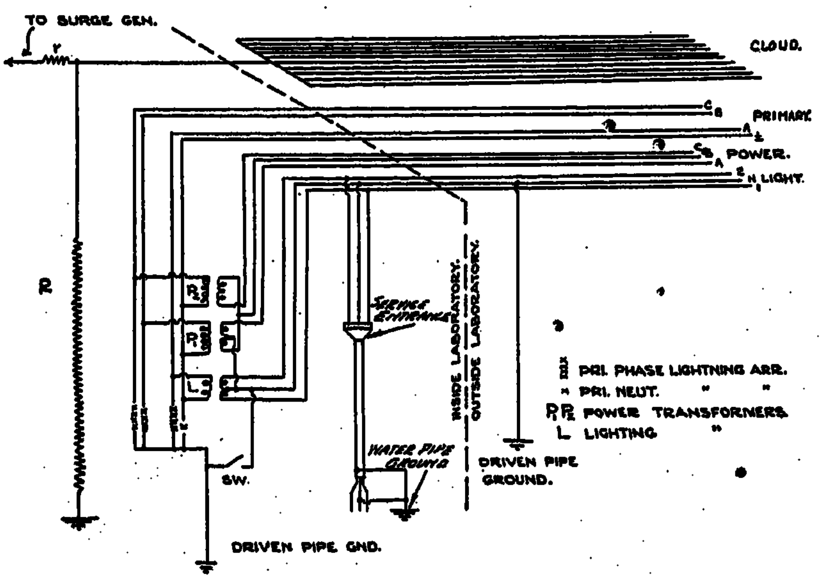

Fig. 13. Circuit diagram of experimental distribution system and artificial cloud

In Test 4, connecting the transformer primary windings caused but slight reduction in induced potentials, showing that the primary winding presents a relatively high impedance to the surge. With transformers, house-wiring circuit, and all grounds connected to the circuit, as in Fig. 13, voltages to

---

Based upon "Interconnection of Primary Lightning Arrester Ground and the Grounded Neutral of the Secondary Main" (No. 32-16) presented at the A.I.E.E. winter convention, New York, N. Y., Jan. 25-29, 1932. Revised especially for ELECTRICAL ENGINEERING and brought up to date.

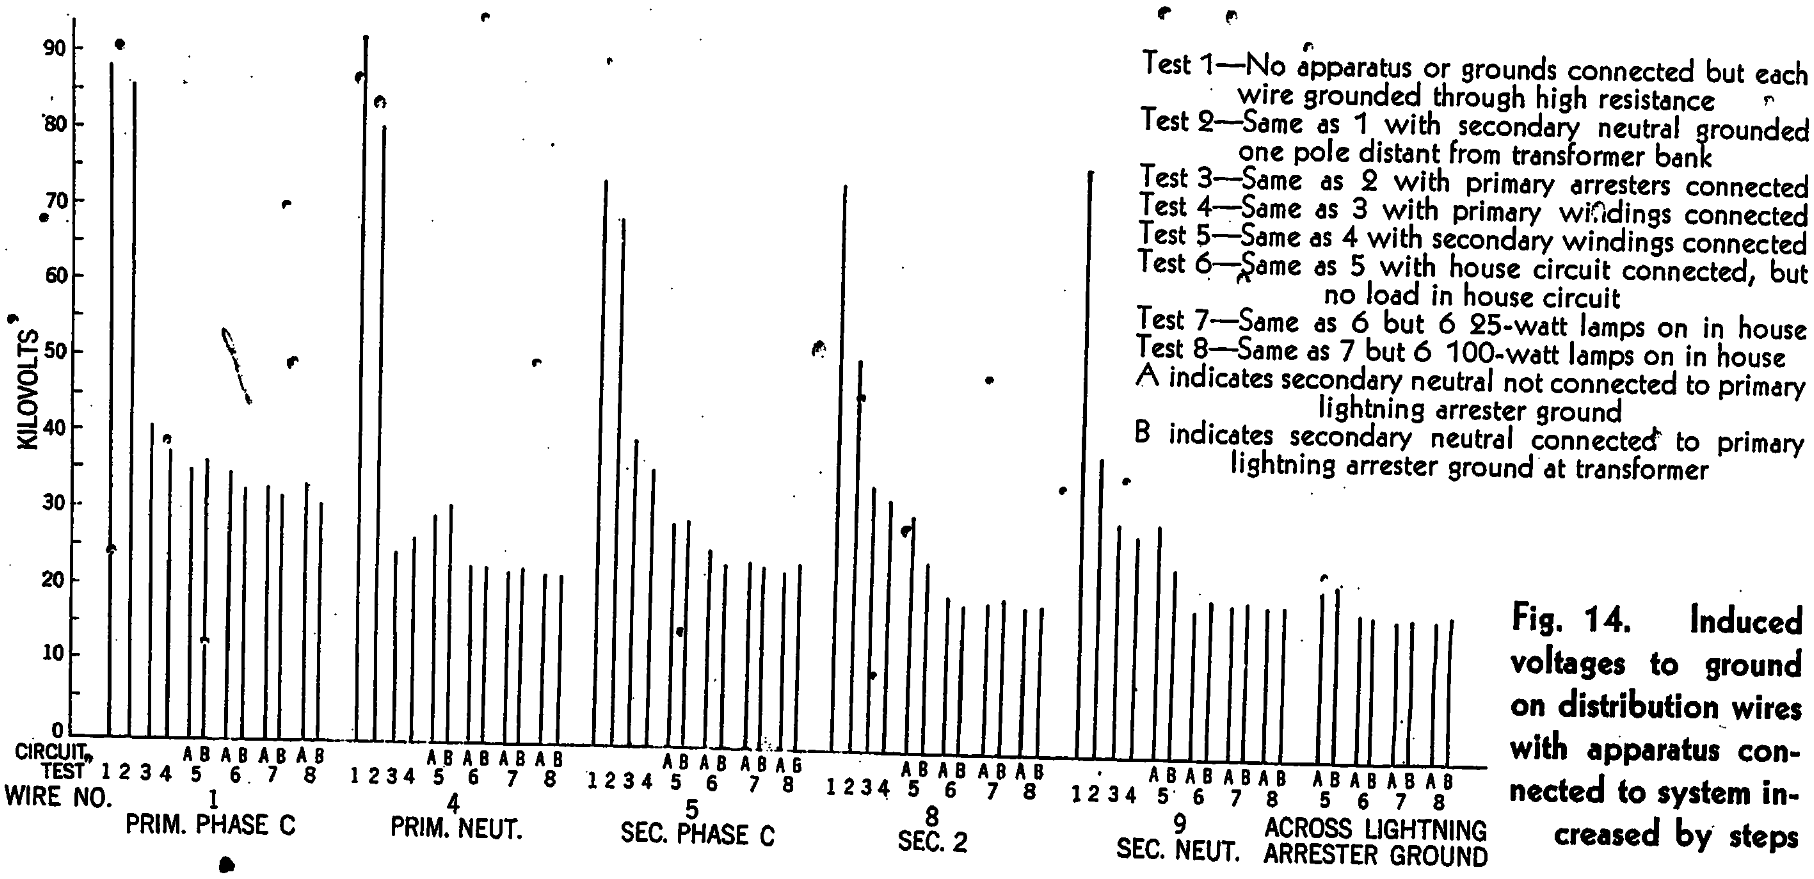

**Fig. 14. Induced voltages to ground on distribution wires with apparatus connected to system increased by steps**

ground on the power and lighting secondaries and on the primary neutral were of the order of 20 to 25 kv while those between the primary phase wires and ground were of the order of 30 to 35 kv.

## POTENTIALS INDUCED IN TRANSFORMER WINDINGS

With regard to voltages across transformer windings it was determined that for a single-phase lighting transformer with its secondary neutral grounded, the voltage across the secondary winding was approximately 5 to 15 per cent of that across the primary winding. With 3-phase 230-volt Δ-connected power secondary windings having the midpoint of one winding grounded to the lighting secondary neutral, it was determined that the voltages across the secondary coils were approximately 20 to 80 per cent of those across the primary windings. In both cases the induced potentials overstress the secondary insulation without exceeding the safe limit on the primary insulation. A solution of this difficulty is of course to increase the insulation of the secondary winding. In so doing, however, capacitances between primary, secondary, and core will be changed; therefore consideration should be given to the redistribution of potentials resulting therefrom. These are relatively inexpensive additions to the design and construction of the transformer.

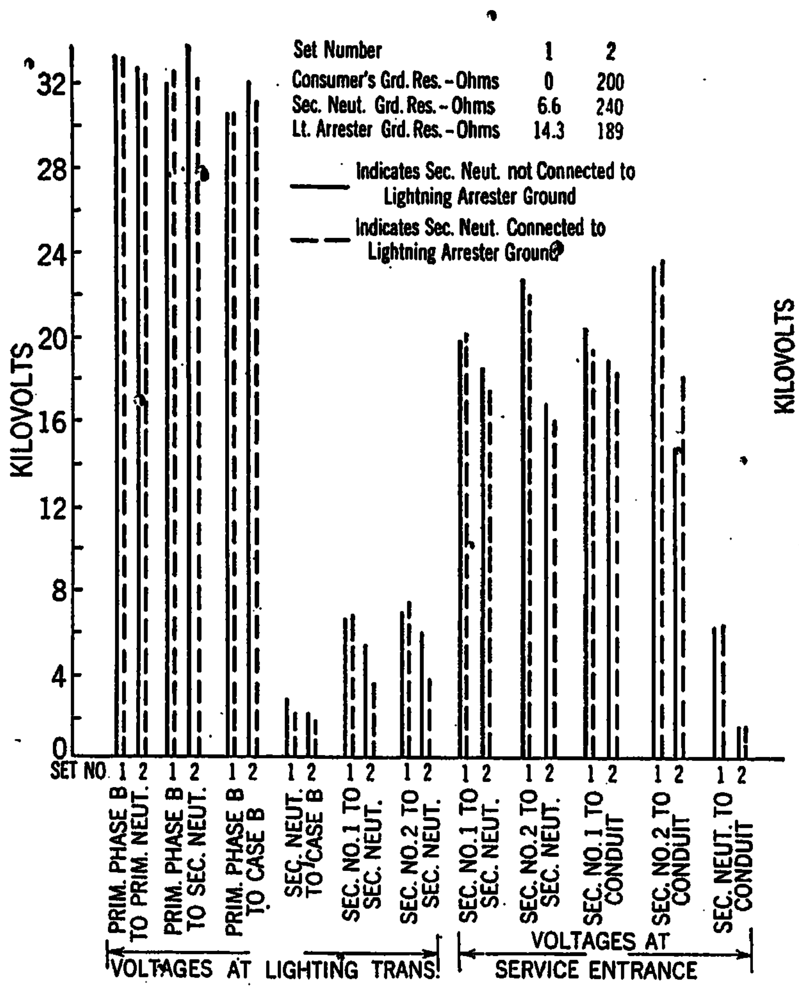
In the preceding group of tests interconnecting the secondary neutral and the lightning arrester ground caused, in general, approximately 5 per cent decrease in magnitude of the induced voltages to ground. The tests indicated, however, that the effect of this connection depends to a large extent upon such factors as the steepness of wave front of the surge, and time lag of the primary arresters; hence, under the test conditions of induced potentials and arrester currents of small magnitudes, it cannot be said that this connection *always* is beneficial.

## TESTS WITH DIFFERENT GROUND RESISTANCES

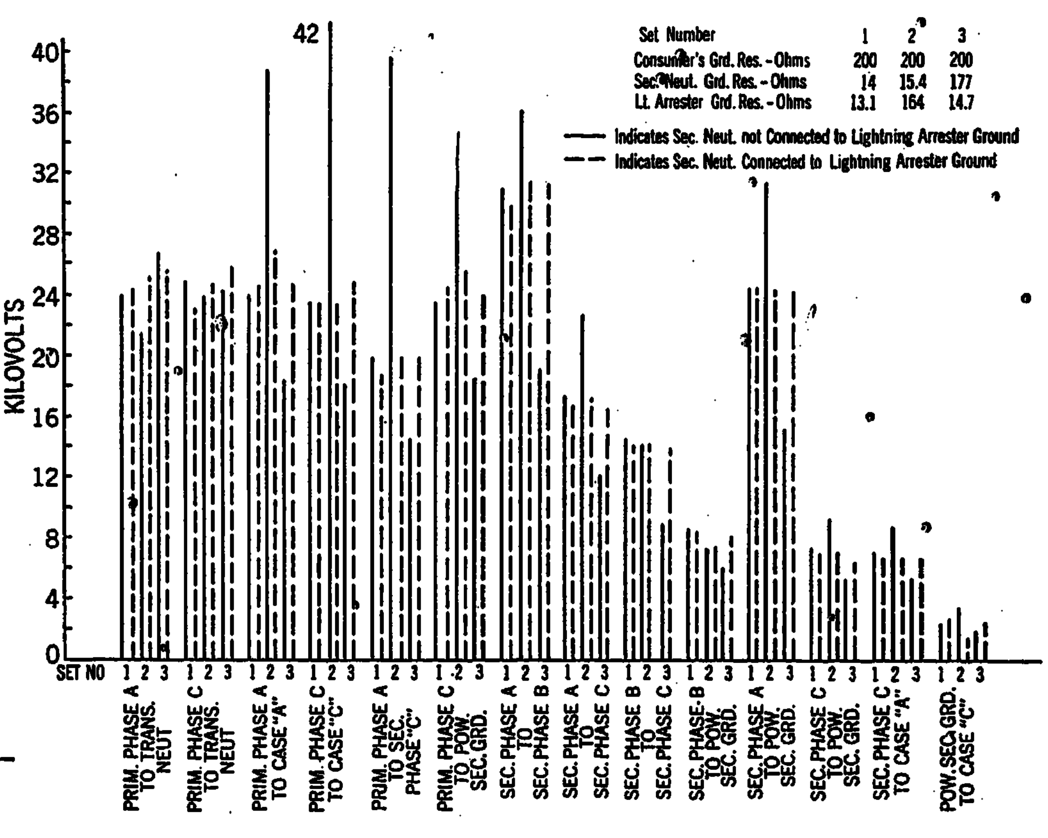
Induced voltages measured at the transformers and at the service entrance under various conditions of ground resistance are shown graphically in Figs. 16 and 17. Tests were made both with and without interconnection of the secondary neutral to the primary lightning arrester ground. In several instances the interconnection caused a marked decrease in the voltage between primary phase wire and secondary ground.

Field investigations have demonstrated that many transformer failures and blown fuses have been caused by flashover from a primary phase lead to the transformer case and thence to the secondary neutral. In fact, operating companies have reported that in about $^3/_4$ of the transformer failures on distribution systems due to lightning, the damage involved both the primary and secondary windings.

Measurements of induced voltages between primary phase lead and secondary neutral have shown that the interconnection of the secondary neutral with the lightning arrester ground in general is beneficial to the transformer. In particular, with a low resistance secondary neutral ground and a high resistance lightning arrester ground, the interconnection reduced this voltage by 30 to 50 per cent. (See Fig. 17, set 2.) With no interconnection and with a high resistance secondary neutral ground and low resistance lightning arrester ground, the voltage between primary phase lead and secondary winding



Secondary neutral ground one span from transformer pole



Secondary neutral ground at transformer pole

**Fig. 16 (left) and 17 (right). Effect of interconnection upon the potentials at the transformers and at the service entrance with various ground resistances**

was somewhat reduced at the expense of an increased voltage across the high resistance secondary neutral ground. By making the interconnection and thereby connecting the low resistance lightning arrester ground in parallel with the high resistance secondary ground, there was a redistribution of voltage so that the potential between primary phase lead and secondary neutral was approximately the same as when using the interconnection and with low secondary neutral ground resistance and high lightning arrester ground resistance. (See Fig. 17, set 3.)

### Potentials at Service

As indicated by Fig. 18, the tests showed that due to making the interconnection there was a 10 per cent reduction in the potentials at the service entrance. There is indicated also a marked reduction in the voltages at the service entrance when the customer's lamps were turned on. This seems to be an argument in favor of turning on the lamps during a thunderstorm.

During the latter part of the work the transformers were mounted on one of the poles and a testing shelter was constructed on poles immediately adjacent to the transformer pole. The induced potentials were slightly higher, but otherwise in good general agreement with those obtained when the transformers were on the laboratory floor. The majority of the tests covered here have been made with the transformers on the poles.

Subsequent to the preparation of the paper presented at the winter convention in New York, tests have been made with the surge generator discharging directly from the cloud into a primary phase wire, giving arrester currents up to 2,000 amp. Under these conditions, the beneficial effect of the interconnection was much more pronounced. Whereas with secondary neutral ground resistances of from 10 to 15 ohms and arrester ground resistances of from 100 to 200 ohms, the transformer bushings repeatedly flashed over, it was found that the interconnection in all cases prevented flashover and reduced the potentials across the transformer to approximately 35 kv.

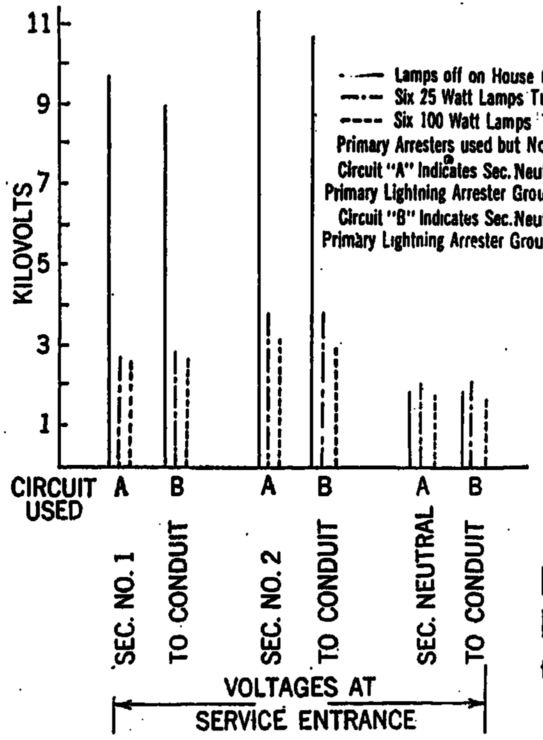


**Fig. 18. Effect of lamp load upon surge potentials at service entrance**

Laboratory surge tests were made on several of the newer surge-proof distribution transformers and also on some rather old and dirt-covered transformers which had seen considerable service. With a lightning arrester operating normally and connected between primary phase and secondary neutral (equivalent to the interconnection) none of the transformers showed any signs of failure.

While in no way depreciating the advantages of the present surge-proof type, this would indicate that increased service and reliability may be obtained from some of the old style transformers if the interconnection is adopted.

Surge tests on the primary bushings of some surge-proof type transformers indicate that well over 100 kv is required to flash over the bushing, due primarily to several layers of cambric tape on the phase lead. In case of possible arrester failure it is evident that the winding insulation may be subjected to abnormally high stress without relief by bushing flashover.

## CONCLUSIONS

From the results obtained in this investigation, the following conclusions seem justified:

1. The value of an experimental wood pole distribution line with an insulated artificial cloud charged by a surge generator was established definitely for lightning protective investigations involving induced as well as direct stroke potentials.
2. The tests demonstrated the practicability and economy of studying, by means of such equipment, the operation of various transformer, lightning arrester, and ground connections, when exposed to surges approximating those of lightning.
3. Efficient primary protection on an overhead distribution line affords considerable protection to secondaries located below the primaries.
4. A well grounded secondary neutral wire reduces potentials on adjacent wires.
5. In existing transformer design the insulation of the secondary winding may be overstressed by steep wave front surges without excessive stress on the primary insulation; such stresses may be relieved by improvements in secondary insulation.
6. Low ground resistances, although desirable in other respects, do not necessarily reduce the initial potentials which may be induced on the system.
7. A non-inductive load in the consumer's premises reduces the potentials 60 to 70 per cent at the service entrance.
8. Interconnecting the primary lightning arrester ground to the grounded neutral of the secondary main greatly reduces the voltages at the transformer and imposes no extra hazard upon the consumer's wiring. Specific cases of this conclusion are covered in the following 4 paragraphs.
9. With the lightning arrester ground resistance and secondary neutral ground resistance below 20 ohms, the interconnection has but little effect upon the magnitudes of induced potentials at the transformer.
10. With an arrester ground of from 100 to 200 ohms and a secondary neutral ground of less than 20 ohms, the interconnection reduces by from 30 to 50 per cent potentials across the transformer terminals.
11. With a lightning arrester ground of less than 20 ohms, and a secondary neutral ground of from 100 to 200 ohms (an unusual combination), the potentials across the transformer terminals were increased about 25 per cent by making the interconnection.
12. With secondary neutral and primary arrester ground resistances both ranging from 100 to 200 ohms, the interconnection had practically no effect upon the magnitudes of the voltages at the transformer.
13. Using "direct strokes" from the surge generator, the interconnection is of great benefit with high arrester ground resistances. With any combination of secondary-neutral and arrester ground resistances, the interconnection limits the transformer stress to the value determined by the arrester voltage, and should reduce materially the lightning failures on non-surge-proof types of transformers.
14. With usual city conditions, consisting of a multiplicity of low resistance grounds on the secondary neutral, and the further possibility in some instances of a lightning arrester ground of high resistance, it has been demonstrated herein that potentials at the transformer may be reduced greatly by the interconnection of the primary lightning arrester ground and the grounded neutral of the secondary main.

NON-MEMBER A.I.E.E. New York, N. Y.

THERE HAS BEEN a growing conviction on the part of those closely associated with the problem of protection that in practise the present method of lightning arrester application on distribution systems involves too many uncontrollable factors. Connecting the primary arrester ground to the grounded secondary neutral appears to eliminate many of the uncontrollable factors. With such a connection the voltage between transformer windings under impulse conditions will not exceed the potential allowed by the arrester; this potential is so low that bushing flashovers or transformer failures should be practically eliminated. In proposing this the question naturally arises: Will such a connection introduce any additional hazard on the customer's premises and will it offer the advantage from the protection standpoint that apparently it should? Experience in those cases where this interconnection has been tried does not indicate any increased hazard, and the protection record seems to be far above that of the present connection.

In order that experimental data might be obtained under controlled test conditions, the General Electric Company conducted a field investigation in cooperation with the Associated Gas and Electric Company. The tests were made on a single-phase 4,600-volt rural line of the New York State Electric and Gas Company, built to serve the village of Willseyville, N. Y., and the surrounding community. The line had just been constructed at the time the tests were made and for most of the power tests was energized at 2,300 volts. A portable million volt impulse generator and a cathode ray oscillograph were used in the tests. A positive impulse voltage of 350 kv applied resulted in a 6/14 microsec wave with a crest of 123 kv at the test transformer location 4.45 miles away. To prevent flashover, it was necessary to increase materially the insulation at most of the guyed poles.

A 10-kva 2,300–115/230-volt transformer was mounted about 30 ft above ground on the pole at which the primary conductors terminated. The 3 secondary conductors $X_1$, $X_{23}$, and $X_4$ extended from this pole into the village of Willseyville, having a total circuit length of 3,273 ft located on 4 streets. (See Fig. 19.) A building which will be designated

### SE APPLIED TO THE PRIMARY

y results with impulses on both primary con-
s will be given as this is the most representa-
ondition of service and the conclusions drawn
equally well whether the impulse is on 1 con-
or both. Although nearly 1,000 oscillo-
were taken, in the limited space available
few of the data can be shown.

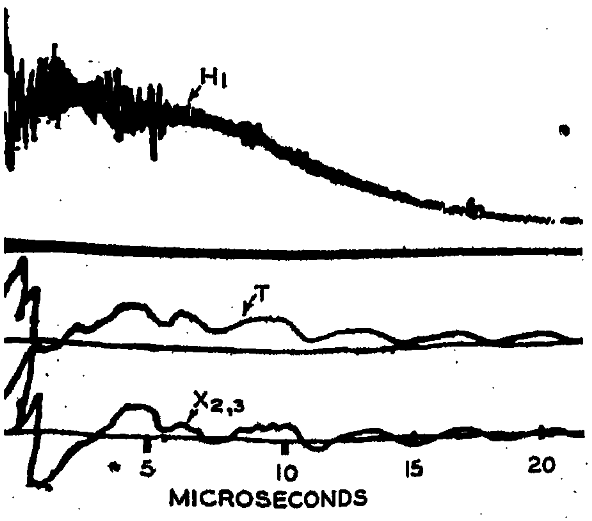
Oscillograms reproduced in Fig. 20 show the potential with respect to ground of the primary $H_1$, tank $T$, and secondary neutral $X_{23}$ with the 3-kv primary arresters connected to a 10-ohm ground in the usual manner. The secondary neutral potential remains close to ground potential while the tank takes an intermediate potential, but close to the secondary. As a result, most of the potential allowed by the primary arrester and its ground is impressed from the primary to tank and secondary.

Increasing the arrester ground resistance to 60 ohms increases the primary potential to tank and secondary and also increases the tank potential, as shown in Fig. 21. It is clear that further increase in arrester ground resistance is likely to result in either flashover of the primary bushings or a winding failure. Flashover of both primary bushings, or cascade flashover of a primary and secondary bushing, if the primary is grounded, is likely to result in blown fuses.

Interconnecting the arrester ground and secondary neutral greatly reduces the potentials between windings and from winding to tank as shown in Fig. 22. With this connection the oscillograms show that the tank and secondary have practically the same potential, while the primary to secondary potential is only the arrester potential, although the arrester ground resistance was 60 ohms.

In Fig. 23 the oscillograms of Figs. 21 and 22 are subtracted to show the great reduction in potential between primary and secondary when the arrester and secondary neutral were interconnected. Additional tests show that there is little difference of potential between the different windings even with the arrester ground disconnected. (Fig. 24.) Thus, regardless of the arrester ground resistance the transformer is well protected and fuse blowing is reduced to a minimum by eliminating bushing arcover.

Tests made using 6-kv pellet arresters with and without the tank connected to the arrester ground, which had a resistance of 10 ohms, are shown in Fig. 25. The oscillograms are replotted as they were taken with different time scales. The impulse was applied to both primary conductors, the secondary conductors still being connected to the secondary distribution system. The results show that the connection of the tank to the arrester ground



Potentials measured at the transformer when impulses were applied to the primary conductors. Primary lightning arresters grounded at the transformer pole in the usual manner

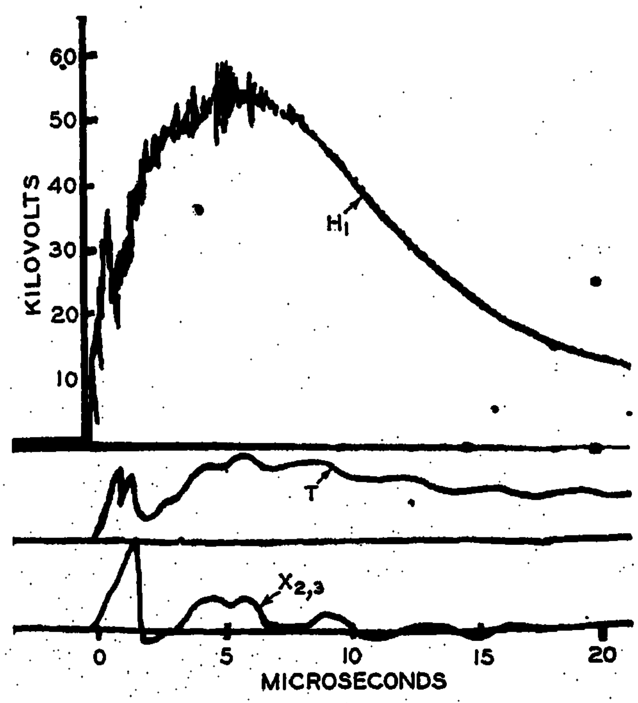
Oscillograms in each group have same calibration



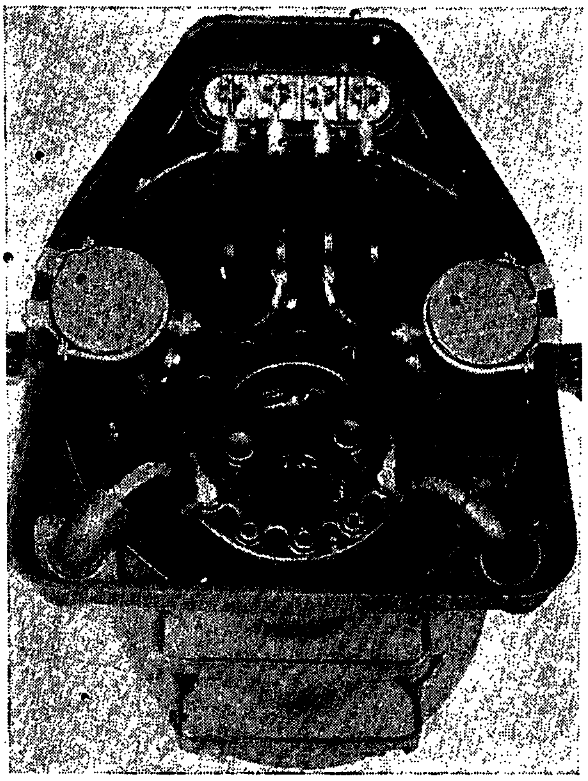


Fig. 28. Intershunt Thyrite lightning arresters mounted in a 25-kva distribution transformer for operation on a 2.4-kv isolated system

close to the transformer. Thus accidental connection between primary power supply and customer's premises should be practically eliminated.

5. Surge potentials at the transformer with the arrester ground interconnected to the secondary neutral is independent of the arrester ground resistance so that the transformer is protected whether the arrester ground resistance is high or low.

6. With the arrester ground interconnected to the secondary neutral, nothing is to be gained by connecting the transformer tank to the secondary neutral, since with the tank "floating," the potentials to tank are much less than the strength of insulation involved and the hazard to linemen is decreased.

7. Interconnection of primary arrester ground and secondary neutral allows impulse current to flow into the secondary network, the amount depending on the arrester ground at the transformer. The tests showed that even a 10-ohm ground did not prevent flashing some of the small gaps in the secondary house wiring; lightning discharges originating on the secondary do the same thing and interconnection increases the number of such discharges by the amount of exposure added. If a good arrester ground is used the severity of discharge in the secondary circuits will be reduced greatly. It is not believed that the increase in the number of discharges represents any increased hazard where the secondary neutral is connected to water pipe grounds, as in cities, even if the arrester is not grounded at the transformer. In rural distribution interconnection may represent some increase in hazard if several different grounds exist within consumer's premises so as to allow potential differences between different grounded objects and the secondary circuits.

8. From the standpoint of hazard due to power voltage, the present situation is that, in many instances of fuse blowing that may or may not have resulted from a transformer failure, power voltages of considerable magnitude appear between the secondary ground and separate grounds on the customer's premises; these voltages will persist until the fuse blows which may require many cycles, depending on the magnitude of the fault current. With good grounds on the secondary this time will be short and the voltage low; with poor grounds the time is longer and the voltage higher.

9. With the interconnection, it is believed that contacts between primary and secondary caused by lightning largely will be avoided thus materially reducing any hazard that may have existed before where the secondary ground resistance was high. In such cases the arrester probably should be connected to a ground at the point of interconnection to the secondary neutral.

10. The tests indicate that the record of arrester protection to distribution transformers, including fuse blowing, can be improved greatly by the interconnection, providing proper precautions are taken where the secondary neutral ground is not a water pipe ground; arrester grounds are not necessary where the secondary ground resistance is low as with waterpipe grounds.

## Additional Notes on Interconnection

Since the paper upon which the foregoing article is based was written, tests have been completed by Duvoisin and Brownlee ("Impulse Characteristics of Fuse Links," *G. E. Rev.*, May 1932, p. 260) which indicate that valve type lightning arresters may be connected inside of fuses without having the arrester discharge current blow the fuses. These tests show that in order to blow a 1-amp low temperature General Electric fuse link a 1.5/40-microsec impulse must have a crest voltage of at least 123 kv; to blow a 5-amp fuse under the same conditions the crest potential of the traveling wave must be at least 625 kv. Considering the insulation of most distribution circuits it is doubtful if fuses of a capacity as large as 3 amperes would be blown by the discharge current through a valve type lightning arrester. The effect of the power follow current through such an arrester is quite negligible from the standpoint of blowing fuses during a lightning storm.

With interconnection of lightning arresters it is essential that some means be provided for clearing the circuit in the event that the arrester should fail. Connecting the arrester inside the fuses provides a satisfactory method for doing this, and not only isolates the arrester but also locates the trouble so that it may be cleared quickly. The impulse tests on fuses show that this protection can be secured satisfactorily without any sacrifice in service reliability if fuses of 3-amp rating or larger are used.

There has been some discussion concerning the use of interconnection on circuits operating nongrounded, on account of the potential that might appear between the consumer's wiring and a separate ground. Available information indicates that on a 4.6-kv system the potential across a ground resistance of 100 ohms connected between one line and ground would not exceed 100 volts, the system being 20 miles in extent. This assumes, of course, that the line conductors are free from grounds. It does not appear, therefore, that the failure of a lightning arrester would cause any serious voltages on the consumer's premises even with a ground resistance as high as 100 ohms.

Several of the larger operating companies now are trying interconnection on a scale sufficiently large that the results taken as a whole should be quite conclusive. Some of these companies who have felt doubtful of the interconnection in relation to the various codes have obtained the approval of the engineers of the Public Service Commissions of their particular states.

### INTERSHUNT THYRITE LIGHTNING ARRESTER

If interconnection be employed it is convenient to mount the arrester inside the transformer tank so as to avoid external connections, thus decreasing the cost of installed protection and the amount of apparatus separately mounted on the pole. For this purpose a special Thyrite arrester has been developed consisting of an assembly of gaps and Thyrite within a sealed porcelain container and hung from the inside of the transformer tank. A transformer so protected is shown in Fig. 28. Such a location of the arrester insures the minimum length of leads and makes it possible for the arrester, which is connected between the primary conductors and secondary neutral, to function most efficiently. The arrester is mounted in such a way that the transformer tank is not a part of the circuit. Thus the tank can be grounded or left isolated as desired; if it be grounded it should be interconnected with the secondary neutral, so as to assure that the tank potential follows the secondary potential.

### COMMENTS CONCERNING INTERCONNECTION

Since the A.I.E.E. 1932 winter convention in New York, where the papers upon which these articles are based were presented, there has been much discussion concerning interconnection. This discussion may be more or less summarized in the statement that improvement in protection to the transformer and reduction in blown fuses will result, but where driven secondary grounds are in use, there may be some question concerning hazard. It seems to the writers that the case for interconnection versus the arrester ground connection can be stated in some such fashion as the following: With the arrester ground connection the protection of the transformer and the quality of the service depend upon the arrester, the ground resistance, and length of ground lead, while the safety of the consumer depends upon the quality of the secondary grounds. If the secondary ground resistance is high the consumer's safety also may depend upon the arrester and ground resistance as these may determine whether or not a primary-secondary contact is to be established. With interconnection the protection of the transformer depends upon the arrester only, while the safety of the consumer depends upon the quality of the secondary grounds.

Any arrangement which tends to make the secondary ground better is to be preferred, and of course this includes the interconnection of secondaries into a grid and also the interconnection of the primary neutral and the secondary neutral. Such connections establish a firm ground with many connections to ground, and should result in improved reliability both from the standpoint of lightning protection and hazard to the consumer.

---

# Wiring Buildings for Good Illumination

**Progress in securing good illumination in buildings has been impeded seriously by lack of sufficient wiring capacity. The situation is reviewed in this paper in the hope of stimulating engineering interest and thus promoting wider use of practises which will insure reasonable prospect of adequacy of lighting circuits throughout the life of a structure.**

CONTEMPORANEOUSLY with the development of lighting practise there has come into existence a group of illuminating or lighting service engineers associated with utility companies, leading lamp and equipment manufacturers, and some of the large users of light, who have interchanged data and experience with each other as well as with practising consultants.

A large measure of the effort of these engineers has been devoted to the repair and correction of lighting installations which for one reason or another have proved unsatisfactory in operation. They therefore have had an unusual opportunity of determining the border lines of satisfactory and unsatisfactory lighting. It is this experience, embodied in the criteria and rules for lighting practise, that has rendered the practise so reliable and secured its wide acceptance. While this experience has been dominantly with the smaller installations, in which for economic reasons paid consultants are not usually retained, it should be borne in mind that the more elaborate installations have at least as stringent requirements.

### LIGHTING PRACTISE ADVANCING

The lighting practises developed have been expressed in papers and reports before various associations. Notable among these are the lighting codes of the Illuminating Engineering Society, the American Standards Association, and the International Commission on Illumination. The accepted illumination levels for the most common conditions of building lighting have been compiled in tabular form by leading illuminating engineers. Among other places these tables have been published in the Franklin "red seal" specification of the Society for Electrical Development, which also prescribes approximate rules for the lighting design of the simpler and more common classes of building interiors. This specification is probably the simplest, most condensed, and most comprehensive expression of present lighting practise; thus it furnishes a reasonable expression of the electric power requirements of that practise.

---

Based upon "Adequate Wiring of Buildings, an Essential for Good Illumination" (No. 32-86) presented at the A.I.E.E. summer convention, Cleveland, Ohio, June 20–24, 1932.

While electric lighting practise in the more common applications is comparatively definite, it is not static. Illumination levels, that is to say, the quantitative elements, have been rising steadily for many years and except for the retardation during periods of business depression, there is no indication that most fields have approached saturation. Moreover, there is an increasing demand for diffusion and reduction of glare which is generally secured at a sacrifice of light and therefore puts an additional requirement on the amount of electricity to be supplied.

While qualitatively these advances are generally recognized, it is exceedingly difficult to secure any quantitative measure for them, due to variations in application, locality, time, etc. Probably the best authoritative values for industrial lighting are published in the 1921 and 1930 issues of the "American Standard Code of Lighting for Factories, Mills, and Other Work Places," which have been published in pamphlet form and in the *Transactions* of the I.E.S., v. 16, 1921, p. 362 and v. 25, 1930, p. 607. The 2 issues give the values in different form and in some instances different classifications. However, a few samples have been selected and incorporated in Table I. It is probable that in most instances the advances are, if anything, greater than here indicated as the later values were presumably more widely exemplified in actual installations at the time of issue. It seems safe to say that, in general, the decade ending in 1930 witnessed approximately a doubling of light requirement for good practise in the principal classes of commercial, industrial, and office lighting.

**Table I—Illumination Levels Good Practise**

| Class of Operation or Interior | Foot-Candles | |
|---|---|---|
| | 1921 | 1930 |
| Assembly—rough | 2 to 5 | 8 to 5 |
| —medium | | 12 to 8 |
| —medium fine | 5 to 10 | |
| —extra fine | 10 to 20 | 100 to 25 |
| Chemical works—hand furnaces, etc | 2 to 5 | 5 to 3 |
| Cloth products—light goods | 5 to 10 | 15 to 10 |
| —dark goods | 10 to 20 | 100 to 25 |
| Elevators—freight and passenger | 2 to 5 | 8 to 5 |
| Forge shops | 2 to 5 | 10 to 6 |
| Foundries—charging floor | 2 to 5 | 8 to 5 |
| —fine molding and core making | 5 to 10 | 15 to 10 |
| Glove manufacturing—dark goods | 10 to 20 | 100 to 25 |
| Locker rooms | 2 to 5 | 6 to 4 |
| Machine shops—rough work | 2 to 5 | 10 to 6 |
| —medium work | 5 to 10 | 15 to 10 |
| —fine work | 10 to 20 | 100 to 25 |
| Offices—close work | | 15 to 10 |
| —no close work | | 10 to 8 |
| —private and general | 5 to 10 | |
| —drafting | 10 to 20 | 25 to 15 |

## INDICATIONS OF WIRING INADEQUACY

For a number of years illuminating engineers have been encountering installations in which suitable lighting could not be provided because of a lack of capacity in the wiring. Even where the safe carrying capacity of the wiring was not exceeded, excessive losses of electrical pressure in the wiring were frequently encountered so that the voltage delivered to lamps was considerably less than it should have been. Such losses were greatest at times when the demand was greatest, and resulted in serious reduction in light output and lamp efficiency. In a brief survey made in 1931 by an electric utility company in Ohio, it was found that the voltage drop in the interior wiring between meter and socket was frequently over 5 per cent and in some cases in excess of 10 per cent. Since operation of tungsten filament lamps at 10 per cent of rated voltage means a light output of only about 70 per cent of normal (see Fig. 1), it is easy to understand how unsatisfactory the illumination would be. This subject is discussed further in "Voltage and Incandescent Electric Lighting," G. S. Merrill, Preprint No. 137, International Illumination Congress, presented at Glasgow, September 1931. Oftentimes such conditions have been misinterpreted as being due to poor regulation of the utility's circuits or to defective lamps and have been a source of complaint from this standpoint. In extreme cases building owners have been compelled to incur the costly outlay of rewiring, but in a much larger number of cases, the expense has appeared prohibitive, and unsatisfactory lighting has been continued.

A review of the papers and reports presented before engineering associations shows careful treatment of practically every phase of electrical engineering except building wiring. It seems important that more attention be given this subject.

## FUTURE LIGHTING

In addition to the expected advance in illumination levels and degrees of light diffusion, there is a number of more or less new lighting applications going into use which bid fair to increase the electrical consumption. Among these may be mentioned light ornaments, that is, light sources to look at rather than for general illumination, ornamental portable lamps, indoor signal indicators, signs, etc. Some of these, while originating in the home, club, or hotel, are spreading to stores, offices, and other interiors.

For the past 5 years, the practise initiated in Europe of using so-called "built-in" lighting has been spreading rapidly in this country. Since such lighting formerly required special construction in the walls and ceilings, it was applicable only to new buildings or those in which extensive reconstruction was being undertaken. However, modified forms of luminaires similar to built-in equipment are beginning to appear, and these can be installed without difficulty in finished rooms and supplied from the usual electric outlets. This class of lighting is extending because of its artistic merit and in spite of a considerable reduction in efficiency measured in lumens per watt. It therefore represents an increase in electrical consumption which should receive proper consideration.

Another phase of lighting, which is still in the experimental stage but receiving enough attention to preclude ignoring it, is the so-called "dual purpose" health lighting. In addition to the visible light, these lamps supply the ultraviolet radiation which is depleted from daylight by window glass and city smoke and which is absent from the light of ordinary illuminants. Such equipment does not inherently require more electricity per unit of light than ordinary lighting, but the installations so far made indicate a tendency to employ higher wattage.

A compensating factor to the increased consumption would be the use of more efficient light sources. The rapid increase in efficiency of incandescent lamps from, say, 1912 to 1922 just about kept pace with the demand for more light, so that the electrical demand for a given area and purpose held fairly constant throughout that period. Since then the advance in efficiency has slowed down and although illuminants of considerably higher efficiency have been produced in laboratories, it appears unsafe to depend upon any great increase in efficiency being widely applicable to today's installations within the next 4 or 5 years.

Within the past 10 years large numbers of small motor and heating appliances have been connected to lighting circuits and apparently the next few years will witness considerable increase in the load due to their more extended use. They are valuable services and must be planned both for their own value and for the limits they otherwise would present to good lighting practise.

## THE QUANTITATIVE ELEMENT OF WIRING

Interior wiring has received a great deal of attention on the part of code writers, and has been the subject of numerous rules. By many in the electrical industry the National Electric Code has been taken as a standard of good engineering, overlooking the fact that the purpose of the code is fire prevention and other safety features. Being mandatory in character, the code cannot prescribe wiring on the basis of economic engineering. Because of the common failure of those responsible for such wiring to provide for later additions to the load it has been necessary for the code to anticipate these additions, but still on the basis of safety only. The code has been the subject of considerable controversy among the various interests involved. Since good engineering would incorporate both the requirements for safety and economic operation, there is good reason to believe that if good engineering were to prevail in this field these misunderstandings would disappear and the code assume its rightful position.

In the absence of generally accepted standards other than the wiring code, it has become a widespread practise for designers to establish arbitrary rules and constants of their own making. In the smaller installations the details of wiring are often determined by competing contractors eager to underbid each other. Where consulting engineers are retained, they often are urged to justify their employment by minimizing investment and so find it difficult to apply best engineering judgment. These varying circumstances all militate against the proper response of wiring practise to the needs of lighting.

In the report of a National Electric Light Association subcommittee on adequate wiring entitled, "Lighting Service Manual," Part 3, p. 17, published by the N.E.L.A., August 1928, the following conclusions were drawn:

1. That to cut down the wiring specifications in order to reduce the initial investment was false economy as the greater losses would within a period of a year or 2 entirely offset the difference in investment.

2. That the investment in the wiring system did not increase in direct proportion to the increase in wiring capacity; doubling the wattage capacity increased the investment only about $^1/_3$ while 50 per cent extra capacity meant an additional investment of only from 15 to 18 per cent.

It would appear therefore that in the interest of good engineering based upon economics what is needed is a reasonable standard, based upon good lighting practise, with an allowance for advances in the art and probable changes in the use of buildings. Such a standard would do much to overcome the insidious whittling which, in a considerable degree, has been responsible for the unsatisfactory condition.

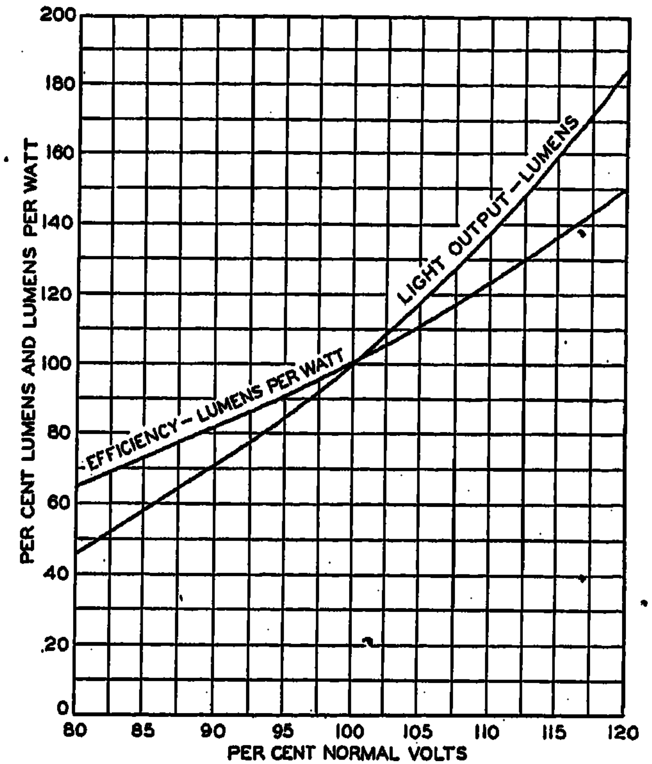

**Fig. 1. Relation between illumination and voltage of tungsten filament lamps**

## ADEQUACY SPECIFICATION

A few illumination engineers about 1924 became conscious of building wiring as a limitation of good lighting. Previous to that time these engineers had concentrated upon the selection of lamps, luminaires, and locations. It became obviously important to give attention to wiring if the advance of illuminating engineering were not to be seriously impeded. The educational undertaking which resulted is described in "Adequate Wiring—A Problem of the Illuminating Engineer," G. H. Stickney, Preprint No. 125, International Illumination Congress, presented at Glasgow, September 1931.

Through the efforts of the N.E.L.A., preliminary paragraphs for an adequacy specification were agreed upon in the spring of 1929. Immediately some of the illuminating engineers, especially those associated with electric utility companies, began an informal application of the standards so embodied. The results were very gratifying. After a year's experience an extension of these paragraphs for commercial buildings was published by the N.E.L.A. in the pamphlet of March 30, 1930, entitled, "Minimum Specification for Adequate Wiring of Lighting Circuits in Commercial and Public Structures." A corresponding specification for industrial buildings was issued under the same auspices on July 20, 1931, entitled, "Minimum Specification for Adequate Wiring of Lighting Circuits in Industrial Structures."

Several interested groups individually undertook the preparation of corresponding specifications for residence wiring, and in the fall of 1931 an industry committee was organized to coordinate the several undertakings into a single standard specification. This work is not yet completed, although the reports indicate that the end is in sight.

It is to be hoped that consulting engineers will familiarize themselves with these specifications and subject them to criticism, and that out of this there may come generally accepted standards of wiring practise. This would strengthen the weak link in the system of electric lighting, and encourage a normal development along the line of good engineering based upon economics. The public then could look with confidence to its advisers in the field of electric lighting, and be assured that good illumination, according to its needs, could be had in any building constructed under responsible auspices.

# A Railway Motor Without Commutator

**One of the latest uses for that versatile device, the grid controlled mercury arc rectifier, is to replace the commutator of an electric railway motor that will operate on either alternating or direct current. However, the rectifier eliminates not only the commutators in a locomotive equipped with these motors, but also all expensive control, switching, and reversing equipment. Experiments have shown so much promise that a 1,000-hp locomotive of this type now is being built in Switzerland.**

By
OTHMAR K. MARTI
MEMBER A.I.E.E.

Allis-Chalmers Mfg.

EXTENSIVE research work carried on for improving the mercury arc rectifier has led not only to improvements in its operation but also to entirely new applications of the device, and to new applications of the valve action on which its rectifying property is based. In recent years considerable experimental and development work has been carried out on rectifiers provided with control grids, utilizing the grids for interrupting short circuits and backfires, for d-c voltage control, for the conversion of direct current to alternating current, and for many other purposes. In this paper is described a new application of grid controlled mercury arc rectifiers in connection with a new single-phase commutatorless motor for a-c railway service.

Experiments carried out on a locomotive equipped with this type of motor have demonstrated the practicability of this scheme. Besides the elimination of commutators, practically all of the expensive switchgear and control apparatus is done away with, resulting in a simplification of the locomotive and a reduction in cost. In addition, it becomes possible to use a power supply of any available frequency, whereas at the present time frequencies of 25 cycles or less generally are required. While it is too early to predict where this development may lead, the marked advantages of a locomotive equipped with motors of this type, which are already apparent, may revolutionize the practise of railway electrification.

## OPERATION OF ENERGIZED GRIDS

Phenomena and characteristics of the mercury arc valve have been treated in great detail in various scientific journals. Its applications are many if equipped with a control grid which is introduced into the path of the arc. This grid is insulated from the anode and may be energized from an outside source of potential, such as a battery, auxiliary transformer, generator, or a combination of these sources. Non-energized grids or screens also are used to a large extent in mercury arc rectifiers for many purposes. (See "Mercury Arc Power Rectifiers," Marti and Winograd, McGraw-Hill Book Co., p. 42, 227, 232, 397.)

Some of the possibilities of energized grids are illustrated by the diagram of a 2-anode rectifier shown in Fig. 1. Let a sinusoidal a-c voltage be impressed on the primary side of the transformer, and let the grids be de-energized. The anodes will be positive during alternate half-cycles. During the half-cycle that anode 1 is positive, current will flow from anode to cathode through the load circuit, as indicated by the solid arrows. When anode 2 is positive, current will flow from anode to cathode through the load circuit, as shown by the dotted arrows. The current therefore flows through the load circuit in the same direction during both halves of the cycle. The same rectifying action will take place if a positive potential is applied to the grids during the intervals when the voltages of the corresponding anodes are positive. This could be accomplished by throwing switch *S* (Fig. 1) from one position to the other after each half-cycle, making the grid of anode 1 positive during the half-cycle when anode 1 is positive, etc., or by rotating commutator *C* at synchronous speed by means of motor *M*.

This is illustrated in Fig. 2. Section *a* shows the

---

Based upon "The Mercury Arc Rectifier Applied to A-C Railway Electrification" (No. 32-63) presented at the A.I.E.E. Great Lakes District meeting, Milwaukee, Wis., March 14-16, 1932, and subsequently revised and brought more fully up to date.

anode voltages $e_{10}$, $e_{20}$. Shaded portions represent the d-c voltage wave (neglecting the arc drop). Section *b* represents the d-c wave for a resistance load. Sections *c* and *d* indicate the potentials applied to the grids; shaded blocks represent the potentials if direct current is used, with a reversing or rotating switch, as shown in Fig. 1, and the sine waves represent the potentials if alternating current is used.

In *A* of Fig. 2 is shown the condition when the grids are made positive at the instant when the corresponding anodes become positive. Each anode then operates during half a cycle, and the average d-c voltage is shown by line $E_{dA}$. In *B* of Fig. 2 is shown the condition obtained by shifting the brushes of the rotating switch *C*, Fig. 1, through the angle $\alpha$. The grid potential then becomes positive $\alpha$ electrical degrees after the anode potential, and the point at which the anodes start firing is delayed by the angle $\alpha$, which reduces the d-c voltage to the average value $E_{dB}$.

It can readily be seen that by shifting the brushes of commutator *C*, that is, by changing the timing with respect to the voltage of the anodes, the rectifier can be stopped from passing current without interrupting the primary supply or the voltage can be changed from the maximum value $E_{dA}$, to a value $E_{dB}$, or can be made as low as zero. The source of potential for energizing the grids, battery *B*, can be replaced by an a-c source, which could be an auxiliary transformer, a small generator, or the like. Several standard rectifiers equipped with such grid control have been built at the West Allis works of the Allis-Chalmers Manufacturing Company and recently were placed in service. They have proved entirely satisfactory.

Only a few hundred watts are required for controlling power rectifiers. The grid control apparatus is therefore quite inexpensive. This fact should be born in mind when studying the commutatorless motor and locomotive described later in this article.

## INVERTED RECTIFIER

In the arrangement shown in Fig. 1, assume that the load is replaced by a d-c generator as shown. If a positive voltage is applied to the grid of anode 1, current will begin to flow through the left-hand portion of the secondary winding of the transformer, inducing a voltage in the primary winding. After a certain time interval let the grid of anode 2 become positive, and current will start to flow through the right-hand portion of the secondary winding of the transformer. If at the same time the current in anode 1 can be reduced to zero by some means or other, then the rectifier and associated equipment would be nothing else than a converter feeding power from the d-c into the a-c network. Although the flow of current from generator *G* through the anodes can be controlled by energized grids only as to the time of starting, other methods have been developed for reducing the anode current to zero in the proper sequence to obtain inverted operation of a conventional rectifier so as to convert direct current into alternating current. (See Kern, *Bulletin Schweizerischer Elektrotechnischer Verein*, 1931, p. 538.)

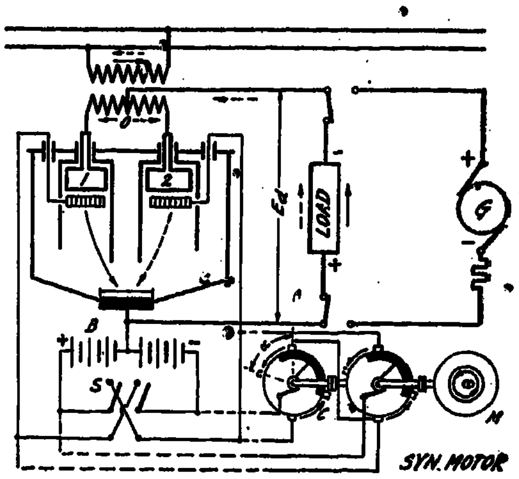

**Fig. 1. Controlled-grid valve that can be used either as a rectifier or a d-c to a-c converter**

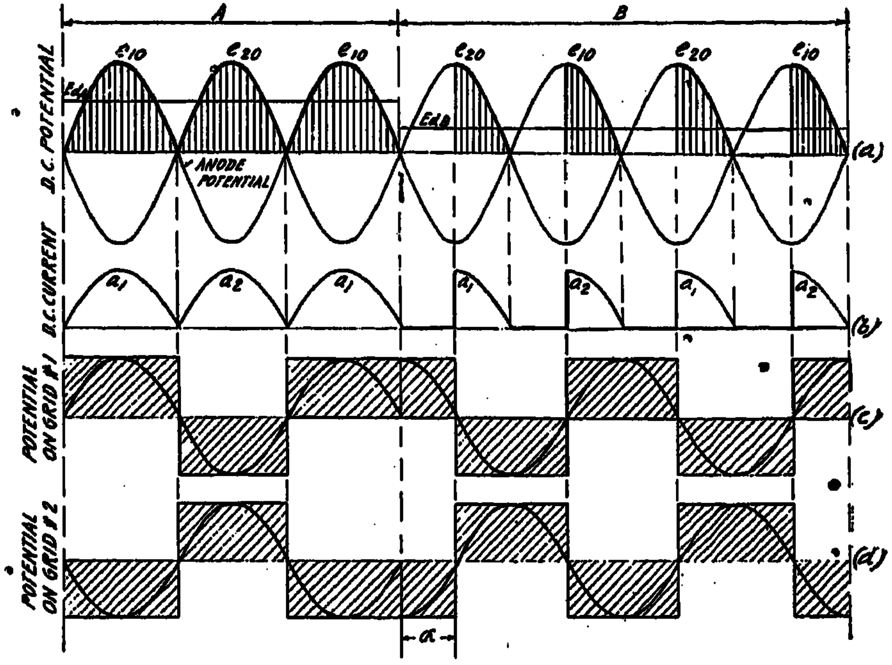

**Fig. 2. Curves illustrating voltage regulation and control by means of energized grids**

This feature opens up great possibilities for the now fully developed mercury arc rectifier, and many new applications for the mercury arc valve.

## COMMUTATORLESS SINGLE-PHASE RAILWAY MOTOR

For some time portable substations equipped with mercury arc rectifiers have been built abroad and in this country. As far back as 1914 a 250-hp motor car, equipped with a mercury arc rectifier, was in service in this country, on the New York, New Haven, and Hartford Railroad. As some experience therefore already is at hand, it will not be a novelty to put a rectifier on a locomotive, except in its use as a static commutator for the traction motors.

Present standard series a-c or d-c traction motors are limited to comparatively low voltages by their commutators, and therefore the controls for these motors are expensive. The commutator also makes the construction of the motor expensive, and involves the troublesome difficulties inherent in mechanical commutation. It has been found possible to replace the commutator by a series of electric valves, *viz.*, a mercury arc rectifier, by the use of which the disadvantages mentioned are obviated. This scheme can be applied to single-phase or d-c motors so that relatively high voltages can be used, thus reducing the size and weight of the copper used in the connections. At the same time, a very desirable speed-tractive effort characteristic can be obtained. Furthermore, all expensive control, switching, and re-

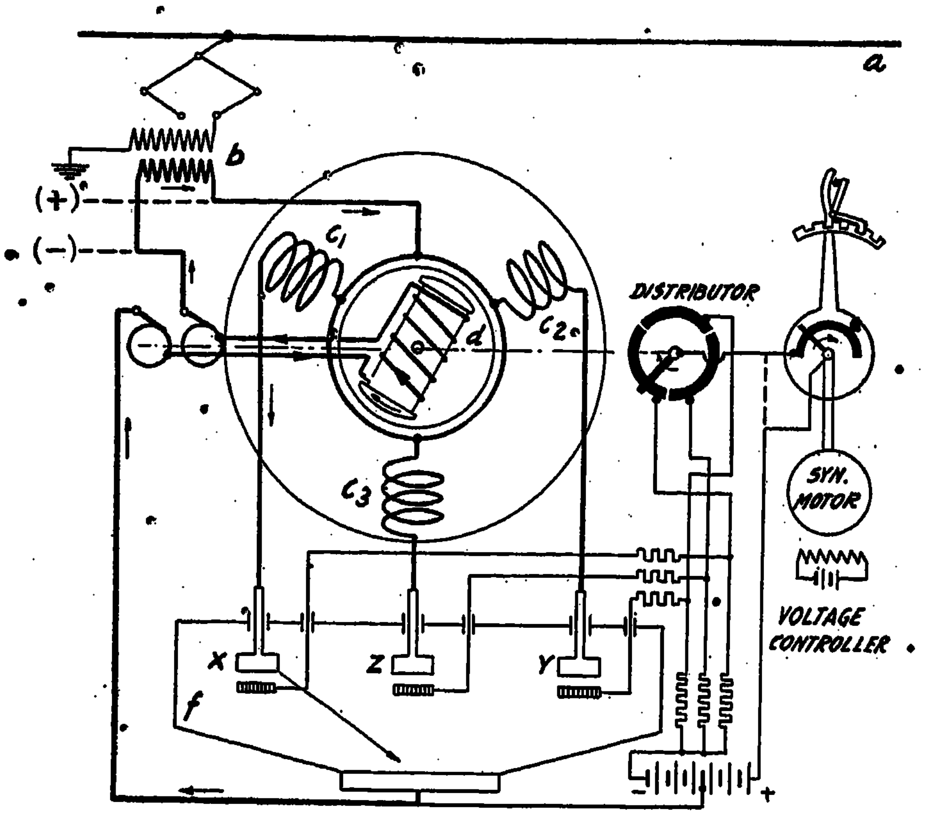

**Fig. 3. Elementary commutatorless motor**

versing equipment is dispensed with, while a rectifier and a very simple and cheap grid control is added.

Referring to Fig. 3, it may be seen that the commutatorless motor consists of an armature winding $c$, a field winding $d$, and a distributor mounted on the shaft of the motor. An integral part of the motor is the grid controlled rectifier $f$. The complete outfit includes, in addition, a single phase transformer $b$, a synchronous rotary switch, and the control battery; $a$ is the trolley wire. The armature windings of the motor are in the stator and the field winding is on the rotor for the same reason that this practise generally is followed in the design of synchronous motors. By doing so only 2 slip rings are necessary for the field windings, whereas if the armature were wound on the rotor 4 slip rings would be required in this particular case, and even more for practical applications.

In order to understand the function and operation of the distributor, assume for a moment that the armature is on the rotor and that the field is in the stator. The distributor then corresponds exactly to the conventional commutator of a d-c machine, that is, it distributes or shifts the current from one armature coil to the next at the proper moment, just as the conventional commutator does in a conventional motor. However, instead of carrying the total armature current, or, as in a series motor, the total motor current, the distributor has to handle only a very small current—a fraction of an ampere; it controls the rectifier which carries the full motor current and performs the actual commutation. Now, considering this motor again as it actually would be built with the armature stationary and the field fed by slip rings, it is evident that the distributor still performs the functions of a commutator. In other words, the distributor controls the flow of current through the various coils of the armature winding as a function of the position of the rotor just as a conventional commutator would do the same thing, and has no effect on the speed of the motor.

In operation, let it be assumed, first, that the rectifier equipment is in the position shown, and that one grid (of anode $x$) is energized positively through the distributor. This grid accordingly permits current to flow through the anode which it controls. All other grids will be energized negatively thus preventing current from flowing through their anodes. As the primary winding of transformer $b$ is energized from the line, a half-wave current will flow through the winding of rotor $d$ and through $c_1$, as indicated by the arrows. As can readily be seen, the field produced in the windings $c_1$ and $d$ will produce a torque which causes the field $d$ to rotate. At the proper time, the shaft of the motor $e$ brings the brushes of the distributor to such a position that the grids of anodes $z$ and $x$ now are energized negatively, while the grid of anode $y$ is energized positively, permitting current to flow from anode $y$ into winding $d$, and through $c_2$. This process is repeated in sequence for all windings of the stator, thereby producing a continuously rotating motion of the rotor.

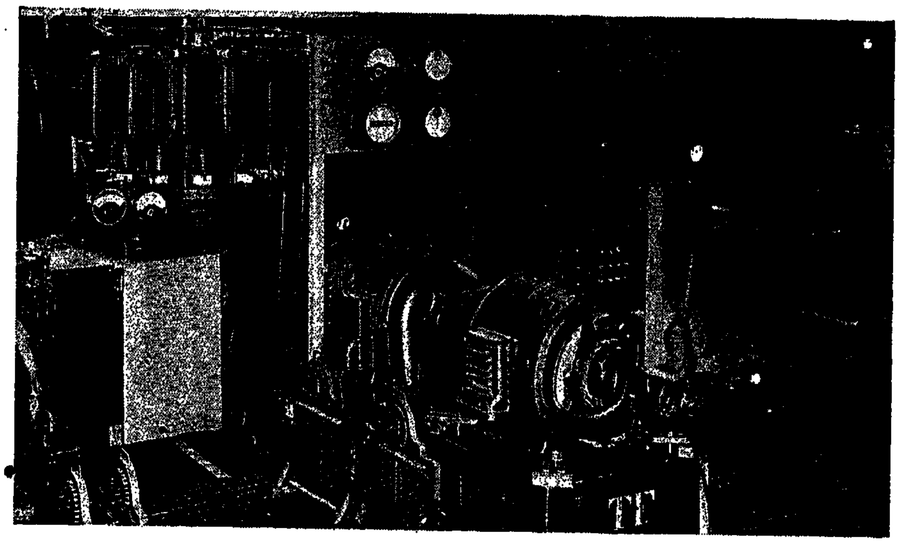

**Fig. 4. Commutatorless rectifier motor on test**

## CONTINUOUS SPEED CONTROL

The speed of the motor is determined by the same factors which determine the speed of any series motor, whether d-c or a-c, namely, the load on the motor and the voltage across it. In the case of a d-c series motor, the voltage across it would be determined by the series resistance, which can be cut in or out in steps; a-c series motors are controlled similarly by means of resistances or taps on an auto-transformer. Both of these schemes have their obvious disadvantages as follows:

1. The speed is regulated in steps.
2. A considerable loss in energy generally is involved.
3. The control apparatus is expensive, becoming more expensive as the number of steps is increased.

In the commutatorless motor, continuous speed regulation can be obtained without loss of energy and with inexpensive equipment. In Fig. 3 may be seen a rotary switch called the voltage controller, driven by a small synchronous motor from the main supply. This voltage controller prevents the formation of an arc in the rectifier before a certain point in the cycle of the voltage wave. This point can be determined by shifting the position of the stationary contact of the voltage controller so that the anode can be made to pick up at the very beginning of the positive half of the voltage wave, or can be entirely prevented from picking up. Any intermediate position, of course, can be obtained. Referring to the explanation of voltage control of rectifiers by means of energized grids, it may be seen that actually the average voltage across the motor is being controlled. By this mean speed regulation of the motor is obtained, and it is evident that this regulation is continuous from zero up to the speed for which the motor is designed. It is evident also that the same voltage controller can be used for starting the motor.

The motor illustrated in Fig. 3 utilizes only one half of the applied voltage wave, and hence would not be considered in a practical case. A connection therefore is used whereby the full wave is utilized. Moreover, the armature windings are arranged so that although each conductor carries only a pulsating unidirectional current, each pole is energized continuously for 180 electrical rotor degrees in one direction, and in the other direction for the next 180 degrees. Magnetic conditions in the motor therefore are the same as in a d-c machine, and there is no tendency for the motor to "lock in" at synchronous or sub-synchronous speeds.

This motor has a series characteristic which is desirable for traction purposes. A resistance can be connected across the stator winding, so that the motor can be given the characteristics of a repulsion motor. It is also possible to connect only the rotor to the source of power, in which case the stator circuits are closed only through the rectifier, and the stator currents are obtained by induction through the rotor. The stator, being then no longer connected to the circuit, can be wound for whatever voltage is found most desirable. (See Kern, *Elektrische Bahnen*, November 1931.)

## Motor Can Operate From Direct Current

Considering the magnetic conditions in the commutatorless motor, it can be shown that a motor can be designed to operate from a d-c source. The counter emf is used to enable the rectifier to commutate the current from one armature winding to the next. During the starting period, before sufficient back emf is available, a small auxiliary machine supplies the commutating voltage. It is possible to design a motor which will operate either on 25 or 60 cycles, or on direct current. A locomotive therefore can be designed which will operate on, say, 11,000-volt, 25-cycle main lines, and also on 3,000-volt d-c systems in metropolitan areas.

Summarizing, we have a motor which can be used either on 25 or 60-cycle systems or on high voltage direct current. Starting and controlling the motor is effected by controlling the average d-c voltage across the motor without loss of energy. The motor is reversed merely by shifting the stationary contacts of the distributor 180 electrical degrees. Regenerative braking is obtained by shifting the distributor and voltage regulator. Thus all control operations, starting, running, reversing, and braking of the loco-

motive, are accomplished by shifting the stationary contacts of the voltage controller and of the distributor, both of which are small pieces of apparatus.

In Fig. 4 is shown the first experimental model of such a commutatorless motor directly coupled to a generator as load, and with a commercial rectifier of large capacity. The control hand-wheel is visible on the right.

In conclusion it is of interest to note that Brown, Boveri & Company, Ltd., of Baden, Switzerland, at present is building a single-phase locomotive to be operated directly with single-phase power of 50 cycles at 15,000 volts. The locomotive is of standard gage, and is equipped with two motors of 500 hp, one-hour rating, for a maximum speed of 90 km per hr (56 mph). (See Fig. 5.) It is designed for regenerative braking. This locomotive has no commutators, tap switches, starting resistances, or reversing switches, in the motor circuit. All such equipment is replaced by a high-voltage mercury arc rectifier with control grids. Tests with this locomotive will be highly significant in view of the possible utilization of alternating currents of commercial frequencies for the electrification of main line railroads.

# The Rock Island Hydroelectric Development

**First electric power development on the famous Columbia River, the initial 60,000-kw Rock Island plant also is the first major low head installation on the Pacific Coast, a territory long famous for its high head plants, and has the largest installed capacity in adjustable-vane propeller-type wheels of any plant in the United States. Some of the project's many departures from conventional design are revealed in the accompanying text and illustrations.**

By
A. P. NEWBERRY

GEORGE C. SEARS
MEMBER A.I.E.E.

Both of
Puget Sound Power &
Light Co., Seattle, Wash.

THE ROCK ISLAND hydroelectric plant is being built as a unit of the Puget Sound Power & Light Company's system which supplies electric service to a large territory lying west of the Cascade Mountains in the State of Washington. The development is interesting in that it is the only large low head plant in a section where high heads are the rule and therefore presents certain features of design that generally are not found on the Pacific Coast. Further, it is the first step in the development of the enormous power resources of the Columbia River, one of the most famous streams in North America.

The plant is located east of the Cascades on the Columbia River in central Washington about 13 miles downstream from Wenatchee. From the plant 2 130-mile 110-kv transmission lines cross the mountains through widely separated passes to connect at different points with the company's system around Puget Sound where the major portion of the station's output will be used. The main power supply of the system at present is from hydro plants on the west side of the mountains supplemented by a relatively new 80,000-kw steam-electric generating station in Seattle. While there is some diversity in the various rivers due to the different altitudes of their watersheds, they all have the characteristics typical of glacially fed streams, high water in the spring and summer and low flow in the fall and winter. Even with appreciable amounts of storage available to fill in the low periods, there is a natural reduction in hydro capacity at those times requiring the operation of steam stations to make up the deficiency. Conditions at Rock Island are such that, with maximum capacity and output available at low water and the reduction in both occurring at high water, this plant fits in admirably with the other stations.

## WATER SUPPLY

The Columbia River at the dam is fed by a drainage area of some 90,000 square miles extending from the Cascade Mountains on the west to the Rockies on the east, and including parts of Washington, Idaho, Montana, and British Columbia. Precipitation in the upper Columbia watershed varies from less than 15 in. in eastern Washington to nearly

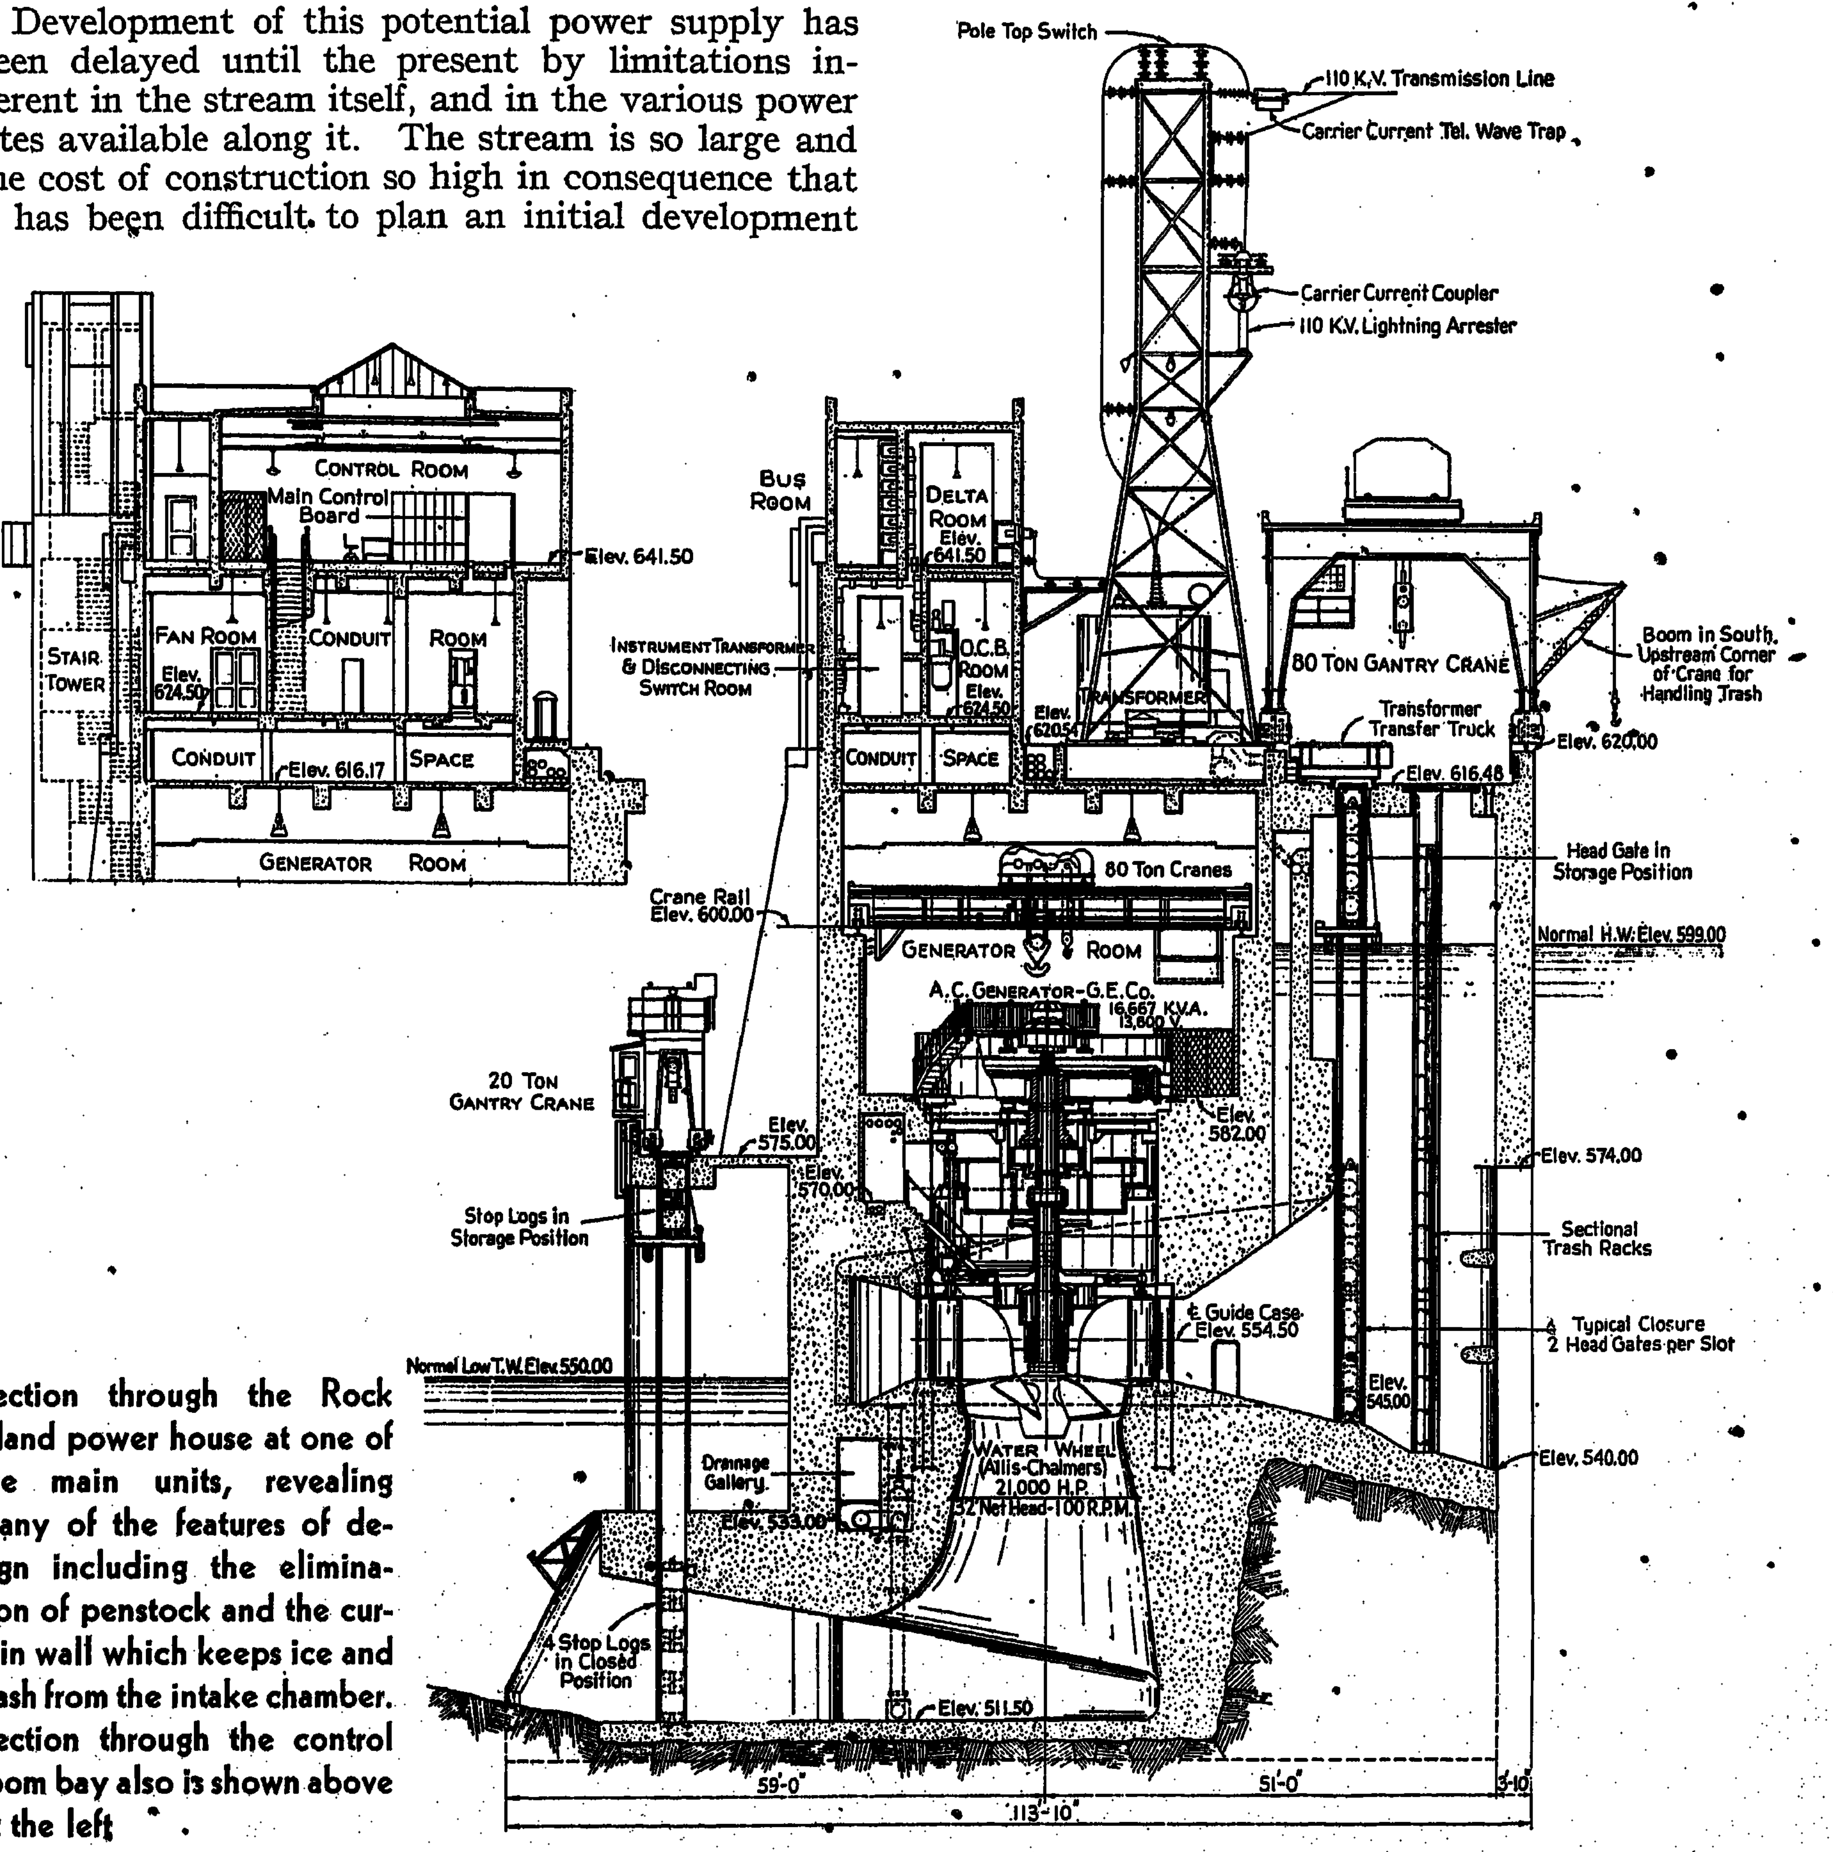
---

C., Aug. 30–Sept. 2, 1932, as enlarged and rewritten especially for ELECTRICAL ENGINEERING through the cooperation of the Stone & Webster Engineering Corporation, Boston, Mass. *Not published in pamphlet form.*

100 in. in British Columbia. This upper portion of the drainage area includes many lakes and glaciers, and mountain ranges almost perpetually covered with snow. Nearly all the precipitation on the entire watershed comes in the winter in the form of snow which lies on the ground until spring. Hence from October 1 to April 1 the supply is almost entirely ground water, maintaining a remarkably uniform flow averaging about 40,000 cfs and rarely exceeding 100,000 cfs. As the snow melts, beginning usually about April 1 on the lower lands and gradually extending to the higher levels, there is a discharge steadily increasing to a maximum about the middle of June. This maximum varies widely from year to year depending upon the amount of snow in storage and the rate of run-off. The maximum flood on record since 1858 was 740,000 cfs in 1894; the lowest recorded flow about 21,000 cfs.

Development of this potential power supply has been delayed until the present by limitations inherent in the stream itself, and in the various power sites available along it. The stream is so large and the cost of construction so high in consequence that it has been difficult to plan an initial development that would show good economy. The opinion generally held has been that any Columbia River water power development would require a market larger than could be furnished by any one of the adjacent power systems. Further, the nature of the river channel below the dam is such that, with increasing flow, the water level below the dam rises much faster than the level above, until, with extreme floods, the differential may be less than 20 ft. However, this reduction in head and consequently in plant capacity, comes at a time when all other plants on the system are at their best in productive capacity, and therefore is not a handicap to economical operation.

The Columbia basin in eastern Washington is underlaid by basaltic formation made up of separate layers or flows of lava superimposed one above the other. In general, these layers are horizontal and



**Section through the Rock Island power house at one of the main units, revealing many of the features of design including the elimination of penstock and the curtain wall which keeps ice and trash from the intake chamber. Section through the control room bay also is shown above at the left**

in much the same position as when first deposited. One of these sheets of basalt forms the rapids at Rock Island, and is the foundation on which the dam is built. (See front cover.) Chief among the advantages that led to the selection of this location are (1) good foundation and favorable topography; (2) proximity to a transmission line already constructed; (3) site on the main line of the Great Northern Railway; (4) amount and character of available power is such that it can be utilized economically by the power company.

THE DAM

The dam is a concrete structure built to develop an effective head of 32 ft at its initial height. Ample water is available for full capacity of the present installation at that head, but with the addition of more units the dam will be raised to give an effective head of 48 ft. Spillway capacity sufficient to pass extreme floods is provided by 37 gates each 30 ft wide, 18 of which have their sills at el 559.0, and the remainder at el 581.5. In the initial development a free crest at el 581.5 will be maintained by using gates to that height in the deep slots, except in very high water when some of these gates will be opened to hold the pond level within the project boundary. With the installation of more units, piers will be raised and gates placed to el 599.0 to provide the 48-ft head.

Requirements laid down by the Federal Power Commission in its construction license covering the project called for a design that would provide immediately for the free passage of salmon over the dam, and provide ultimately for the possible development of the upper Columbia River as a navigable stream. At present there is extensive navigation in the lower regions of the river, particularly from Portland to the Pacific, but the degree to which the river is navigable diminishes upstream because of the increasing number of rapids, and reefs which offer serious obstruction to free navigation. Contemplated future possible improvements of the upper portion of the river are based upon plans for securing slack water navigation by means of a series of locks and dams. When completed to its ultimate height the Rock Island dam will provide a navigable pool about 14 miles long at low water. To permit the possible use of this pool for navigation, the structure has been so designed that a lock could be constructed on the river bank opposite the power house in place of a portion of the present abutment.

Perhaps one of the most interesting features of the development is the pair of fish ladders provided for the passage of salmon which are going upstream in varying quantities at practically all times. Because of the importance of maintaining the fish run, careful study was given the problem of getting them over the dam until final plans were worked out in conjunction with state and federal authorities and a ladder was constructed in each abutment. Each of these ladders is some 500 ft long and provides 45 steps each 1 ft high, 10 ft long, and 20 ft wide. Sufficient water is used to assure a depth of more than a foot over the weirs, thereby permitting the fish to swim readily from one pool to the next rather than forcing them to jump. It is almost impossible to see the fish progress through the ladder, but the presence of a normal number of salmon at points up the river indicates satisfactory operation.

POWER HOUSE

The power house, also of concrete, is built into the dam adjacent to the north abutment and, while the present building will accommodate only the initial 4 units, the foundations are in for the ultimate 12 turbines which will require a building 880 ft long. That the power house design embraces several unusual features may be seen from the accompanying illustrations. Perhaps one of the most interesting of these arises from the necessity of providing for the possibility of extremely high tailwater by eliminating from the building all windows and other exterior openings below the main deck, which is about on a level with the roof of the generator room. In the office bay and the control room, located above the deck, the design provides for the normal proportion of windows, but throughout the plant excellent working conditions under close control are provided by artificial illumination and forced ventilation.

Air conditioning equipment is installed in connection with the ventilating system and even with the extremes of temperature of the eastern Washington climate satisfactory temperature control is obtained. Winter heat is provided by drawing warm air from the generators and forcing it to all parts of the building with blowers, together with sufficient air drawn in from the outside to keep conditions at the proper point. In summer the generators are closed and their heat absorbed by air coolers, and fresh air after being properly conditioned is circulated throughout the entire building. In addition to the ventilating and lighting system there is a complete system of tile drains laid in the substructure walls to intercept seepage through them and convey it to a sump whence it is removed by pumps.

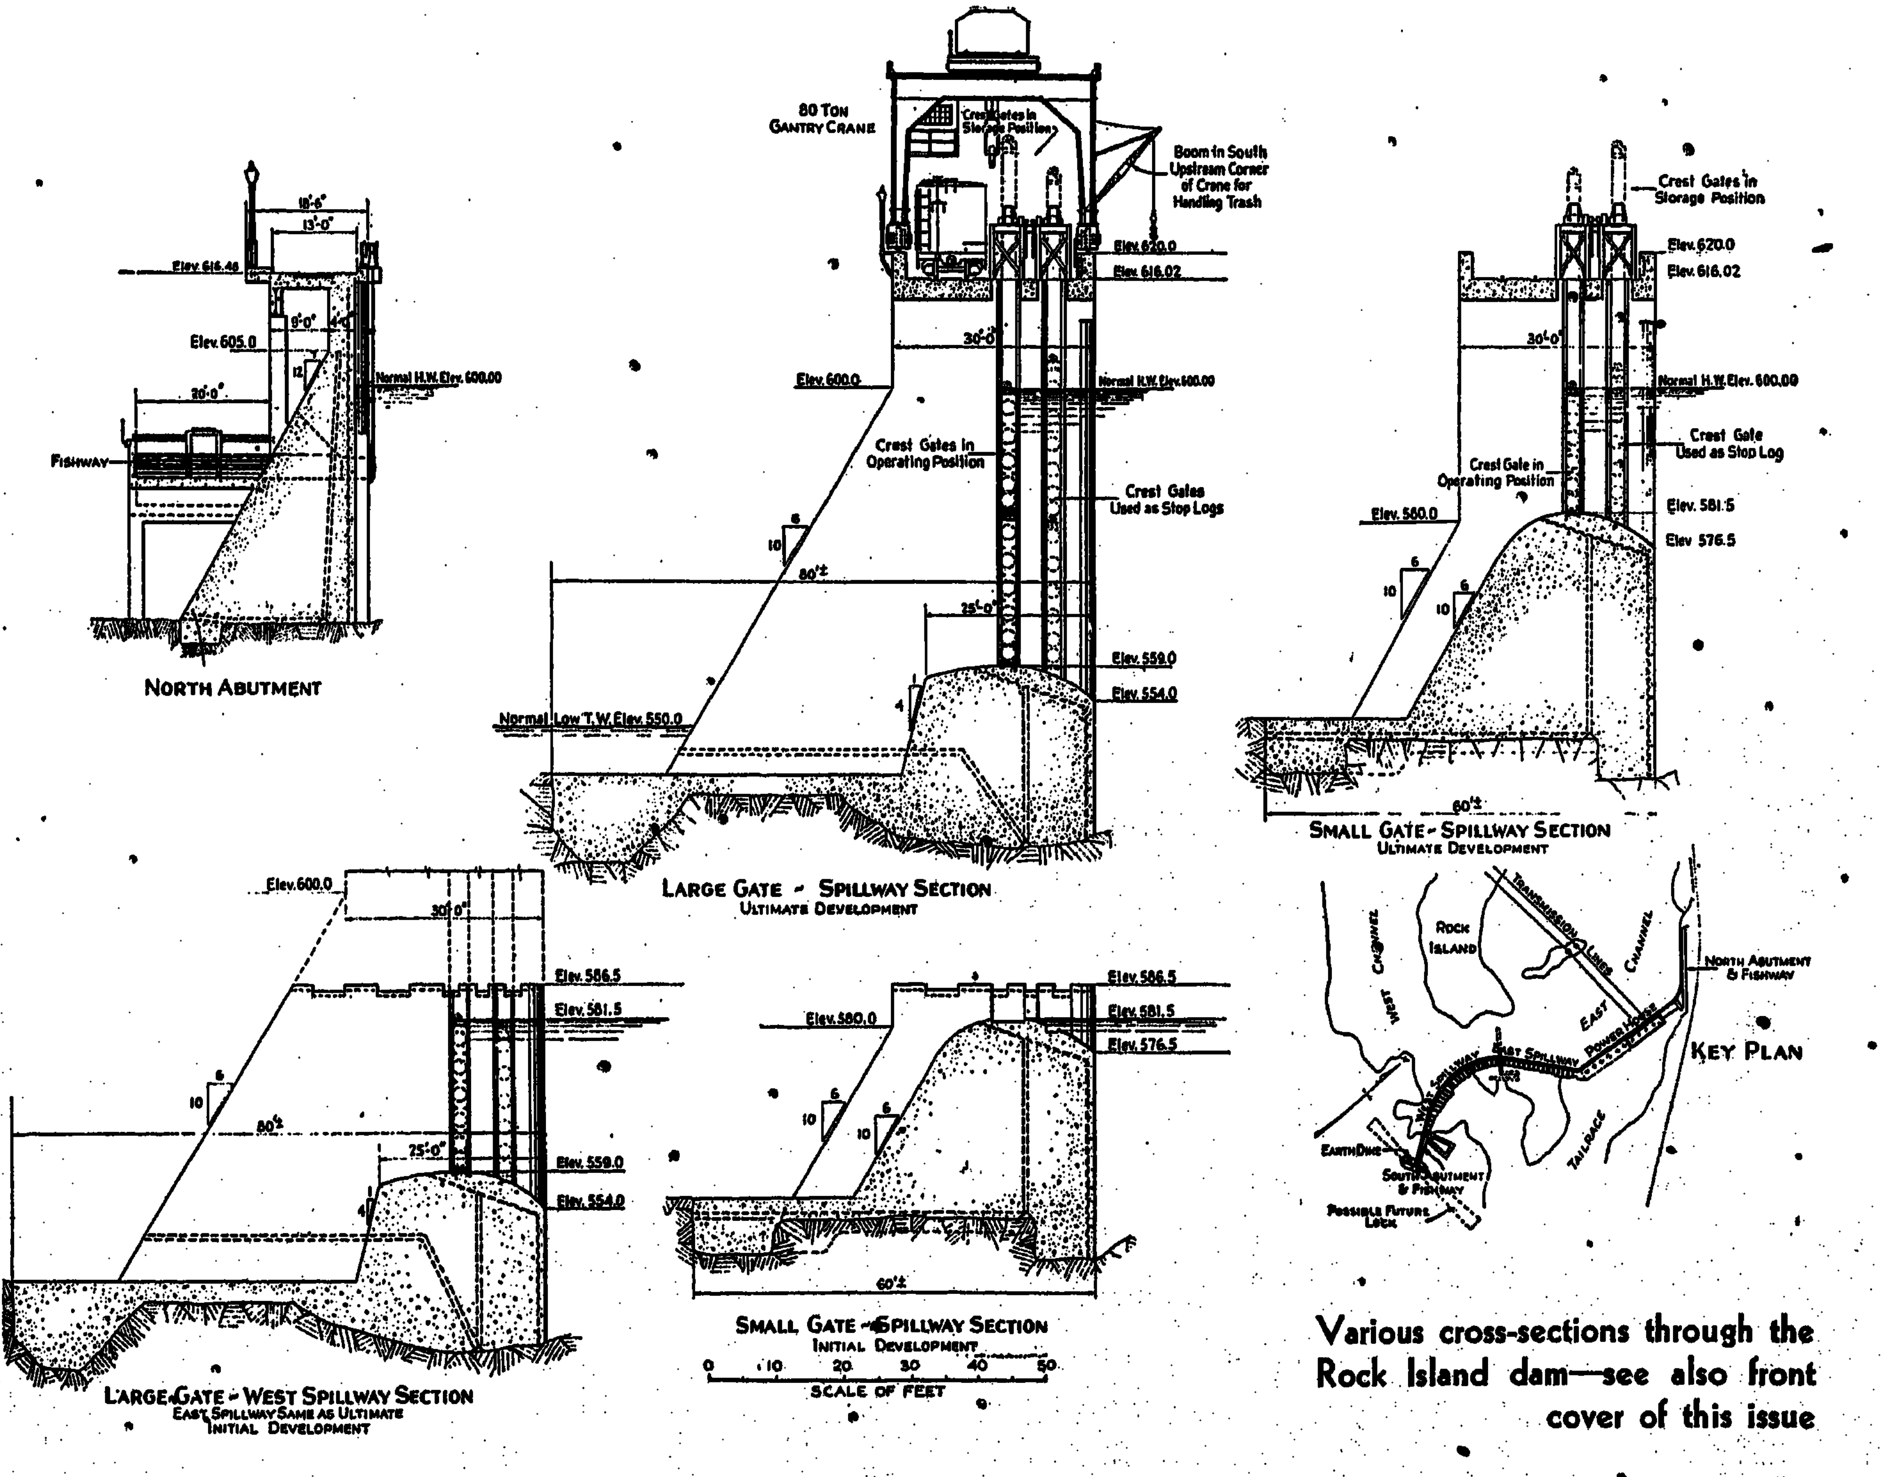
### WATERWHEELS

Waterwheel equipment as selected for the Rock Island plant has been designed to enable the production of as much power as possible under a reduced head, and at the same time to enable operation under normal conditions without an excessive decrease in operating efficiency. These wheels will develop 21,000 hp, equivalent to normal generator capacity, under a head of 32 ft, although they are designed to operate efficiently under a head of 48 ft. Each wheel will produce about 9,500 hp under a 20-ft head.

The initial installation consists of 4 vertical shaft units rated 21,000 hp at 32-ft head. These wheels are of the propeller type, with adjustable vanes selected because of the low and varying head conditions, and they constitute one of the largest installations of this type in the United States. The cast steel runners are 18.75 ft in diameter, are designed to operate at 100 rpm under heads varying from 20 to 48 ft, and carry 6 vanes each. To maintain capacity as high as possible at low head, and efficiency as high as possible at high head, the vanes are adjustable by means of a geared operating shaft which extends up through the hollow turbine shaft to the coupling between the turbine and the generator. Adjustments can be made only with the machine at rest, when changes may be made in from 5 to 10 min with the aid of a portable air motor. To protect the gear mechanism from water the runner hub and the gearbox are filled with a cup grease kept under high pressure.

The reinforced concrete scroll case for each wheel is directly connected to an intake opening in the face of the dam, and each opening is divided into 3 headgate sections each 27 ft 11 in. high by 15 ft 4 in. wide. Closure of the intakes may be secured by the insertion in each section of 2 steel gates fitted with rubber seals. Protection from drift is provided by trash racks made up of steel bars spaced on 12-in. centers and so arranged that electric heating may be used if required to combat ice. In addition to this a concrete curtain wall is placed upstream from the racks extending some 8 ft below minimum headwater level, serving effectively to fend off floating logs and ice.

The flow of water through the wheels is regulated by welded steel wicket gates 9 ft high and controlled by oil pressure governors whose flyballs are gear driven from the turbine shaft. As is usual with



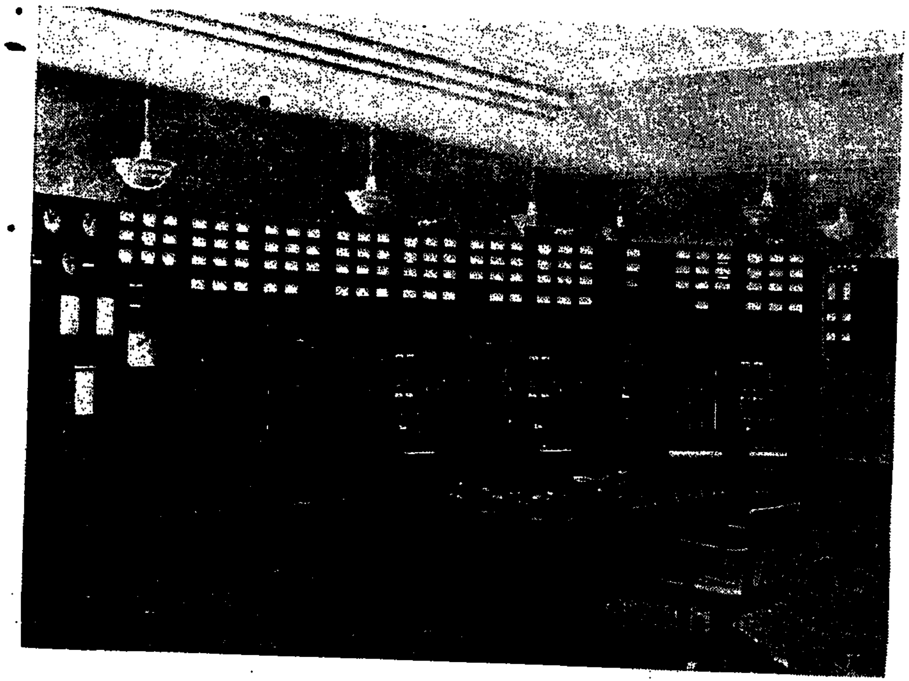
**Various cross-sections through the Rock Island dam—see also front cover of this issue**

this type of turbine, the wheels are set below normal tailwater and for access to a wheel it is necessary that the draft tube be closed as well as the headgates. Steel stoplogs are provided for insertion at the discharge from the draft tube and, with headgates and stoplogs in place, 2 vertical pumps each of 5,000-gpm capacity are used for unwatering the scroll case and draft tube. The draft tubes are of modified elbow design.

## Electrical Equipment

The generators are of the umbrella type each with combined guide and thrust bearing below the rotor; each is rated 16,667 kva, 13.7 kv, 0.90 power factor, 60 cycles. Each stator has an over-all diameter of 28 ft 8 in. A closed recirculating type of ventilating system equipped with air coolers of the surface type is provided for each main generator. Welded steel construction is used throughout and the rotor is of especially rugged construction to withstand the runaway speed of 230 per cent of normal. Excitation is provided by 250-volt main and pilot exciters mounted on the top of each generator shaft, and voltage control is secured by automatic rheostatic voltage regulators on each unit. The neutral of each generator is connected through an oil circuit breaker to a bus which is grounded through a resistor.

Each group of 2 generators is connected through their respective oil circuit breakers to a 13.8-kv bus from which power is fed through a transformer bank to a 110-kv transmission line. Each bank of 3 single-phase transformers has a rating of 30,000 kva with self-cooled operation, and 45,000 kva with forced air cooling. High-speed solenoid-operated oil circuit breakers are installed between the generators and the bus and between the bus and the transformer. A 13.8-kv transfer bus provides a means of erconnecting the stub buses, should operating itions require it. All bus work including the transformer deltas are of copper bars and are housed in indoor concrete cells. Each of the 2 main transformer banks is connected to an outgoing 110-kv line through a motor-operated disconnecting switch which is controlled from the switchboard and interlocked with the oil circuit breaker on the low voltage side to prevent the disconnecting switch from being used to interrupt power. All generators, buses, and transformers have individual differential protection, but no overload. Directional ground, and impedance relays open the 13.8-kv circuit breakers on the transformers in case of trouble on the transmission lines.



The Rock Island control board uses steel panels both front and rear. Indicating meters and control switches are mounted on the front panels; recording meters and relays on the rear panels

The control board is shown in one of the accompanying illustrations. Individual panels are assigned to each generator and to each transformer; 2 panels are used for graphic frequency meters, totalizing meters, voltmeters, and special instruments. Control board wiring is carried on brackets along the edge of each panel and brought down to terminal blocks in a special box in the room directly below the board. Except where walls and mass concrete prevent, wiring is in exposed conduit, and a special room is provided below the electric bay for conduit racks.

Because of the importance of auxiliary equipment in a station of this size, two sources of station power are provided. A 1,760-kva 460-volt vertical generator driven by a propeller waterwheel rated at 2,100 hp at 32-ft head is the primary supply; a 1,760-kva 3-phase transformer provides a secondary supply from the 13.8-kv transfer bus. The 460-volt bus is sectionalized with automatic air circuit breakers to isolate any section that might be in trouble. All important auxiliaries are served by duplicate feeders energized from different sections and equipped with automatic throw-over switches.

## General Information

For the handling of the heavy generating equipment, 2 80-ton cranes are installed in the generator room, each having also a 15-ton auxiliary hoist. Special lifting devices are used on the larger parts to reduce the headroom required for their handling. An 80-ton gantry crane with automatic blocks is used for operation of the crest gates and the head gates. Another 20-ton gantry is provided on the tailrace deck for setting the draft tube stoplogs. A 75-ton transfer crane which traverses the building is used for handling material to and from the tailrace deck, and also for the transfer of materials and equipment from standard cars on the deck through a hatchway in the ceiling of the generator room to the floor below.

To give an idea of the size of the project and the quantities involved, the following few figures are quoted:

| | |
|---|---|
| Reservoir area | 3,000 acres |
| Total estimated excavation | 335,000 cu yd |
| Total estimated concrete | 235,000 cu yd |
| Total ultimate length of power house | 886 ft |
| Total length of dam and abutments | 3,500 ft |

The initial development when completed will make available in an average water-year about 480,000,000 kwhr, whereas the ultimate installation is expected to produce about 1,220,000,000 kwhr annually. This latter figure is equivalent to running the contemplated 150,000-kw capacity continuously at full load for 93 per cent of the time.

In addition to the more usual exploration and test borings on the dam site, and observations and measurements of stream flow, a laboratory model of the entire dam site was made in order to check the flow condition and the discharge capacities of the proposed structures. This model represented a 6,000-ft stretch of river 3,000 ft wide and was made on a scale of 100 to 1. Upon this were built models of the proposed dam and power house, and water in the proper amount was allowed to flow through these structures to give an index of the correctness of design. Cofferdams also were included in the model experiment in order to determine in advance the required height of the necessary cofferdam for both channels of the river under the various flow conditions that were to be expected during the construction period. Observed water levels at the dam site resulting from construction of the actual cofferdam agreed closely with the advance expectations based upon the laboratory model experiment.

# Abstracts

## Of Papers to Be Presented at the Baltimore District Meeting

INTERPRETIVE abstracts of all papers which at the time of this issue are definitely scheduled for presentation at the A.I.E.E. Baltimore District meeting (Oct. 10–13, 1932) are published herewith. In response to popular demand and within its space limitations ELECTRICAL ENGINEERING subsequently may publish certain of these papers, or technical articles based upon them.

Members vitally interested and wishing to obtain a pamphlet copy of any paper available in that form may do so by writing to the A.I.E.E. Order Dept., 33 West 39th Street, New York, N. Y., stating title, author, and publication number of each paper desired.

## 115-Kv Submarine Cable Crossing of the Columbia River

By
E. F. Pearson[1]
G. B. Shanklin[2]
W. R. Bullard[3]
S. B. Clark[1]

THE FIRST submarine installation of oil filled cables in this country has been made. It is a 115-kv cable crossing the Columbia River just north of the city limits of Portland, Ore. The selection of a nominal transmission voltage of 110 kv was determined by an economic analysis based on various schemes of delivering energy to load centers in the Portland area. Conditions were found favorable for laying the cable directly on the bed of the river without the digging of a trench. Three cables were laid 4 ft apart, and the shore ends above extreme low water were trenched in and covered with 4 ft of sand. Oil filled cable was found to possess many advantages for this particular service and therefore was specified instead of cable with solid insulation.

The present paper, in addition to giving the reasons underlying the principal decisions regarding the cable, includes a section on the design and manufacture of the cable and accessories, a description of the design of features incorporated in the field installation, and the procedure followed in making the actual installation. Many unusual construction problems were encountered but by careful planning were solved successfully and operation of the cable under normal conditions since June 19, 1932, has been very satisfactory. Cable temperatures and oil level fluctuations have followed very closely the values calculated for varying load conditions. (A.I.E.E. paper No. 32-125)

## Thermal Transients and Oil Demands in Cables

By
K. W. Miller[4]
F. O. Wollaston[5]

SINCE underground power cables almost always operate under variable loading, it is desirable to establish their allowable carrying capacities on the basis of variable loading rather than upon the basis of some equivalent steady state loading, as is the present practise. For this purpose it is most useful to know what temperature variations will occur at any point in the cable at any time due to an abrupt change from one constant load to another. Then any load curve can be handled with sufficient accuracy by breaking it up into a series of rectangular steps, and adding with proper time intervals the successive thermal transients.

The fundamental equations were developed several years ago, but the numerical solution was too complicated and laborious to be of general practical value. A simplified method is presented in this paper, which employs calculating charts and other devices permitting exact and complete solutions to be obtained and verified in one day, in contrast to approximately one week as required by the former methods. The theory has been verified by measurements on actual cables of the ordinary and oil filled type. In addition to solutions for temperature transients due to abrupt load changes, precise simplified solutions for the following related phenomena are given:

1. Oil demands due to abrupt load changes in oil filled cables.
2. Temperature transients and oil demands due to load variations of any kind, whether abrupt or otherwise.

Although the methods described in this paper were developed for problems of single-conductor cables, they can be applied also directly to 3-conductor cables, using a per phase basis. For oil filled 3-conductor shielded cable with round conductors, the accuracy will be excellent. If the conductors are sector shaped, good accuracy may be obtained by using the equivalent round conductors. For ordinary

3-conductor cable with solid fillers and no shielding, the accuracy will be only fair.

The duct temperature transient is of importance in problems of variable loading, but has not been adequately investigated; further work should be done along this line. Some of the constants needed for use in thermal and oil-flow problems of cable insulation are relatively new; many of the values now in use for these constants are based upon only a few scattered observations and further laboratory and field data should be obtained. (A.I.E.E. paper No. 32-127)

## Traveling Wave Voltages in Cables

By
H. G. Brinton[6]
F. H. Buller[2]
W. J. Rudge, Jr.[6]

When a traveling wave on an overhead line reaches a cable, a wave of reduced voltage passes into the cable. This reduction is due to the fact that the surge impedance of a cable is less than that of an overhead line. In a traveling wave the electrostatic energy is equal to the electromagnetic energy, and the constants of a cable are such that the voltage of a traveling wave has a lower ratio to the current than in the case of a wave on an overhead line. After the wave enters the cable there are voltage and current reflections back and forth from each terminal. If the length of the original wave is great enough, there will be several superimposed waves at each point in the cable. The sum of these several waves will be dependent upon the shape of the original wave as well as upon the reflections.

The reflection at the cable terminal depends upon the surge impedances of the cable and of the connected line or apparatus. In this paper, calculated values of voltage are given for a range of cable surge impedance from 20 to 150 ohms, and line impedances of 300 and 500 ohms. The calculations include the case of similar lines connected to each end of the cable, and the case of a line connected to one end of the cable only with a free terminal at the other; this latter arrangement gives the higher voltage. The traveling wave is assumed to enter at the "near" end of the cable and the voltage at the "far" end is calculated, since in general the maximum voltage will be found at that end. Reduction of the wave by cable losses is neglected, as tests have shown the losses to be small in 500-ft and 1,000-ft lengths of cable.

Among the results brought out in this paper are the following:

1. Short wave fronts do not greatly affect the ultimate voltage resulting in the cable.
2. Cable voltage is greater for waves which decrease more slowly with time. This difference is more pronounced for the shorter lengths of cable.
3. A higher surge impedance of the line results in a lower voltage in the cable. This effect is greater with longer cables.
4. Cable voltage varies widely with different cable surge impedances, the voltage decreasing with the impedance.

A practical example is worked out in the paper, and suggestions are made for lightning arresters to limit the high voltage impulses. (A.I.E.E. paper No. 32-118)

## Voltage Regulation of Cables Used for Low Voltage A-C Distribution

By
H. R. Searing[7,8]
E. R. Thomas[7]

Distribution of alternating current at low voltages does not depend primarily upon the selection of a conductor size which is thermally adequate, but depends upon the voltage regulation limits which will be satisfactory for lighting, especially when combined lighting and power loads are carried on the same circuit. Voltage regulation of a-c circuits is a function of the magnitude of the current, the power factor, and the circuit impedance. With currents of lower power factor, the inductance component of the impedance becomes the major parameter affecting the voltage regulation, and for a particular circuit and load, there is an optimum ratio of resistance to reactance. While the resistance per unit length of circuit is variable, depending only upon the physical size of the conductor, the reactance per unit length is almost independent of the physical size of the conductors, and for a single circuit with cables, can be changed only by changes in cable construction.

Thus in order to obtain a certain optimum ratio of resistance to reactance for a circuit, there are in general 3 courses of attack; first, for a given physical size the reactance component may be changed by changing the cable construction (the use of single conductor cable or multi-conductor cable employing either sector or concentric construction); second, by changes in the physical size of the conductor; and third, by paralleling 2 or more circuits.

The relative voltage regulations of the different types of cable are given in curves presented in this paper, and it is shown that the regulation efficiency (that is, the amperes per 1,000 cir mils which will give one per cent voltage regulation per 100 ft on a 3-phase 4-wire 120–208-v circuit) improved with the smaller wire sizes of cable. It is further shown that the concentric type of cable has the greatest efficiency, the sector type the next best efficiency, and the single conductor the poorest efficiency, with the twin circuits of single conductor cable lying between the values for single conductor cable and sector type. These data are adjusted for cost of cable at the factory and installed in the field, and it is shown that of the sizes of cable usually found in practise, 500,000-cir mil concentric construction provides the most economical means for transmitting low tension alternating current where the cable is not required to be worked alive. For cable mains, however, where it is necessary to work on live cables, the use of twin circuit 4/0 single-conductor cables is the most economical. Various phase relations between the several conductors are discussed. Test results indicate close agreement with the calculated values. (A.I.E.E. paper No. 32-119)

## Pulp Insulation for Telephone Cables

By
H. G. Walker[11]
L. S. Ford[12]

Pulp insulation is a new type of insulation that has been developed to replace the well known spirally wrapped ribbon paper insulation in certain kinds of telephone cables. It consists of a continuous pulp sleeving formed directly on the wire by a modified paper making process. The raw material for this insulation is commercial Kraft pulp and its preparatory treatment in the beaters corresponds to that given in the regular paper making process.

The machine used to apply this pulp to the wire is a modified single cylinder paper machine equipped to insulate 60 wires simultaneously. The wires are taken from the supply spools by means of flyers so as to allow the brazing of the wire from a nearly empty spool to the wire on a conveniently located full spool. This gives continuous operation. The wires are fed to the machine through an electrolytic cleaner for the removal of residual drawing compound. The surface of the mold or paper forming mechanism is divided into 60 narrow portions in such a way as to form that many narrow sheets continuously. The wires are brought into contact with the mold in such a way that as it rotates and forms the sheets, a single wire is embedded in each sheet. These sheets and wires are transferred from the mold to a traveling wool blanket by the pressure of the couch roll. The traveling blanket carries the sheets and wires through the presses for dewatering and consolidating, and delivers them to the polishers where the sheet is turned down by a rapidly rotating mechanism into a cylindrical wet sleeve surrounding the wire. The moisture is driven from the wet insulation by passage through a box type electric furnace one end of which is maintained at a rather high temperature. The insulated wire then is taken up on spools ready for the twisting operation. The speed of the machine is about 130 ft per min.

The major difficulties in the process have been overcome and the basic properties of the insulation have been determined. Equipment for the production of about 225,000,000 conductor feet per week has been provided and the entire output of 24 and 26 A.W.G. cables is being made in pulp.

These cables are designed to the same size as the ribbon paper cables which they replace and compare favorably with them in their electrical characteristics except that the mutual capacitance is slightly higher. The impairment in transmission efficiency due to the higher capacitance is more than offset, however, by the lower first cost of the cable.
